The increase in the power load is partly shown by Curve III., which gives the total horse-power of motors connected. This has risen from 1,030 to 2,494 h.p., an increase of 142 per cent. Curve IV. shows the total connections for both lighting and power expressed in the equivalent number of 8-c.p. lamps. This figure has increased by 18·4 per cent. in the three years. The last curve shows the increase in the kilowatts connected for heating and power other than motors. This amounts to 184 per cent., the figure having increased from 578 kw. in 1906 to 1,642 kw. in March, 1909. Included under this heading is a considerable amount of battery-charging plant, most of which is owned by private individuals. In the year 1906–7 eighteen such plants were connected, and in 1908–9 twenty-two, the total capacity in the last case being over 100 kw. These plants vary in size from large electric automobile garage charging sets to quite small sets for charging ignition batteries. Another item included under the heading of power other than motors is the electro-medical apparatus; there is 125 kw. connected in X-ray apparatus alone, and over 120 kw. in light and heat baths. As mentioned in our columns some weeks ago, the number of electric radiators in use in Marylebone has increased considerably of late; there are now over 650 connected.

In conclusion, we should like to acknowledge our indebtedness to Mr. F. H. Davies, the commercial engineer to the Electricity Department of St. Marylebone, through whom these statistics were obtained.

FOLKESTONE, SANDGATE AND HYTHE TRAMWAYS

Trolley, Conduit, or Surface-Contact System

THE Committee of the House of Commons which is considering the Bill of the National Electric Construction Co., which proposes to vary an existing agreement between the company and the local authorities of Folkestone, Sandgate, and Hythe, for the construction of tramways, adjourned on Friday until to-day. The objects of the Bill are briefly these. In the year 1901, the Folkestone Corporation obtained Parliamentary powers to construct tramways in their district, but in 1906 these were transferred to the National Electric Construction Co., who thereupon entered into an arrangement with all three Councils to construct tramways in their districts upon the Dolter surface-contact system, or some similar system, should the Dolter system prove unsuccessful. Since then, however, the company has had a rather unpleasant experience with surface-contact systems, for not only did they have to replace the Dolter system between Mexborough, Rawmarsh, and Swinton by the overhead system, but the Board of Trade have refused to grant a permanent licence for the running of the Torquay lines, which, in fact, the company believe will eventually have to be replaced by the overhead system. Indeed, an extension to Paignton is definitely to be upon the trolley system. Again, a considerable sum of money has been spent at Oxford in an unsuccessful endeavour to convince the Corporation of the suitability of the Dolter system. This endeavour, however, together with recent events in London, seems to have convinced the company that the handling of surface-contact systems is not, at present, likely to be a pronounced commercial success; at any rate, it has been found impossible to secure the necessary capital. Consequently, in spite of opposition from Folkestone, Sandgate, and Hythe, it is now proposed to abandon the use of a surface-contact system in these districts, and to substitute the overhead system, with the exception of certain roads in Folkestone, over which Lord Radnor, who is lord of the manor, has absolutely refused to have the overhead system. In these roads, the conduit system will be installed. It is worthy of mention that on several occasions both Sandgate and Hythe have agreed to the overhead system; but as different decisions were come to almost every week upon the occasions when the subject has been prominently before the public, perhaps too much need not be attached to this. More than one councillor will be ready to admit that resolutions have been passed at times, of which, although he voted in favour, he had but little knowledge of what they contained, so chaotic did the proceedings become. Nevertheless, one absolute certainty exists, and that is that the company, although not a yard of tramway has been laid, have paid over to the local authorities a sum of no less than £23,000 in respect of street widenings. The position of Folkestone in the matter now is that they want conduit or surface-contact throughout, whilst Sandgate and Hythe ask that the Lorain surface-contact system should be laid down.

On these facts being placed before the Committee, the Chairman announced they had come to the conclusion that all surface-contact systems were unsuitable, and that the conduit was too expensive. This immediately produced from the counsel for Sandgate and Hythe a confident assertion that they could prove conclusively to the Committee that the Lorain system would be a perfectly satisfactory one, and as the promoters had merely stated in general terms their objections to this system, the onus was put upon them to dispose of it more effectually. Consequently, Mr. J. E. Waller, of Messrs. Kincard, Waller, Manville & Dawson, was called, who refused to have anything to do with the Lorain system because the Lorain Steel Co. would not give a guarantee in the same way that one was given to Wolverhampton. His opinion, and also that of Mr. Stephen Sellon, who was called by the promoters later, was that the Wolverhampton Corporation had been granted special terms, and that having gone in for it they were bound to continue. Emphasis was placed upon the fact that in no other place in the world was the system in operation.

All this carried the proceedings up to Friday, when the case for the promoters was closed. For the Folkestone Corporation, Mr. C. E. C. Shawfield, Chief Electrical Engineer to the Wolverhampton Corporation, was called, and his evidence was also relied upon by Sandgate and Hythe. He detailed the history of the negotiations with the Lorain Steel Co., and stated that if the Wolverhampton Corporation had to commence their system all over again, they would most certainly have the Lorain system. On the question of cost, in spite of the statement that the Corporation had been granted terms which the Lorain Steel Co. would not grant again, extensions of the system were now being carried out which would cost less than did the original lines.

As stated above, the Committee will resume consideration of the Bill to-day (Thursday).

INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION

Full Programme of the Manchester Convention

THE full programme of the Fourteenth Annual Convention of the Incorporated Municipal Electrical Association, which will be held in Manchester from June 21st to 25th inclusive, is now available.

On Monday, June 21st, there will be a reception and conversazione at 7.30 p.m., at the Town Hall, Albert Square, by the Right Hon. the Lord Mayor of Manchester (Alderman Edward Holt, J.P.).

At 10.30 on Tuesday, June 22nd, the Association will meet in the Large Lecture Hall of the Municipal School of Technology, Whitworth Street. The Right Hon. the Lord Mayor of Manchester has kindly consented to welcome the Association. The first business will be the Presidential Address by Mr. S. L. Pearce, Chief Electrical Engineer to the Manchester Corporation, which will be followed by a Paper entitled "Cheap Units," by Councillor A. Sinclair, Member of Council, and Chairman of the Swansea Electricity Committee. At 1.15 p.m. the Association will be entertained at luncheon by the Manchester Electricity Committee in the Large Hall. Special cars will afterwards convey the members to the Stuart Street, Dickinson Street, and Bloom Street generating stations of the Manchester Corporation.

The meeting on Wednesday, June 23rd, will be at Liverpool. A special train will leave Manchester (Central) at 8.55 a.m., returning from Liverpool Central at 9.20 p.m. Sir Charles Petrie, Chairman of the Tramway and Electric Power and Lighting Committee of the Liverpool Corporation will welcome the Association at 10 a.m. in the Small Concert Hall of St. George's Hall, Lime Street. The following Papers will be read and discussed:—(1) "The Influence of Metallic Filament Lamps on the Electrical Industry and on Street Lighting," by E. E. Hoadley, Chief Electrical Engineer, Maidstone; (2) "Modern Cable Systems," by E. M. Hollingsworth, Chief Electrical Engineer, St. Helens. The Liverpool Corporation Tramways and Electric Power and Lighting Committee give a luncheon at 1 p.m., at the Exchange Hotel (Lancashire & Yorkshire Railway). Special cars will leave there at 2.30 p.m. for the Lister Drive generating station of the Liverpool Corporation, and at 4 p.m. a move will be made for Pierhead, for a visit to the R.M.S. *Maurctania*, where tea will be served in the saloon.

On Thursday, June 24th, a meeting will be held in the Large Lecture Hall of the Manchester Municipal School of Technology, Whitworth Street, when the following Papers will be read and discussed:—(1) "Steam Turbines from the User's Point of View," by A. S. Blackman, Chief Electrical Engineer, Sunderland; (2) "Notes on Condensing- and Water-Cooling Plants" (Travelling Studentship Prize Paper, 1909), by E. Lunn, Assistant Electrical Engineer, Huddersfield. In the afternoon a visit will be paid to the works of the British Westinghouse Co. at Trafford Park, and at 7 p.m. the Association annual dinner will be held at the Midland Hotel.

The annual general meeting will be held at the Municipal Technical School at 10.30 a.m. on Friday, June 25th. The Frederick Road Electricity Works of the Salford Corporation will be visited in the afternoon; the Radcliffe power station of the Lancashire Electric Power Co. will also be open to members of the Association.

In addition to the visits arranged for Thursday and Friday afternoons, the following will be available as alternative visits:—Lancashire Dynamo & Motor Co.'s works; Electromotors, Ltd., works; Hyde Road car shed of the Manchester Tramways Department; Manchester Municipal School of Technology; Polygon Substation and Testing Department of the Manchester Corporation; Messrs. Connolly Bros.' works, Blackley; and the generating stations of the Bolton, Bury, and Oldham Corporations.

INTERPOLE DESIGNS

MR. W. B. HIRD, of Messrs. Mavor & Coulson, Ltd., read a Paper on Tuesday, May 11th, before the Glasgow Section of the Institution of Electrical Engineers, on the subject of the application of commutating poles to continuous-current machines of normal design. The author points out that for abnormal machines such as turbo-generators, and extra-high speed, variable speed, and reversing motors, the application of interpoles is generally admitted to be the best method of ensuring satisfactory commutation, but that there is still considerable difference of opinion as to whether the use of interpoles is legitimate in the case of those machines which can be satisfactorily designed without using any special commutating device. In spite of warnings from high quarters, he says, the use of interpoles in normal designs—that is, in machines running at moderate speeds and of ordinary output—is becoming more and more frequent, and it is becoming more and more usual to find interpole machines specified by users, who prefer them to ordinary machines.

Before dealing with the question at issue, the author explains the principle of the interpole, and gives a formula for use in its design. Incidentally, he mentions the fact that the number of interpoles may be made less than the number of main poles. A 4-pole machine, for instance, may have only two interpoles. The field strength of each interpole must, in this case, be calculated to give twice the voltage which would be required if there were four. This arrangement, he says, gives good results on small machines up to 20 h.p., in which the reactance voltage is not excessive, but has not been found satisfactory in machines of any considerable size.

In order to justify the use of interpoles, the author continues, where a good workable design could be obtained on ordinary lines, it must be shown that a machine can, by the use of interpoles, be made either better or cheaper. To take first the question of cost. The material and labour expended on the interpoles are balanced by the saving due to the fact that the reactance voltage may be considerably increased without spoiling the commutation. The directions in which economy is obtained are the use of a reduced depth of air-gap, allowing of smaller magnets carrying less copper; reduced number of commutator parts, saving both labour and material in the commutator; and lastly, the possibility of working with a greater length of armature core relatively to the diameter. In present practice the length and diameter are not chosen so as to make the machine most economical in first cost, and greater relative length would almost invariably conduce to a lower cost price. By plotting a curve showing the relative costs of machines of different lengths but of the same diameter, and putting several such curves for different diameters on the same sheet, with d^2l as base line, the points where these curves cross show the different lengths at which it is advantageous, from the point of view of economy in first cost, to pass from one diameter to the next larger diameter. If such curves are drawn out for any given line of machines, it will be found that the economical lengths for the different diameters taken are considerably in excess of those usually met with. Thus, in some cases worked out by the author, the value of d^2l, at which it becomes as cheap to make a 15-in. diam. as a 12-in. diam. armature, is about 3,500, corresponding to a length for the 12-in. armature of 24 in., and the point where the 15-in. and 18-in. curves cross corresponds to $d^2l = 5{,}800$, or a length for 15-in. armature of 26 in. In any case, the point to be emphasised is that in any line of machines being manufactured, such a series of curves, plotted with the actual figures obtained by experience, will show the most economical length of armature core for any given diameter, and it is believed that in the vast majority of cases they would show that the economical length is much greater than any at present in use. This statement, however, is true only on the assumption that the output increases proportionately to the length. In ordinary designs the increased length leads to impossibly high reactance voltage long before the economical length is reached; but if interpoles are used this sparking limit is removed.

The question then arises as to whether the heating limit of output will not prevent the output of the machine being increased proportionately to its length. A long armature core dissipates the heat generated less readily than a short one, and when the length becomes so great as to require increased diameter of shaft, stronger spider, &c., the increased impediment to the

Digitized by Google

circulation of air in the inside of the core makes the increased temperature rise more marked. When this limit to output is reached, it would appear that some method of forced ventilation might be devised to remove it. Something more is wanted than merely stirring the air with fan blades—a definite circulation along a predetermined path is required. Present interpole designs rely mostly on the saving to be obtained by the use of reduced air-gaps and smaller commutators with fewer parts, and do not take full advantage of the increased lengths made possible, but if more ventilation can be obtained so as to remove the heating limit, still greater advantage will be derived. There is further to be considered the question as to whether a machine for ordinary outputs will be improved or the reverse by the introduction of interpoles and by the modifications of design which this involves. Good results are obtained in the case of abnormal machines, and there does not appear to be any reason why equally good results should not be obtained on machines of normal output. It is not an uncommon experience to find modern generators having a reactance voltage so nearly up to the highest safe value that if the brushes are not in exactly the best position, or if the commutator has been allowed to get at all out of condition, they will flash over from brush to brush if the load be suddenly thrown off. Cases of that kind appear to be entirely removed by the use of interpoles, and there seems every reason to believe that their extended use would lead to better machines, as far as commutation is concerned. It may be true that there is some fear that mechanical troubles may arise with machines in which the air-gap is smaller, and the length between bearings greater than in present practice, but the air-gaps for interpole machines are still made greater than those of induction motors, and the longer armature lengths suggested still give a reasonable ratio of length to diameter. On the score of efficiency it may be contended that increasing the losses to such an extent as to require forced ventilation will lower the efficiency of the machine. But the increased losses correspond to a more than proportionately increased output, and therefore to a better efficiency. In conclusion, the author submits that the logical consequence of the use of forced commutation is an increase in armature lengths which may necessitate the introduction of forced ventilation, and further that this appears to be the means more immediately at hand of progressing towards the smallest and cheapest satisfactory machine for a given output.

DISCUSSION.

Mr. W. W. LACKIE (City Electrical Engineer, Glasgow), Chairman, remarked that the characteristic of a shunt generator with interpoles approached that of a compound wound machine, and consequently on a short-circuit occurring, it was found that there was a tendency for the interpole machine to feed back on to the others. Proposals had been made to overcome this difficulty, but so far as he knew no satisfactory method had yet been devised of running ordinary shunt and interpole shunt machines in parallel. He thought that it would be advisable to use separately driven fans for large machines if forced ventilation had to be resorted to.

Mr. H. A. MAVOR (Mavor & Coulson, Ltd., Glasgow) confessed that he had for a long time resisted the introduction of interpoles, as he had looked upon the use of them as an expedient for getting rid of troubles which should not exist. But although this was perhaps the correct attitude in the early days of the industry when the principles of machine design were not so well understood, it was hardly correct now. He still thought that in most cases occurring in ordinary work it might be better to increase the diameter of the armature, and to use cheaper material, and so keep the reactance down, than to use interpoles to compensate for a reduced diameter of core and increased reactance.

Mr. WM. MCWHIRTER (Wm. McWhirter & Sons, Glasgow) remarked that it was not many years ago that the use of carbon brushes was supposed to have solved all reactance troubles, and to have practically eliminated the sparking limit, but at the expense of increased heating. Mr. Hird's argument was only a development of the same idea; but the heating effects had been increased to such a degree that it was necessary to resort to forced ventilation. He referred to the experiments of Mr. W. B. Sayers, of Glasgow, and other gentlemen, with compensating armature windings, and remarked that he thought the use of interpoles a much simpler method of attaining the object in view.

Mr. G. MCMILLAN (Electric Control, Ltd.) said that he had attempted to plot curves, similar to those mentioned by Mr. Hird, from which to deduce empirical formulæ for rapid estimating and for guidance as to how to reduce the cost of manufacture for A.C. machines—particularly single-phase machines. His experience proved that actual results gave anything but straight-line curves (those shown by Mr. Hird were approximately straight lines), as the increased size of shafting, bearings, &c., soon had a marked effect on the cost.

Mr. H. A. MAVOR spoke again in order to point out that although working out costs by means of such curves was of great interest, it must not be expected that the results would be of any great value in estimating. One had always to bear in mind that the cost of a machine was affected not only by the design, but by many other factors, such as the differences in cost of labour and material at different times, &c., and that, therefore, one could not rely upon such curves to indicate the cost of a machine within, say, 10 per cent. of the actual cost.

Mr. J. R. BARR (Heriot Watt College, Edinburgh) thought that the use of interpoles for any but special high-speed or variable speed machines was out of the question. The increased armature heating, the increased leakage from the main poles, and the reduction in clear ventilating space due to the use of interpoles, necessitated, in his opinion, such additions and alterations to the machine generally as would entirely offset any saving due to the higher reactance voltage permissible.

Mr. T. G. PEARSON asked if water cooling had ever been tried. He thought that it should be possible to get a satisfactory arrangement with hollow yokes, shafts, &c.

Mr HIRD, in his reply, said that the *raison d'être* of his curves was to show the point at which it became economical to proceed from one diameter of core to another. He did not suggest that it would be advisable to go to the extreme lengths indicated by such curves. Mr. Lackie's remarks applied principally to turbo-generators, whereas his Paper referred more particularly to smaller machines. The only suggestion he could make with regard to paralleling was that Mr. Lackie, and other central station engineers in the same predicament, should adopt interpole machinery entirely! The whole question of the design of D.C. machines was controlled by the sparking and heating limits. The sparking limit had been got rid of by the use of interpoles, and the next point was to get over the heating trouble. Water cooling had been experimented with, but it had been found that leakage and condensation were always present, and caused trouble with the insulation. The use of a separate fan could only be justified for large machines.

Electrical Control of Naval Ordnance.—Trials have just been concluded off Selsey Bill with a new system of electric control for heavy guns on board ship, the invention of Rear-Admiral Sir Percy Scott. A number of instruments are placed in the fire-control station in the foretop, and are connected with the motors of the elevating and swivelling gear in the barbettes. By this means all the guns are under the control of the gunnery officer in the foretop, and there is no gun-laying in the barbette itself unless the control station is disabled. The results of the trials are not yet published, but it is understood that the apparatus has given every satisfaction.

Telephone Rates in Australia.—New regulations, placing all the telephone systems in the Commonwealth of Australia on the measured-rate system have been approved by the Executive Council. According to these regulations, each subscriber will pay a sum varying between £2 and £4, according to size of town and number of parties included in the service, and a further charge of one halfpenny for every call made by the subscriber. After the total number of calls made have reached 2,000, additional calls will be charged for at the rate of three a penny up to the end of the year. The maximum length of a subscriber's line for the foregoing charges is two miles. For any further length of line the subscriber must pay for each quarter of a mile 10s. per annum for an exclusive service, and 5s. per annum for a two-party service.

Tour of the Institution Students.—It has been proposed by the Students' Committee that, following on the success of the tour to Switzerland in 1907, a tour might this year be made to visit the large engineering works in Germany. The matter has been discussed and some preliminary arrangements have been planned for such a tour. Permission is being asked to see, amongst others, the following works:—Messrs. Siemens & Halske, Messrs. Bergmann, the Siemens-Schuckert Dynamo Works, Allgemeine Elektricitäts Gesellschaft, Dr. Cassirer & Co., Charlottenburg Technical Institute, the Reichsanstalt, an electric railway, a gas-engine driven generating station in the neighbourhood of Cologne. The visit will take place during the second week in July, and the party will leave London on Friday evening, July 9th, arriving in Berlin on the Saturday evening. The visitors will remain in Berlin until the Thursday, and then proceed to Cologne, breaking up on the following Saturday. It is estimated that the tour should not cost more than ten pounds, and Messrs. Thos. Cook & Son have in hand the arrangements. The committee feel that this is a unique opportunity of seeing the German engineering works, and at the same time spending an enjoyable summer holiday, as arrangements can be made whereby any member of the party can continue his stay in Germany, if so desiring, for some days longer at a very slightly increased expense, the tickets being available for 25 days. All desirous of accompanying the party should communicate with the hon. sec., Mr. E. W. Moss, 20 Huddleston Road, Tufnell Park, London, N.

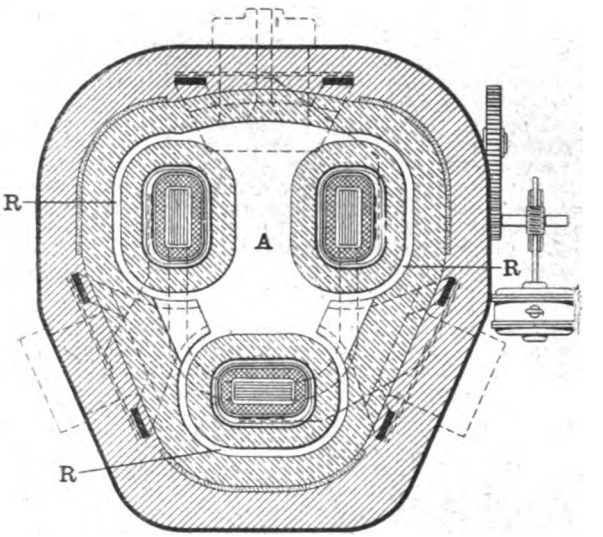
THE IRON AND STEEL INSTITUTE

THE fortieth annual meeting of the Iron and Steel Institute was held on Thursday and Friday last at the Institution of Civil Engineers, Westminster, under the presidency of Sir Hugh Bell. Included in the first day's proceedings was a Paper by Prof. W. H. Walker on the electrolytic theory of the corrosion of iron, which was discussed with two others relating also to the corrosion of iron and steel. The following is a brief abstract of this Paper:—

The Electrolytic Theory of the Corrosion of Iron.



In this Paper, Prof. W. H. Walker, of Boston, U.S.A., first describes the electrolytic theory of corrosion, according to which, when a strip of pure iron comes into contact with water, it sends into the water iron atoms in the form of positively charged ions. The free H ions in the water, however, plate out on the iron strip, leaving the free negative HO ions to balance the positive iron ions. A current thus flows from the iron to the solution, and back to the iron by means of the H ions. The addition of an acid increases the number of free H ions and hastens corrosion. The hydrogen forms an insulating film over the surface of the iron, however, and the action would cease were it not that in ordinary corrosion the oxygen in the water combines with this hydrogen. The free iron ions finally combine with the oxygen in the water, and are precipitated as rust. From the above theory, the author concludes that if differences of potential exist on the surface of the iron, they will accelerate corrosion, and that, as such differences of potential are caused by uneven distribution of impurities, iron with a small percentage of impurities will resist corrosion better. Corrosion can be reduced, according to this theory, by the addition to the water of a strong alkali which will decrease the number of free H ions. This has an important bearing on the question of the corrosion of iron embedded in concrete, as Portland cement liberates caustic lime (calcium hydrate), which should help the iron to resist corrosion. If water is allowed to percolate through the concrete, however, the calcium hydrate will be dissolved, and the beneficial action destroyed, so that the iron will rust. In order to reduce the corrosion of boiler shells and tubes, the author proposes to prevent the access of oxygen to the polarising film of hydrogen by removing the air from the feed-water, either by employing an open feed-water heater or a feed-water heater connected to the dry vacuum pumps of the condenser. Another method proposed is to draw the water through a box containing scrap iron, in which case the oxygen in the water is used up in corroding the scrap; or again, a solution of alkaline tannate added to the water would break up in the boiler, and would absorb the oxygen. The presence of another metal in the water, such as tin or copper, accelerates corrosion of the iron as it aids the oxidation of the hydrogen set free. This is why pin-holes in tinned iron become centres of corrosion. Magnetic oxide of iron or "mill-scale" is electro-negative to iron, and when iron or steel is protected by a coating of this, or of the black oxide of the Bower-Barf process, it prevents corrosion only so long as the coating is intact; when a portion of the iron is exposed, corrosion is all the more rapid owing to the oxidation of the hydrogen film.

In the ensuing discussion, Dr. A. S. CUSHMAN (U.S.A. Department of Agriculture), the author of one of the three Papers, entitled, "The Preservation of Iron and Steel," in which he had supported the above theory, described experiments made by Prof. Walker and himself, which conclusively proved the existence of electric currents flowing from and to different points on the surface of the iron or steel. Speaking with regard to protective paints, he pointed out that it was essential that any protective covering should be an insulator, as a conducting film on the surface would only accelerate the action. This explained why iron or steel painted hot resisted corrosion better than that painted cold, as in the former case the film of moisture was removed. The electrolytic theory had proved most valuable to paint manufacturers, and also to makers of tin plate and galvanised iron. Another speaker referred to the importance of cleaning the surface of metal before painting, and in closing the discussion the PRESIDENT called attention to the importance of the remarks in Prof. Walker's Paper with regard to the necessity of using dense waterproof concrete in reinforced concrete construction.

The first Paper to be read on Friday was that by Mr. W. Rodenhauser, on the application of the electric furnace to the manufacture of steel, which was followed by a long discussion. The only other Paper of electrical interest read on Friday was one by Dr. M. Ekenberg on the utilisation of peat.

The Electric Furnace in Steel Manufacture.

Mr. Rodenhauser's Paper dealt with the application of the electric furnace to steel manufacture, with particular reference to the Röchling-Rodenhauser furnace. Considering in the first place arc furnaces, the author compares the Stassano, Héroult, and Girod types, and concludes that in all three the charge is almost entirely heated by the arc only, the passage of the current through the metal in the two last patterns having little influence on the heat produced. The loss of energy in the electrodes, especially when water cooling is employed, is, he points out, considerable, namely, about 10 per cent., and the cost of maintenance of the electrodes is high. Turning to induction furnaces, the author describes briefly the Kjellin and Frick patterns, in which the metal, in a grooved annular hearth, forms the secondary of a transformer, the primary winding being wound on a core inside the annular hearth in the former, and above in the latter pattern. He asserts that the peculiar shape of the hearth in these furnaces, and the absence of side doors, prevent the removal or changing of slag, so that they can only be used for melting pure metals. The Röchling-Rodenhauser furnace, in which two or three grooves open out into an open hearth, and which was fully described in ELECTRICAL ENGINEERING of July 2nd, Vol. IV., page 17, is

PLAN OF RÖCHLING-RODENHAUSER THREE-PHASE FURNACE.

then dealt with. The author points out that slag can be removed from the side doors of this furnace, and that as the covers of the heating channels and hearth are not disturbed when the furnace is in operation, the heat loss is minimised. Besides the molten metal circuit, a distinct secondary winding is provided, and this is connected to cast-steel plates embedded in the refractory lining of the furnace, which conducts at high temperatures. By this means current is caused to pass through the metal in the central hearth. With regard to frequency, Mr. Rodenhauser points out that, whereas with a simple induction furnace for an 8-ton charge it is necessary to have a frequency of only 5 cycles per second in order that the power factor may not be less than 60 to 70 per cent., in the Röchling-Rodenhauser type the combination of induction and resistance furnace renders it possible to work a 16-ton furnace on a 25-cycle system with a high power factor. A plan of a three-phase furnace is given in the accompanying figure; *R*, *R*, *R* are the grooves in which the metal is heated, and *A* is the open hearth; the three cores and the primary windings, and the motor for tilting the furnace, are also shown. Tests made at Völklingen on a 3½-ton furnace of this pattern showed an efficiency of 97 per cent., and the load is fairly steady, as is evidenced by the fact that at the Röchling Iron and Steel Works a 2-ton furnace is working direct off the 400 volt, 50-cycle power circuit, taking from 200 to 250 kw. The furnaces in these works are supplied with molten metal from the basic Bessemer converters. The 2-ton furnace is used chiefly for the production of high-class tool steel, and several thousand tons of rails have been produced in the 8-ton furnace. On the question of the metallurgical conditions existing in the Röchling-Rodenhauser furnace, the author asserts that there is no electro-

Digitized by Google

lytic action, but that the passage of the alternating-current through the bath merely heats the metal. He also points out that owing to the good circulation, the metal obtained in this furnace is quite homogeneous.

The discussion was opened by Mr. A. WINDSOR RICHARDS, who stated that there was no doubt that electric refining for high-class steels and special alloy steels had come to stay, especially where cheap power was available, but that electric steel would have to become much cheaper to compete with ordinary steel. The rail steel mentioned by the author could be produced at a very much lower cost in the ordinary basic open hearth. He asked the author whether it was possible to produce such high temperatures in the induction furnace as in the Bessemer open hearth furnaces, and expressed the opinion that the high qualities of electric steel were not due so much to the absence of impurities, but to the absence of gases such as nitrogen and oxygen mixed with the steel.

Mr. G. M. GLEDHILL referred also to the high cost of electric smelting: his own firm had put down a recovery plant in connection with their smelting works, and they got from 80 to 90 lbs. of sulphate of ammonia from each ton of coal used to supply the gas for the furnaces. For this sulphate they obtained from £11 to £12 per ton, and with coal at 9 to 10 shillings per ton they got a very cheap fuel. He thought it would be a long while before the electric furnace would be able to compete with such plants.

Mr. O. FRICK, referring to the author's remarks on the "Frick" furnace, mentioned that an 8½ ton furnace of this type, taking 1,000 h.p., had been working at the Krupp Works at Esson since August last year, and had given such satisfactory results that the firm of Krupp had taken over his German patents. With regard to the removal of slag, his furnace had only one cover, which was made to rotate by means of a motor. There was an opening in this cover which enabled the whole of the bath to be easily inspected, and the slag to be skimmed off. He thought that the advantage in first cost obtained by employing a three-phase furnace in preference to a single-phase furnace was offset by the 25 to 30 per cent. more radiating surface in the former case. An electric furnace could not compete with the Bessemer process for smelting, but was useful owing to the very high temperatures obtainable, namely, up to 680° to 700° C. The efficiency of an electric furnace was very high, but the capital cost was two or three times that of ordinary smelting plant. Worked in combination with the Bessemer and Siemens Martin processes, however, the electric furnace was a commercial success.

Mr. A. HIORTH pointed out that in the three-phase furnace (see the accompanying figure) there was a distance of 20 inches between the primary coil and the molten metal secondary, which would result in heavy leakage and prevent the efficiency exceeding 70 per cent. The author claimed 97 per cent. efficiency for a 3½ ton furnace, however. He had designed a furnace in which the primary coil was divided into two halves, one half being arranged just over the molten metal secondary ring, and the other just below it. This furnace was designed for a 2½ ton charge, but it had successfully dealt with a 5-ton charge, taking 500 kw. with a power factor of 80 per cent.

Prof. MCWILLIAM (Sheffield University) doubted the author's statement that there was no electrochemical action taking place in the bath of the induction furnace. He thought that the extra cost of electric steel was justified by the higher quality obtained; one important company had decided to pay an extra price for rails of steel finished in the electric furnace, as they expected to get higher quality steel.

Prof. T. TURNER (Birmingham University) pointed out that there was no electrolytic action with alternating current, but that in direct-current arc furnaces the phosphides and sulphides of iron dissolved in the iron were possibly decomposed, and the metal actually purified by the passage of the current.

Mr. F. C. MOORWOOD hoped that the electric furnace would soon pass out of the hands of the electrical engineer, and into extended practical use, as he thought it would produce steel that could not be produced in any other way.

Mr. A. COOPER asked whether the author had had any experience in working blast furnace or mixer metal direct in the electric furnace; until this could be done, the electric furnace could not compete with the basic open-hearth furnace for rail making. Over 20,000 tons of rails of a composition similar to that of the author's electric steel rails, and capable of standing the same tests, had been produced in a works known to him.

Mr. T. ROWLANDS (American Electric Furnace Co.) remarked that it was necessary to use molten metal to start up the induction furnace; his company used rings of pure cast iron. They had melted steel containing 1·2 per cent. of carbon with a consumption of 440 kw.-hours per ton, and manganese steel at 600 kw.-hours per ton. A power factor as high as 82 per cent. had been obtained by them.

Mr. RODENHAUSER, in reply, remarked that the rail steel mentioned was only treated for ¾ hour in the electric furnace with a consumption of 100 kw.-hours per ton. In connection with Mr. Frick's remarks, he mentioned that the Frick furnace works at a frequency of only 5 cycles per second; the radiating surface of the Röchling-Rodenhauser furnace was not, he thought, any larger than that of the Frick furnace. With regard to the power factor, he knew of an 8-ton 600-kw. furnace which gave a power factor of from 85 to 90 per cent. The flat coil over the bath, suggested by Mr. Hiorth, would, he thought, make it very difficult to get slag out, and the coils would also require very efficient cooling.

The next Paper to be read was one by Dr. M. Ekenberg, entitled "Fuel from Peat."

The Utilisation of Peat.

This Paper, by Dr. M. Ekenberg, describes researches which were made with the object of finding a process for converting peat into fuel without air-drying, and which resulted in the discovery of the "Ekenberg" wet carbonising process, which is shortly to be tested commercially on a large scale in this country. Raw peat, even if taken from a well-drained bog, contains on an average 87 per cent. of water, and it has been usual to remove a portion of this by "air-drying" the peat, *i.e.*, by drying it by the sun's heat during the summer months. This process does not afford a regular supply, however, and necessitates the storage of large quantities of dried peat when used in conjunction with generating stations. The author discovered that the reason why the water could not be separated by mechanical pressure was because of the presence of a slimy hydrocellulose. This substance, however, is destroyed by heating in the presence of water at a temperature above 150° C. The "Ekenberg" process is based on this discovery, and consists in pumping the pulped raw peat through tubes heated to a temperature of about 200° C., and carbonising it in the presence of superheated water. The tubes are closed, and no evaporation of water takes place. After this treatment, the "wet-carbonised" peat is compressed to 50 atmospheres to press out the water, and the resulting cakes contain about the same amount of water as air-dried peat, namely, one-fourteenth to one-seventh of that of the raw peat. These cakes can be used direct in a gas producer plant, or can be further dried in a lignite briquetting plant. In the latter case, the resultant fuel has a calorific value of 11,000 B.Th.U. per lb., and, it is claimed, can be put on the market at the price of 6s. 8d. per ton, or, if the briquetting plant is worked with gas fuel from gas-producers with sulphate recovery, at the low price of 4s. per ton. Peat always contains nitrogen, and when utilised in a gas producer, this can be recovered in the form of ammonia sulphate. The author claims that with a gas engine generating plant supplied with gas obtained from wet-carbonised peat, power can be generated from a peat bog as cheaply as from a waterfall, and if the percentage of nitrogen is above 1·3, even cheaper.

In the discussion following this Paper, Mr. J. E. STEAD referred to the fact that a scheme for the utilisation of the peat bogs in the north of Ireland had to be abandoned owing to the fact that they would have had to depend on the sun for drying the peat. He asked whether the peat acted upon the iron tubes of the Ekenberg plant to any extent. In reply, Dr. Ekenberg said that some acid was formed during the heating of the peat, but that there was no more corrosion than could be covered by a 10 per cent. depreciation on the whole plant.

Several of the Papers were taken as read, and were not discussed. Among these was one by Messrs. P. Longmuir and T. Swinden on the Bristol recording pyrometer, an abstract of which is given below:—

The Bristol Recording Pyrometer.

Messrs. P. Longmuir and T. Swinden describe in this Paper the Bristol low resistance thermo-electric pyrometer, which is particularly suitable for ordinary shop use. Platinum and platinum-alloy thermo-elements have a comparatively short life in reducing atmospheres, and even in oxidising atmospheres such as those in annealing furnaces, and the cost of the thermo-couples becomes a serious item. In the Bristol pyrometer, an inexpensive couple is used, and the E.M.F. developed is so large that a Weston milli-voltmeter replaces the delicate high-resistance instruments used with platinum couples. The thermo-couple wires are insulated with asbestos cord, coated with carborundum paint, and protected by a metallic tube. The temperature can be read on a portable milli-voltmeter calibrated to read in degrees of temperature, and the recorder has a chart graduated in time and temperature, which is marked by the pointer of a milli-voltmeter at short intervals. To compensate for the error introduced by the variation in temperature of the cold junction, a "compensator" is put in the circuit near the cold junction; this comprises a platinum loop dipping in mercury in a small bulb. When the temperature rises, the mercury expands and short-circuits a portion of the loop, thus compensating for the diminution in the E.M.F. due to the rise in temperature of the cold junction. Comparative tests of a Bristol and a Roberts-Austen pyrometer, which show very close agreement, are described in the Paper.

CATALOGUES AND PAMPHLETS, &c., RECEIVED

[Readers applying to any of the under-mentioned firms for copies of the catalogues or pamphlets referred to are requested to mention "Electrical Engineering."]

JOINT BOXES.—A series of new leaflets from the British Insulated & Helsby Cables, Ltd. (Prescot), describe varieties of the Prescot joint box. One of these is an E.H.T. three-phase disconnecting branch box, suitable for colliery work and general use. The branch cable can be disconnected from the main cable, which is looped into the box. Other patterns include a three-way T-joint disconnecting box, and a small non-disconnecting three-way three-phase box. There are also two patterns of three-phase trifurcating boxes with porcelain insulators.

METAL FILAMENT LAMPS.—A new leaflet from the Armorduct Manufacturing Co. (Farringdon Avenue, E.C.), calling attention to the recent reductions in price of the "Gral" metal filament lamps, contains illustrations of a considerable variety of these lamps; ranging from miniature loop lamps from 1·2 volts and 0·5 c.p. to the 260 volt 100 c.p. lamp, and including various special types, such as miniature cap, tubular, and flame lamps.

FANS AND SMALL MOTORS.—A new catalogue from Simplex Conduits, Ltd. (113–117 Charing Cross Road, W.C.), deals with electric fans of the "Simplex Isaria" pattern, including a number of sizes of desk, bracket, porthole, cabin, and ceiling fans for both continuous and alternating currents. Motors of a similar type to those used for these fans, but over

SIMPLEX SEWING MACHINE MOTOR.

a larger range of output, are listed separately. One of these applied to the driving of a sewing machine is shown in the accompanying illustration. In this will be seen the combined arrangement of jockey-pulley, and brake adopted, which is worked by the treadle. The regulating rheostat can also be arranged to work from the treadle if desired.

ACCUMULATORS.—A handsome and comprehensive new catalogue of storage batteries is being issued by the Hart Accumulator Co., of Stratford. This is divided into sections conveniently accessible by means of a "thumb" index. The cells included comprise the ordinary lighting types in glass and lead-lined wood boxes, special 25-volt batteries for metal filament lamps, portable cells, traction cells, and various other patterns ranging from the large central-station cell to ignition cells for motor-cars. Attention is particularly drawn to the Hart patent sheet separator, and a full list of accessories, &c., is included.

MOTORS.—A folding leaflet from the Langdon Davies Motor Co. (Deverell Street, S.E.) contains a number of illustrations showing various applications of the company's continuous- and alternating-current motors.

MICROMETERS.—Messrs. Elliott Brothers, of 36 Leicester Square, have sent us copies of a pamphlet containing particulars of a new series of micrometers, for accurate workshop measurements, made entirely at their own works in Lewisham. The arrangement of the figures round the measuring head is very convenient. The standardisation of the screws has been done in connection with the National Physical Laboratory.

ELECTRIC VENTILATING FANS.—A new catalogue of electric fans has been issued by the Electric and Ordnance Accessories Co., Ltd., of Birmingham. A large variety of types are listed, including A.-C. and D.-C. desk fans, ceiling fans, porthole fans, railway saloon fans, &c., and all these are entirely of British manufacture. Attention may be particularly directed to a universal pattern of fan, in which the spherically-shaped motor carrying the fan is mounted on gimbals, so that it can be tilted in any direction, and the bracket placed on a table, or attached to the wall or ceiling. This particular pattern has been supplied in large numbers to the British Admiralty. Special care has been taken to ensure noiseless running.

TELEPHONE CABLES.—Messrs. Siemens Bros. and Co., Ltd. (Caxton House, Westminster), have produced a beautifully illustrated catalogue of their multiple telephone cables, which, besides containing a list of the various sizes and patterns that they are prepared to supply, contains other useful information relating to the manufacture of these cables. An account is given of the various processes that are gone through, from the covering of the conductor with paper in the longitudinal paper-covering machine, to the lead-covering and testing. This part of the book enters more into detail than is customary in such publications; it includes, for instance, a table of the lengths of lay employed in twinning the conductors of ordinary twin dry core cable, and also the width, thickness, and overlap of the metal tape used for "screened" conductors. Full-page illustrations show the various steps in manufacture, and the excellent coloured blocks of sections of cables are among the most perfect examples of three-colour printing that we have seen applied to technical work. For the guidance of telephone engineers, the specification of the "standard" telephone cable agreed upon for the purposes of comparative measurement by the British and American telephone administrations is given, and extracts are quoted from the agreement between the Post Office and National Telephone Co., stating the requisites of various lines in terms of this standard. The Dieselhort-Martin multiple twin system is also dealt with in some detail.

PROTECTED FLEXIBLE WIRES.—A leaflet is being issued by the Armorduct Manufacturing Co. describing a novelty which they have introduced in the shape of a patent rubber cord armoured flexible cable, to which the misleading name of "Gutta-flex" has been given. This is specially intended for portable appliances, such as hand lamps, radiators, electrically worked tools, &c. The conductors are insulated in the usual way with pure and vulcanised rubber, the pair is made circular with a worming of jute covered with rubber-proofed tape, a sheathing of vulcanised rubber is next applied, and over this is laid a braiding of a patent rubber cord, which is practically a cord core surrounded tubularly by a layer of rubber. The whole is then vulcanised together. It is claimed that this armouring compares in strength with some patterns of metal armouring and, on account of its resiliency, is much less susceptible to mechanical damage, that it possesses great durability, and, on account of its high insulating properties, secures safety from certain electrical risks. The company have sent us a sample of the cable from which its extreme flexibility as well as its neat appearance is evident. The same leaflet calls attention to a special flame-proof cable covered with a chemically treated braiding.

FITTINGS FOR METAL FILAMENT LAMPS.—A leaflet from the Armorduct Manufacturing Co. describes a series of lanterns for high candle metal filament lamps, which can be substituted with advantage for small arc lamps. On the same leaflet is illustrated a neat leaf fitting known as a lamp-holder husk for attaching to the holder and hiding the cap of metal filament lamp bulbs. These are very effective with frosted bulbs of elongated high-voltage metal filament lamps.

ROENTGEN RAYS LOCALISATION APPARATUS.—A pamphlet from Messrs. Siemens Brothers & Co., Ltd., of Caxton House, Westminster, describes an instrument for localising foreign bodies by means of Roentgen rays, known as the stereometer. This is an optical apparatus whereby accurate measurements can be made by viewing a pair of stereoscopic radiographs. It is claimed that this apparatus has the great advantage that it does optically what all previous types of localisers have done with cross-threads, &c., whilst it is more accurate than anything that has previously been designed for the purpose in question, and is constructed with the precision of a microscope. It is stated that, with the stereometer, foreign bodies, even in the eye, can be localised with great accuracy. The instrument is portable, and can be employed by anybody, whether they have had experience or not in stereoscopic radiography.

INSTRUMENT TRANSFORMERS.—A pamphlet from Messrs. Siemens Brothers & Co., Ltd., of Caxton House, Westminster, contains a description of several patterns of current and pressure transformers, including laboratory and portable transformers in the several ratios.

FLAME ARC LAMPS.—The Abbey Electric Co., of 17 Victoria Street, Westminster, have issued a leaflet containing a price list relating to the Abbey Flame Arc Lamp, which was fully described and illustrated in ELECTRICAL ENGINEERING, Vol. IV., Manchester Exhibition Supplement, page 46.

KNIFE SWITCHES.—A new list is to hand from the Electrical Company which deals with a considerable variety of knife and other quick-break switches, including the more ordinary lever forms, and also switches for mounting behind the board and actuated by handwheels or levers in front.

NEW ELECTRIC COOKING OUTFIT

THE latest development in heating and cooking apparatus is a very neat and handy cooking outfit, which has been put on the market by the General Electric Co., of 71 Queen Victoria Street, London, to meet the demand for a cheap and efficient outfit suitable for small flats and similar dwellings where the cleanliness and convenience of an electrical apparatus, with its freedom from objectionable fumes, may almost be said to be essential to comfort.

This outfit, which is illustrated in the accompanying figure, comprises an oven with three open coil heaters in the bottom, and two hot-plates of the ordinary pattern sunk into the top. A kettle, saucepan, steamer, and frying-pan of suitable dimensions to fit into the openings in the plate above the hot-plates are also provided. The oven itself is constructed of sheet steel and is double cased, the space between the two sheets being packed with asbestos lagging to minimise the radiation of heat. A special feature is the fall-down door, with chains to hold it horizontal when open, so that it can be used to rest dishes upon. The inside cooking space is 1 ft. 2 in. high by 1 ft. 1 in. wide by 1 ft. 3 in. deep, and is divided into compartments by two or more shelves. The heating coils consist of resistance wire helices wound over grooved china bobbins, and each consumes 500 watts. With all three coils switched on, the oven is raised to cooking temperature in from 15 to 20 minutes, and when this temperature is reached, two of the coils are switched off, as one suffices to maintain it. Thus the oven consumes 1,500 watts for from 15 to 20 minutes, and then 500 until the cooking is completed. The oven retains its heat for a considerable period after switching off, however.

THE NEW G.E.C. OVEN.

There are four switches attached to the oven; one of these controls two of the heating coils, and another the third. The remaining two switches are in the hot-plate circuits. One hot-plate takes 600 watts, and is for boiling water rapidly, while the other takes 400 and is for keeping warm or simmering. The former hot-plate is also used for frying. If all the heaters are on simultaneously, therefore, the consumption is 2,500 watts or 2½ units per hour, but the three coils need never be on for longer than 25 minutes, as explained above. The outfit is listed at £7 15s., complete.

Tramway Feeder Troubles in Manchester.—In an article under this heading last week, we referred to an interruption in the tramway service occasioned by some trouble on the feeders, and stated that the tramcars on the route in question were running again in a few hours. We are now informed that, as a matter of fact, the alarm was received at 9.50 p.m.; the repair wagon attended immediately, travelling over a mile to the spot, and cleared away the fault so expeditiously that cars were running again at 10.5 p.m.

"The Electron."—The April issue of the magazine conducted by the employés of Siemens Brothers' Dynamo Works, opens with a portrait of Dr. M. Kloss, chief of the Technical Department at Stafford. A portion of a Paper by Mr. C. A. Ablett on rolling mills is published, and also the second part of an interesting article by Mr. J. K. Catterson-Smith, on "Engineering and the Gyrostat." Among the smaller articles is one by Mr. J. C. Wilson, describing a weird and wonderful current generator, depending for its action on combined mechanical and electrolytic considerations. The last but not the least interesting of the articles is an illustrated account of the famous old cable ship, the *Faraday*, and her work in various parts of the world, where, since her construction in 1873, she has laid upwards of 31,000 nautical miles of cable.

The "Central."—The April number of the "Central," the journal of the Old Students' Association of the Central Technical College, Kensington, contains a most interesting and excellently illustrated article on the design of high masonry dams. The history of the development of the design of such dams is traced in some detail, and, in conclusion, some experiments carried out by the authors, Messrs. W. Gore and J. S. Wilson, on india-rubber models, are described. The other special articles are "Some Notes on Reinforced Concrete," by O. Faber; "The Control of Combustion," by W. N. Y. King; and "Impressions of an Eastern Railway," by R. L. Griffin. Mr. C. le Maistre also contributes an article on the Electrotechnical Commission. The number concludes with the usual "Old Student Notes," and reviews of a few recent technical books.

AN AUTOMATIC TRANSFORMER SWITCH

A NEW piece of apparatus has been brought out by Messrs. Morris & Lister, of Coventry, for the purpose of avoiding the no-load losses of small transformers so widely used in metal filament lamp installations. The switch is known as the "Bruston" transformer switch, and its object is to close the primary circuit as soon as the first lamp is switched on, and to break the circuit when the last lamp is switched off, and it has been so designed as to be practically independent of the size of the lamp switched on or off, and to be easily held on by the current taken by the smallest lamp in use. As an example of the economy that can be obtained by its use, it may be mentioned that with a 500 watt transformer with a no-load loss of 14 watts in use for an average period of 3½ hours, an annual saving of £2 3s. 9d. can be obtained with current at 5d. per unit. The switch is contained in a neat cast-iron case, and as will be seen requires a battery of 4 Leclanché or dry cells to work it. The operation of the switch will be clear from the diagram (which shows the internal

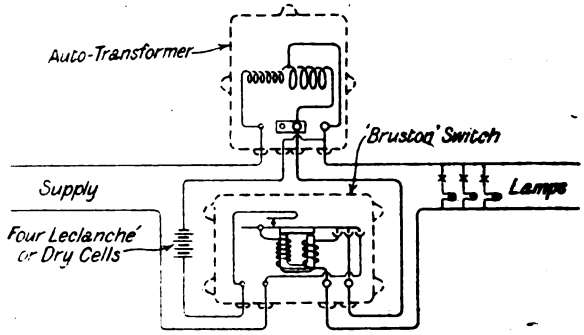

DIAGRAM OF CONNECTIONS.

connections as well as the external wiring connections). When the first lamp is switched on a circuit is closed through the battery, a relay coil and the lamp itself. The relay coil operates the switch, putting the transformer on to the mains. The movement of the switch breaks the small battery circuit. As soon as the switch is closed the lamp takes its normal current, which, passing through the main series coil, is sufficient to hold in the switch. When the last lamp on circuit is switched out, the automatic switch operates under the action of a spring.

In an installation where one or two lamps are required to run continuously, it will pay to use carbon lamps, and wire them directly to the supply, connecting the remainder to the secondary of an auto-transformer, used in conjunction with the "Bruston" switch.

Institution of Electrical Engineers.—The following were elected at the meeting on Thursday:—*Members:* G. L. Andrews, J. C. Taylor. *Associate Members:* C. L. Almers, W. R. Brash, H. Burkinshaw, J. H. Butters, W. E. Chappell, J. F. Clunas, J. Collinge, J. F. Crowley, B.A., J. J. Denton, A. Dimmack, H. J. Fisher, C. S. Hann, H. Hawkins, S. James, K. C. Knudsen, S. Mathews, T. R. J. Orr, H. J. Quilter, J. W. Speight. *Associates:* Lieut. M. Moreno, J. D. Morgan, R. Vincotte. *Students:* D. V. Crowe, F. G. Griffith, R. W. Manifold, F. H. Souden.

Newcastle Section of the Institution of Electrical Engineers.—The annual general meeting of the Section will be held next Monday. The following is the suggested list of Officers and Committee for the ensuing session. Members desirous of making further nominations must do so by Saturday next. *Chairman:* Prof. H. Stroud (Armstrong College, Newcastle); *Vice-Chairman and Hon. Sec.:* Mr. C. Faraday Proctor (The Edison & Swan United Electric Light Company); *Past Chairmen:* Mr. H. L. Riseley (Newcastle-on-Tyne Electric Supply Co.), Mr. James Pigg (North Eastern Railway), and Mr. A. L. E. Drummond (North Eastern Railway); *Committee:* Messrs. G. G. Stoney (Messrs. C. A. Parsons & Co.), G. Ralph (Messrs. J. H. Holmes & Co.), W. D. Hunter (Newcastle & District Electric Lighting Co.), C. S. Vesey Brown, A. S. Blackman (Borough Electrical Engineer, Sunderland), C. Turnbull (Borough Electrical Engineer, Tynemouth), A. H. Law (Messrs. C. A. Parsons & Co.), Prof. W. M. Thornton (Armstrong College, Newcastle), Messrs. J. A. Anderson, E. Fawssett, H. W. Clothier (Messrs. A. Reyrolle & Co.), H. Henderson, R. Rutherford, T. M. Clague, W. T. Dalton (Corporation Tramways, Newcastle), and G. S. Whitmore; *Hon. Treasurer:* Mr. W. A. Clatworthy (Messrs. J. H. Holmes & Co.).

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published May 13th, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

9,099/08. **Tramcar Trolley Wheel.** A. WERMANN. The trolley wheel is constructed like a double four-armed star, which revolves round a horizontal axle in the fork. The arms are connected by cross pieces half way along their length, and two of these rub against the contact wire at a time. The long arms prevent the trolley from running off the wire, and when any obstacle, such as a span-wire, is met, the star merely makes a quarter of a turn, the wire or other obstacle being passed between the two arms of the star. Three claims, three figures.

11,547/08. **Third Rail Protection.** C. H. MERZ and S. G. REDMAN. The conductor-rail is rolled in a modified I section, and the current is collected from the under surface of the head of the rail, which is of a much heavier section than the base or foot. The rail is attached at intervals to a base-plank supported on porcelain insulators, and further wooden planks are fixed on the top and on one side of the rail. The upper plank extends over the head of the rail and has a strip of wood along its edge. Five claims, three figures.

12,923/08. **Electromagnetic Operation of Tramway Points.** J. P. TIERNEY and J. MALONE. In the apparatus described, only one electromagnet is used. This actuates the point tongue through mechanism so constructed that after each movement of the point tongue the electromagnet is caused to swing into such a position as to operate the point tongue in the opposite direction when re-energised. Five claims, nine figures.

14,656/08. **Wiring Conduit.** G. EVANS. In order to secure electrical and mechanical continuity in unscrewed metallic conduit, a lug is provided on the end of the tube where it enters a socket, and this enters a slot formed between the socket and a collar or ring. The latter is provided with a screw for tightening up. Four claims, six figures.

16,151/08. **Arc-lamp Mechanism.** THE JANDUS ARC LAMP & ELECTRIC CO., LTD., and A. D. JONES. A lamp mechanism for vertically arranged carbons is described, in which two iron cores controlled by shunt and series solenoids in the usual manner are supported by a rocking lever pivoted near its centre. The upper carbon is supported by a clutch, and connected by links to one end of the rocking lever. The entire weight of the mechanism is thus supported at the fulcrum of the lever, which, according to this invention, is provided with ball bearings. This, it is claimed, will ensure close regulation, and steady burning of the lamp. Two claims, three figures.

27,991/08. **Lamp Fitting.** J. S. HIGHFIELD. This comprises a circular base-board, which is fixed to the ceiling, and a metallic casing terminating in a flanged opening, to which a glass globe is fitted. The whole is constructed practically air-tight, so as to exclude dust. Supported from resilient arms is a metal reflecting plate, to which are attached the lamp sockets. The resilient arms absorb vibrations transmitted from the floor above, and the reflecting plate, which fits loosely in the casing, acts as a damper to any vibrations. The casing is splayed out to collect the dust from the rising air currents, which would otherwise be deposited on the ceiling all round the lamp fitting. Four claims, four figures.

7,198/09. **Measuring Instruments.** M. FRANCOIS. In instruments with two or more different ranges obtained by varying the value of the shunt or series resistance or by any other means, it is proposed to have a separate scale for each range. The proper scale is moved into position under the opening in the dial and exposed to view by the action of the commutator or other device used to change the connections. Two claims, two figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

Arc Lamps: CARPENTER and BANKS, 9,222/08; JONES, 9,241/08.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: STRATTON and CLAPEMONT [Cable connectors] 9,323/08; COOPER [Equalising devices for A.C. circuits] 18,330/08.

Dynamos, Motors, and Transformers: AKT.-GES. BROWN, BOVERI, ET CIE. [Transformers] 9,146/08; BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*) [Motor-driven air compressors] 15,665/08; FERGUSON [Machines] 17,311/08; JOHNSEN and WALLEEN [Current collectors for D.-C. machines] 26,507/08.

Electrometallurgy and Electrochemistry: RAMSAY [Separation of oxides of nitrogen from air] 26,981/07; COWPER-COLES [Production of electrotypes] 9,695/08; HIGGINS [Recovery of tin from scrap] 25,068/08.

Ignition, Electric: R. BOSCH, 4,137/08; WYNNE [Interrupter] 9,156/08; SOC. ANON. MONTBARBON, 24,737/08.

Incandescent Lamps: SIEMENS & HALSKE AKT.-GES. [Increasing ductility of tungsten] 17,610/08; KÜZEL [Manufacture of filaments] 25,443/08.

Switchgear, Fuses, and Fittings: BENNETT [Automatic battery-charging switches] 24,047/08.

Telephony and Telegraphy: CUTMORE [Telephone mouthpiece cover] 9,581/08; GOOD [Disinfected telephone mouthpiece and earcap] 13,842/08.

Traction: BOULT [*Union Switch & Signal Co., U.S.A.*) [Automatic control of speed of trains] 12,176/08; BRUCE and COUTTS [Tramcar life-guard] 16,712/08; TIERNEY and MALONE [Point-shifting] 18,822/08; PETERSEN [Elevated suspension railway] 21,826/08; CURRAN and KELLY [Locking hook for trolleys] 23,002/08; SANDOZ-SUTTER [Cleaning tramway-rails] 24,346/08; BUSSE [Welding rail-joints] 1,099/09; SIEMENS BROS. & CO., and FERREIRA [Railway points] 4,595/09.

Miscellaneous: KNIGHT [Electric percussion tools] 8,930/08; BALSILLIE [High-frequency current generator] 8,972/08; MARSTON and POPE [Time alarm] 9,211/08; GILES [Clocks] 9,229/08; JUSTICE (*Deutsche Gasglulicht Akt.-Ges.*) [Miners' lamps] 9,654/08; WAYGOOD & CO. and CAREY [Cranes] 18,863/08; COOPER (*Boelling*) [Cooking apparatus] 21,494/08; HARTMANN & BRAUN AKT.-GES. [Resonance apparatus] 27,890/08; PEUKERT [Production of high-frequency oscillations] 4,762/09; STEINERT and STEIN [Electromagnetic separators] 6,267/09.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

TIRRILL [Voltage regulator] 28,190/08; DRAULT [Interrupter for A.-C. currents] 9,502/09; HORN [Voltmeters] 10,003/09.

Amendment Made

14,510/08. **Tramway Rails.** J. H. BRIGGS. This specification has been amended. A brief abstract and a statement as to the amendment required were given in ELECTRICAL ENGINEERING of April 1st, 1909, p. 311.

Opposition to Grant of Patents

12,139/07. **Manufacture of Metal Filaments.** F. J. PLANCHON. A patent has been granted on this application, in spite of opposition. It describes a process in which an alkaline solution of tungstic or molybdic acid is mixed with an aqueous or alkaline solution of an albuminoid substance, as gelatine or casein. The mixture is poured into dilute hydrochloric acid, and a precipitate appears, which is a compound of the tungstic or molybdic acid and the albuminoid substance. This is mixed with water to form a plastic mass, which is squirted into filaments. These are reduced to purely metallic filaments in a vacuum or inert gas by raising to a high temperature by means of an electric current. Filaments prepared in this way are stated to be very regular as regards dimensions and resistance.

9,288/08. **Battery Meters.** H. ARON. In consequence of opposition, the grant of a patent on this application, which describes battery meters with dials to indicate the maximum rates of charge and discharge as well as the total input and output, has been refused.

Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

Arc Lamps: W. R. RIDINGS [Magazine arc lamp] 2,277/03.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: B. G. LAMME [Pressure regulation on transformer distributing systems] 15,066/99.

Dynamos, Motors, and Transformers: BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*) [Reversing A.-C. repulsion motors] 2,452/04.

Electrometallurgy and Electrochemistry: H. H. LAKE (*G. Ramboldini*) [Electrolytic cells] 2,376/02.

Instruments and Meters: W. BASTRAM and H. C. HODGES [Prepayment meter] 2,224/96; R. D. MERSHON [Voltmeter connections for A.-C. circuits] 14,908/99.

Telephony and Telegraphy: A. MUIRHEAD [Siphon recorder relay] 2,310/02; J. T. ARMSTRONG and A. ORLING [Electro-capillary relays and coherers] 2,053/03, 2,053A/03, and 2,066/04.

Traction: S. P. THOMPSON and M. WALKER [Surface-contact tramway system] 1,765/99.

Miscellaneous: J. C. VICKERY [Alarm-bell attachment to bag or box handle] 2,465/04.

RAWTENSTALL CORPORATION TRAMWAYS AND LIGHTING

A New Arrangement at Feeding Points

On Saturday last the Rawtenstall tramways were opened for public service, thus completing another link of the system which will connect up the towns of Blackburn, Accrington, Haslingden, Rawtenstall, and Bacup. The Haslingden tramways were described in Electrical Engineering of September 10th, Vol. IV., page 382. That portion of the system in and around Rawtenstall, comprising some six miles of reconstructed track, and an extension one and a half miles long, was opened on Saturday, and in a few weeks' time the lines in Bacup, comprising about two miles of reconstructed track, will be opened, thus enabling direct communication by tramway between that town and Burnley.

The Rawtenstall Corporation obtained a Provisional Order as long ago as 1899, but it has only now been put into effect. In 1904 arrangements were practically concluded with the Lancashire Electric Power Co. for a supply in bulk, and a loan for sub-station machinery and mains was actually sanctioned, but in 1906 this scheme was abandoned as a result of the decision of the Council to purchase the tramways in the district and to erect their own generating station for supplying current for both purposes. Parliamentary powers were obtained in 1907, and subsequently negotiations were concluded for the supply of power to the Accrington tramways, and an agreement was arrived at between the Corporations of Bacup and Rawtenstall by which the latter Corporation will work the section in Bacup on leasing terms for a period of thirty years, at the end of which period that section will be taken over by the Bacup Corporation. Finally, the Rossendale Valley Tramways Co.'s steam tramway lines were also purchased, and they have been included in the general scheme.

The Rawtenstall power station is situated about a mile from the centre of Rawtenstall, in the direction of Bacup, on land adjoining the River Irwell, and supplies power for the tramways at 550 volts; a general lighting supply is given at 2 × 230 volts direct-current, and two outlying districts are supplied with three-phase alternating-current at 3,000 volts, which is distributed on the four-wire three-phase system at 230 volts. This latter supply is obtained by means of an inverted rotary converter, as the anticipated load was not large enough to justify the installation of an alternating-current generating set. Two 100-kw. Westinghouse rotary converters are employed, arranged on a common bedplate with a clutch, so that one can be driven by the other if necessary. Current for the alternating-current supply is generated on the A.C. side of the one or both converters at 350 volts, 50 cycles, and stepped-up by trans-

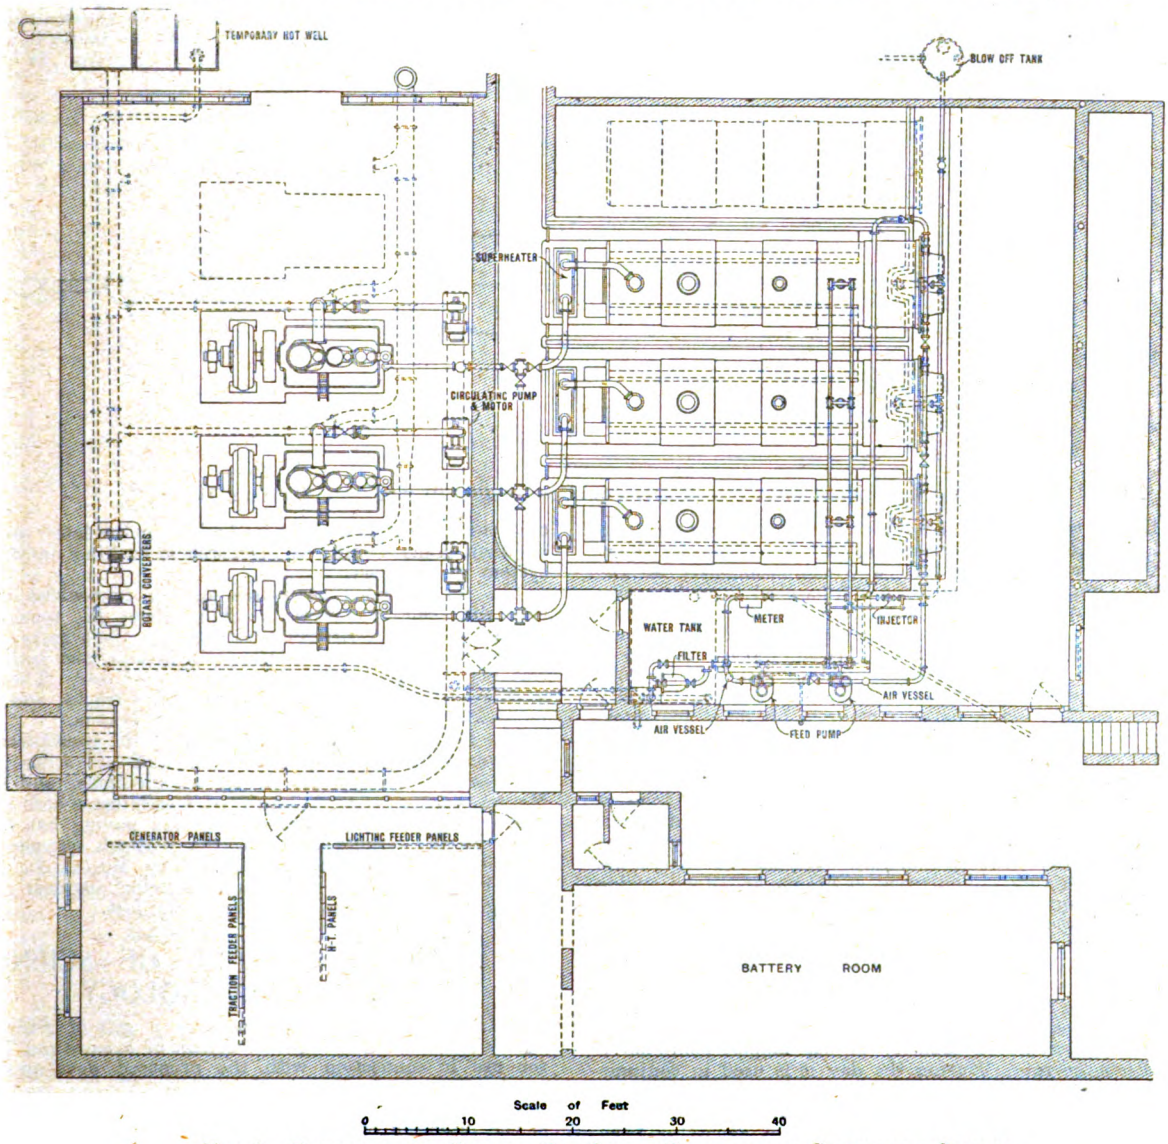

Fig. 1.—Plan showing General Lay-Out of Rawtenstall Generating Station.

Digitized by Google

formers to the transmission pressure of 3,000 volts. The converters can be run separately, or, when coupled together, can be used as a motor-generator set, in which case the generating machine can supply both A.C. and D.C. current. At night time one converter is connected to the battery on the D.C. side, and thus both the A.C. and the D.C. night lighting loads are supplied from the battery.

An interesting point in connection with this latter arrangement is that no balancer is required, as the neutral wire of the three-wire D.C. supply is connected to the neutral point of the three-phase alternating current system. The out-of-balance current is then taken care of by the rotary-converter.

The power station is a brick and stone building with an 180-ft. chimney. The general lay-out of the station can be seen from the plan of Fig. 1. There are three 30 ft. by 8 ft. Yates and Thom Lancashire boilers, working at a pressure of 180 lbs. per sq. in. Bennis automatic stokers with compressed air furnaces are fitted, and each boiler has a McPhail and Simpson superheater. Other auxiliaries include a Green economiser of 192 tubes, with scrapers operated by a 2-h.p. electric motor; two vertical-type compound steam feed-pumps, supplied by Messrs. J. P. Hall & Co., each with a capacity of 3,000 gallons per hour, which draw water from the River Irwell. There is also a Holden & Brooke injector capable of dealing with 2,000 gallons per hour. The steam piping is arranged so that each boiler supplies one engine, but a by-pass main is provided for interconnecting the units. Coal is delivered from carts into bunkers along the front of the boilers, and about 25 tons can be stored.

The three generating sets installed consist of three-crank enclosed triple-expansion engines of Messrs. Browett, Lindley & Co.'s make, coupled to E.C.C. six-pole compound-wound generators fitted with commutating poles. The normal output of each machine is 277 kw., and the pressure can be varied between 475 and 560 volts. The speed is 400 r.p.m. Each engine is fitted with a Korting ejector condenser, and electrically-driven Rees Roturbo circulating pumps are employed. The position of the two Westinghouse rotary converters is indicated in the plan in Fig. 1. There is also an automatic reversible booster of the Lancashire Dynamo & Motor Co.'s make, and two Crompton boosters for the traction feeders. An E.C.C. balancer for the lighting load is also installed. The battery consists of 240 D.P. cells, and has a capacity of 560 ampere-hours on a ten-hour discharge rate. During the day it is used in conjunction with the automatic booster on the traction system, the day lighting load being supplied from the D.C. side of one of the converters, which is driven as a double-current generator from the D.C. bus-bars, as explained above. At night the battery supplies both the lighting loads.

The low-tension switchboards for both tramway and lighting were supplied by Messrs. Whipp & Bourne, and have Everett, Edgcumbe instruments; the high-tension A.C. board was supplied by the British Thomson-Houston Co.

The total length of the tramway track in Rawtenstall and Bacup is over 8 miles, and there are numerous steep gradients; the steepest is 1 in 15, for a length of 15 chains. The gauge of the track is 4 ft., and the rails, weighing 100 lbs. per yard, are in 60-ft. lengths. Fishplates are used only at points and crossings; all the other joints in the track have been welded by the Thermit process. These latter joints are not bonded, but solid copper bonds are employed for the joints at points and crossings. The overhead equipment has been carried out by the British Insulated and Helsby Cables, Ltd., on the span-wire system, no centre poles being employed. Bracket-arms are used in one or two cases, and a few rosettes are employed. The grooved trolley wire is of hard-drawn copper wire of No. 000 S.W.G. section, and the earthed guard wires are of No. 8 S.W.G. galvanised steel. The poles are constructed in one piece, and are spaced about 40 yards apart. Four-line traction feeders are run out from the station, and are tapped into section boxes at half-mile intervals. There are two return feeders.

The arrangement at the feeding points, which is shown in Fig. 2, obviates the running of unsightly feeder cables along the span wires. In this sketch *A* is the span wire, *B*, *B*, are the section insulators in the two trolley wires, *C*, *C*, the ears, and *D*, *D*, are lengths of trolley wire carried from the ears to the ends of the feeders, which are brought up to the heads of the poles only.

The feeders are paper-insulated lead-covered cables, and are drawn into 3-in. stoneware conduits. There are thirteen feeding points in Rawtenstall and four in Bacup, and each section box contains the necessary switchgear, lightning arresters, &c., and a telephone set. The section insulators on gradients are so constructed that the gap is temporarily short-circuited when the trolley wheel is running over it, and this prevents an interruption of current when the cars pass up or down. It is important that the circuit should not be broken in the latter case, as well as when going uphill, as regenerative braking on the Raworth system is employed.

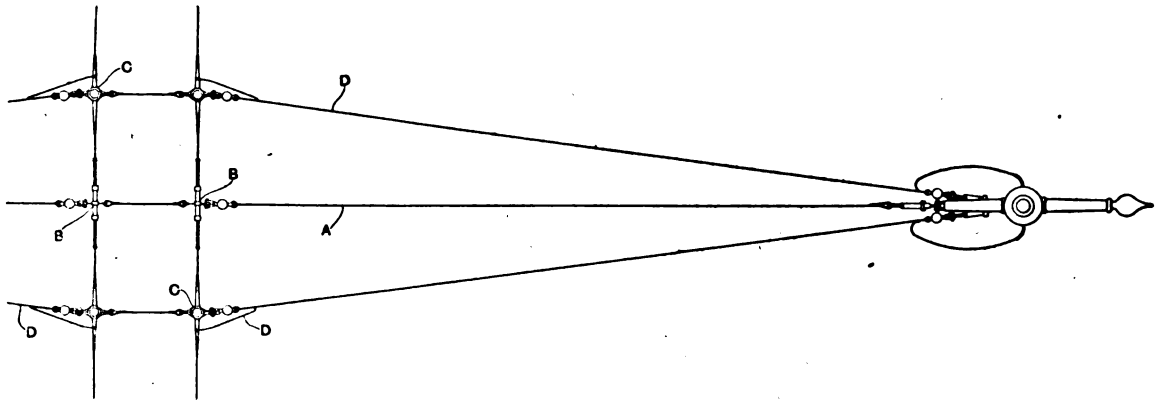

FIG. 2.—SKETCH SHOWING METHOD OF CONNECTING FEEDERS TO TROLLEY WIRE.

The rolling stock comprises sixteen four-wheel double-deck cars with canopy covers, weighing about 12½ tons each. The motors are of the British Westinghouse Co.'s make, wound for regenerative control on the Raworth system, and each of 42-h.p. capacity. There are two motors on each car. The depôt has accommodation for seventeen cars on five tracks, and is situated in Rawtenstall, near the centre of the system.

The reconstruction and extensions of the permanent way, the electrical equipment, power-house, and all other work, has been carried out to the plans, specifications, and designs of Messrs. Lacey, Sillar, & Leigh, of Westminster and Manchester. The laying of the permanent way and paving has been supervised by Mr. James Johnson, the borough engineer, and the electrical work has been supervised by Mr. C. L. E. Stewart since his appointment as borough electrical engineer and general manager of the tramways in February last.

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

THE Goldsmiths' Co. have made a gift of £50,000 to the Governors of the Imperial College of Science and Technology, for use in connection with the proposed development of the Engineering Department. The letter offering the gift stated that the Goldsmiths' Co. have learned with satisfaction that it is the intention of the governing body of the Imperial College of Science and Technology to extend the department of engineering, at present housed in the Central Technical College of the City and Guilds Institute, by constructing new lecture rooms, laboratories, and workshops, thus forming an extensive addition to the building of the Central Technical College; and, further, that the whole of the engineering department of the Imperial College will be called "The City and Guilds College." Under these circumstances, the Goldsmiths' Co. desire to make a substantial contribution towards the cost of the new building, and they will be prepared to provide the sum of £50,000 for this purpose, payable as to £10,000 on the day whereon the contract for the work shall be signed, and as to the remainder of the grant by instalments spread over a period of not less than three years. This gift is made by the company in their sole corporate capacity, irrespective of their support to the City and Guilds Institute, to which body they have been the largest contributors, and their subscriptions to which they do not propose to curtail. The gift has been accepted by the Governors of the College, and the question of giving the company separate representation on the proposed delegacy, which it is intended to appoint to administer the engineering department, is under consideration.

LINKING UP THE LONDON ELECTRICITY WORKS

Joint Committee of Borough Councils and Companies formed

THE London Borough Councils owning electricity undertakings wish to lose no time in taking advantage of the provisions of the London Electric Supply Act, 1908, which for the first time in the history of the electrical industry legalised "association" between various electric supply authorities. Under the Electric Lighting Acts, an authority was not even legally permitted to give a supply to another in case of breakdown, although it is common knowledge that the strict letter of the law in this respect has not always been complied with. Under the London Electric Supply Act of 1908, however, both local authorities and companies are allowed to link up their undertakings in the widest possible sense, even to the extent of one authority handing over the working of its generating station or distributing system to another, always, of course, with the sanction of the Board of Trade.

Almost immediately the London Electric Supply Act of 1908 received Royal assent, the London Borough Councils carefully considered the whole position—as a matter of fact, the electrical undertakings of the Poplar and Stepney Councils were then actually connected up for emergency supply—and the Associated Municipal Electrical Engineers (Greater London) appointed a committee of investigation to formulate some proposals. This committee included the following Borough electrical engineers: S. Baynes (St. Pancras), H. W. Bowden (Poplar), E. Calvert (Finchley), A. C. Cramb (Croydon), A. J. Fuller (Fulham), A. Gay (Islington), C. Newton Russell (Shoreditch), A. H. Seabrook (West Ham), N. Staniland (Hornsey), and W. C. P. Tapper (Stepney).

This committee presented a report, the details of which, however, it is not thought expedient to have published at the present moment. This has been approved by the Associated Municipal Electrical Engineers (Greater London), and contains a recommendation that there should be uniformity in the systems of linking up, that a pressure of 10,000 volt three-phase at 50 periods should be employed for the ring mains, and that there should be an agreed unit of converting plant throughout, viz., 500 kw., which could be used singly or two or more in parallel in each case, as circumstances might demand. The initial object of the linking up would be to deter the owners of the smaller generating stations from adding to their plant. This report also points out that it would not pay to lay the very long length of mains necessary to connect up those municipal undertakings in the far west of London, such as Hammersmith, and Fulham, for instance, and that obviously the most reasonable arrangement would be to have some joint scheme for linking up with the companies throughout the Greater London area.

Consequently the Associated Municipal Electrical Engineers (Greater London) put this proposition before a conference of local authorities, when it was agreed to call a joint conference of local authorities and companies to discuss it. This latter conference was held on Wednesday last week, May 12th, when nine companies and twelve local authorities were represented, and it was resolved that it was advisable, providing a suitable scheme could be formulated, that the powers conferred under the London Electric Supply Act, 1908, should be carried out jointly by the local authorities and companies. It was also resolved to appoint a Consultative Committee of twelve members, six representing the Borough Councils and six the companies, to draw up rules of procedure. The conference also decided to appoint joint secretaries, and Mr. H. B. Renwick (General Manager and Secretary County of London Electric Supply Co.) was appointed to represent the companies, and Dr. H. Mansfield Robinson (Town Clerk, Shoreditch) to represent the local authorities.

Action re Suction-gas Generating Plant.—Under this heading on page 409 of our issue of May 6th, we gave a report of the first two days' hearing of an action taken by Mr. C. A. Seebold, of Worthing Theatre Royal, against Messrs. Page & Miles, Ltd., contractors, to recover damages for alleged negligence in installing an electric lighting plant. The trial was concluded after a four days' hearing, in which expert evidence was given as to the condition of the plant, the general opinion being that it was well constructed and erected. Several witnesses gave evidence as to the difficulty of starting the engine, however. The judge has reserved judgment for a month.

PARLIAMENTARY INTELLIGENCE

PROGRESS OF ELECTRICAL BILLS.—The North and South Shields Electric Railway Bill has been withdrawn by the promoters owing to their inability to come to terms with the local authorities in the district on the question of guaranteeing the debenture interest on the capital of the proposed company.

The South Western and Isle of Wight Junction Railway was read a first time in the House of Commons on Thursday.

The Watford and Edgware Railway Bill is now unopposed.

The Oxford Electric Tramways Bill was passed by the Unopposed Committee of the House of Lords last week, the Oxford Corporation having withdrawn their opposition, since the modified agreement was come to with the National Electric Construction Co. for the construction of a combined conduit and overhead trolley system.

The North-East London Railway Bill was read a second time in the House of Commons on Monday.

The Electric Lighting Acts (Amendment) Bill was read the first time in the House of Commons on Monday.

The North Metropolitan Electric Power Supply Bill was read the third time in the House of Commons on Monday.

TORQUAY TRAMWAYS.—A few weeks ago, owing to the inability of the promoters of the Torquay Tramways Bill to obtain the consent of the Paignton Urban District Council to the extension of the tramways from Torquay into this district, the Standing Orders Committee of the House of Commons decided that the Bill could not proceed. The Examiners of Standing Orders in the House of Lords had previously allowed the Bill to proceed, for the reason that they felt the Paignton Council was withholding its consent unreasonably in order to secure terms from the company. Last week, however, in the House of Commons, Mr. J. Ellis, Chairman of the Standing Orders Committee, moved that the Bill be referred back to the Standing Orders Committee, as terms have been arranged between the parties. This has now been done, and the Bill is to be allowed to proceed for consideration by a Select Committee.

MUNICIPALITIES AND ELECTRIC WIRING.—In connection with the clause in the Electric Lighting Acts (Amendment) Bill, stipulating that municipalities may carry on electric wiring and fittings only through a contractor (ELECTRICAL ENGINEERING, May 13th, page 440), the Incorporated Municipal Electrical Association have been in communication with the municipalities throughout the country on this question in order to enlist their support in opposing this clause when the Bill comes up for consideration in the House of Commons.

WEST KENT ELECTRIC POWER BILL.—This Bill, which was passed by the unopposed Committee of the House of Lords on Tuesday, transfers to the West Kent Electric Power Co. certain powers of supplying in an area to the north of Northfleet, Kent, granted to the Kent Electric Power Co., in 1903, The Bill also provides for an agreement between the two companies and also agreements between the companies and local authorities.

GATESHEAD & DISTRICT TRAMWAYS BILL.—This Bill, which was passed by the unopposed Committee of the House of Lords on Monday, proposes the construction of three new short lengths of tramways, and the raising of additional capital to the extent of £15,000. Powers to adopt the trackless trolley system of traction are contained in the Bill.

SOUTHPORT, LYTHAM TRAMROAD (AMENDMENT) BILL.—The unopposed Committee of the House of Lords passed this Bill on Tuesday. It provides for the abandonment of the tramway scheme authorised a few years ago.

BAKER STREET & WATERLOO RAILWAY BILL.—The promoters of this Bill have withdrawn it. It applied for an extension of time for the compulsory acquisition of lands authorised in 1906, and for the completion of certain railway works. The most important part of the Bill, however, was the cancellation of an agreement between the company and the Westminster City Council for the construction of pedestrian subways at Trafalgar Square and the abandonment of the subways provided for. The acquisition of extra land for extensions at the Oxford Street station was also included in the Bill.

NORTH-WEST LONDON RAILWAY BILL REJECTED.—After a hearing lasting for two weeks, Mr. Compton Rickett's Committee of the House of Commons rejected this Bill on Friday. We gave the objects of the Bill on p. 441 of our last issue.

LONDON UNITED TRAMWAYS BILL REJECTED.—Lord Ludlow's Committee of the House of Lords, which commenced consideration of this Bill last week, rejected it on Friday. The London County Council has authority to purchase the short portions of the London United Tramways Co.'s system, which are within the London County boundary at Shepherd's Bush and Hammersmith, and has already given notice of its intention to do so, but the Bill proposed to postpone the period of purchase for a further ten years in the case of the Hammersmith line, and for fifteen years with regard to the Shepherd's Bush line. A much more important proposal, however, was the granting of compulsory reciprocal running powers over the lines

Digitized by Google

of the County Council and the company. Whilst, on the one hand, the Council strongly objected to the principle of being compelled to give running powers over any route, and especially over routes selected by the company, it was further pointed out to the Committee that the routes selected by the company on the Council's lines ran through densely populated districts, whereas the routes offered by the company on their lines were all in rural districts, where the number of passengers was comparatively small. The County Council expressed a willingness to discuss running powers with the company, and called several witnesses, including Mr. A. Baker, general manager of the Birmingham Corporation tramways, who stated that no difficulty had been experienced in Birmingham in arranging running powers with the various companies running outside the Birmingham boundary. The County Council further defended their existing right to purchase, but declared that they would be willing to make a reasonable arrangement with the company afterwards, in order to avoid running a shuttle service and a change at the county boundary.

LONDON COUNTY COUNCIL TRAMWAYS BILL.—A Committee of the House of Commons, presided over by Sir George Doughty, is now considering this Bill. The main objects of it are to extend the tramways from Gray's Inn Road along Farringdon Road to the City boundary at Charterhouse Street, to acquire the Highgate Hill cable tramway, and reconstruct it upon the conduit system, and to construct some additional lines in the South of London. The first portion of the Bill dealt with by the Committee was the extension along Farringdon Road, to which there has been considerable opposition by the costermongers, who have had their stalls along there for many years, and also by the Great Northern Railway Co., who have a goods depôt with a frontage extending along a considerable portion of that thoroughfare. On Tuesday, however, the Committee decided to pass this section of the Bill, providing the Council gave some assurance that there would be no unreasonable delay at the terminus. The object of this was to ensure that the tramways should not be the cause of anything in the nature of a block in the traffic.

CENTRAL LONDON RAILWAY BILL.—Sir Compton Rickett's Committee of the House of Commons commenced consideration of this Bill on Tuesday. It provides for the extension of the Central London Railway from the Bank to Liverpool Street, at an estimated cost of £300,000. A fuller report will be given in our next issue.

LOCAL NOTES

ASTON: *Electric Lighting Accounts.*—The past year's working of the electricity undertaking has resulted in a net profit of £2,951. This has enabled the Committee to discharge the deficit upon the undertaking, and to carry forward a credit balance of £244.

BARNSLEY: *Electricity Accounts.*—The result of the past year's working of the electricity undertaking has been a profit of £1,429, of which £1,000 has been granted to the relief of rates and £429 carried forward.

BECKENHAM: *Linking Up.*—With reference to the recent proposal of the Beckenham Council to arrange for a mutual supply of electricity in case of emergency with the South Metropolitan Electric Light & Power Co., the Board of Trade have reminded the Council that although the company is authorised to supply in Beckenham, the Beckenham Council have no powers to supply in the area of the company. When the present Electric Lighting Acts (Amendment) Bill becomes law, this disability will be removed.

BELFAST: *Charge for Tramway Current.*—Mr. Andrew Nance, the Tramways Manager, having complained that his department had been overcharged to the extent of £1,222 for electrical energy during the past year, a Sub-Committee has been appointed to inquire into the matter.

Electricity Accounts.—The accounts of the Electricity Department for 1908–1909 show a net profit of £9,270, to which is added £2,098 brought forward from the previous year. The General Purposes Fund is to be credited with £5,000, and depreciation with £6,368. The number of units sold for lighting was 2,055,935, an increase of 2·2 per cent., and for power 1,587,989 units, an increase of 8 per cent. during the year. The cost of production has been reduced by 11 per cent., partly due to the efficiency of the turbo-generating machinery, and partly to a reduction in the price of coal. The maximum load during the year was 6,309 kws.

BEXHILL: *Electricity Accounts.*—The accounts of the municipal electric lighting undertaking for the past year show a net profit of £536.

BIRMINGHAM: *Tramway Accounts.*—The net profits upon the municipal tramways for the past year amounts to £51,000, and it is proposed to allocate £29,000 to the relief of rates.

Electricity Accounts.—There is a surplus of £10,000 upon the electricity undertaking, which it is proposed to transfer to the relief of rates.

BRIGHOUSE: *Electricity Accounts.*—There is a loss of £482 upon the year's working of the municipal electricity undertaking. This, however, refers to the old generating plant, which is being replaced by a supply in bulk from the Yorkshire Electric Power Co.

BRIGHTON: *Charges for Power Supply.*—Mr. J. Christie, the Borough Electrical Engineer, has reported that there are several factories where the 1d. per unit rate, with restricted hour service, is too high to enable the Corporation to obtain this business. He therefore suggests that a special rebate should be given when the consumption exceeds 300 units per quarter per h.p. installed, varying from 2½ per cent. discount to 10 per cent. discount, when the supply exceeds 450 units per quarter per h.p. installed.

BURTON-ON-TRENT: *Tramway Accounts.*—The accounts of the Municipal Tramways Department for the year to March 31st show a total income of £15,109, compared with £15,921 of the previous year. The working expenses have increased from 5·85d. to 6·37d. per car mile. The number of passengers carried was 3,090,805, against 3,221,595 for the previous year. Compared with the second year of working, 1904-5, this shows a serious reduction of 786,482. After meeting capital charges and placing £1,000 to renewals fund, there is a deficit of £2,747, compared with £121 for the previous year. It may be noted that the revenue has borne the cost of fixing the Pringle emergency skid brake to all cars working on a steep gradient, in addition to altering the design of sanders from intermittent to continuous, and placing them so as to discharge close to the wheel instead of some three feet away.

CARDIFF: *Tramways.*—Mr. Arthur Ellis has asked for a free hand with regard to the working of the tramways undertaking, and, in a long statement which he has placed before the Corporation, makes it quite clear that he could not be held responsible for unremunerative routes, the fares upon which he had not recommended. If he were granted a free hand, and the result was not satisfactory, he would willingly stand aside. The Tramway Committee's recommendations to increase the fares upon certain routes, referred to in our last issue, have been adopted.

DARLINGTON: *Electric Lighting Accounts.*—The accounts of the Electricity Department for the year to March 31st show a gross profit of £9,483. The net profit, after meeting capital charges, is £1,933, and the Committee have handed over the sum of £2,000 to the relief of rates.

DUBLIN: *Charges for Electricity.*—At the last meeting of the Corporation a resolution was moved as follows: "That for the purpose of preventing the electric lighting undertaking from being carried on at a loss to the ratepayers, the Lighting Committee be and are hereby authorised to increase the charges by whatever sum they may find necessary, not exceeding ½d. per unit." On a division the motion was lost by 10 votes to 26.

GILLINGHAM: *Day Load.*—A special meeting of the Council was held on the 18th inst., to consider whether the supply to deal with the day load shall be taken from the Kent Power Co., or whether a Diesel oil-engine set shall be installed for this purpose. A deputation is to pay visits to Leatherhead and Guildford to see the Diesel engines at work there.

GRIMSBY: *Electric Lighting Accounts.*—The accounts of the Municipal Electric Lighting Department show a gross profit of £9,264, and, after meeting capital charges, the net profit is £3,184 compared with £2,442 in the previous year.

KEIGHLEY: *Electricity Accounts.*—Mr. J. M. Smyth, the Borough Electrical Engineer, has presented a report on the working of the electricity undertaking for nine months to March 31st, 1909. The receipts amount to £5,670, and the expenditure to £3,226. After meeting capital charges, &c., there is a balance of £30, against a deficit of £562 for the previous twelve months, and £1,495 for the year 1906–7.

LEEDS: *Electricity Accounts.*—The accounts of the Electricity Department for the year to March 31st show a gross profit of £67,738, and, after meeting interest and sinking fund charges, there is a net surplus of £8,248. Of this, £3,000 have been carried to reserve fund, and £5,248 transferred to relief of rates.

LEITH: *Tramway Extension Opened.*—The extension of the Leith tramway system to Granton was officially inspected on behalf of the Board of Trade last week, and subsequently opened to the public. The new line is about one mile in length, and consists of double track throughout, except for a few yards.

LONDON: *Hackney: Supply to Bethnal Green.*—The Electricity Committee report having instructed the Electrical Engineer to prepare a scheme for supplying the Borough of Bethnal Green with electrical energy.

St. Pancras: Borrowing from Reserve Fund.—The recent decision of the Council to borrow £12,000 from the electricity reserve fund for the purpose of capital expenditure upon the electrical undertaking has called forth a remonstrance from the London County Council. The Finance Committee of the Borough Council, however, state that this action is quite in order, and recommend the Council to adhere to their decision.

Stepney: Electricity Accounts.—The annual report of the electricity undertaking to March 31st last shows a gross profit of £18,185. As compared with last year the income increased by

Digitized by Google

£5,484, and the expenditure by £4,401. Although the expenditure had increased, the amount received per unit sold had decreased from 0·924d. to 0·92d. Deducting payment of capital charges, &c., there remains a balance of £1,808, which the Committee had decided should be dealt with by carrying £791 to next year's account, £100 to reserve account, the balance to be laid out in expenditure in the nature of capital.

Woolwich: Testing Stations.—In accordance with a notice received from the L.C.C., three testing stations are to be established at a cost of from £16 to £20 each. New tenders are to be invited for the pipework for the cooling pond at the Plumstead generating station.

NEWCASTLE: *Tramway Accounts.*—The accounts of the Corporation Tramways Department for the year to March 1st show a gross profit of £81,513, against £94,466 in the previous year, and after meeting interest on loans, rents, and depreciation on horses and rolling stock, there is a balance of £45,361 against £55,907. From this has been deducted £36,251 sinking fund charges, in addition to interest on unexpired horse tramway loans, and £7,557 transferred to reserve and renewals fund, bringing the latter up to £69,880.

NOTTINGHAM: *Electricity Department.*—The sum of £17,000 has been paid over by the Electricity Department in relief of rates, as the result of the past year's trading.

RHYL: *Oil Engine Generating Plant.*—A deputation has paid a visit to the works of the Birkdale Electric Supply Co. in order to inspect the Diesel oil engine set which is there. A report is to be submitted at the next meeting of the Electricity Committee.

SHIPLEY: *Electric Lighting Accounts.*—The accounts of the municipal electricity department for the year to March 31st show a net profit, after paying interest and sinking fund charges, of £151, thus reducing the debit balance to £732.

WALSALL: *Electricity Extensions.*—With reference to the recent decision not to proceed with the scheme of extensions recommended by the Electric Lighting Committee, the Corporation have now appointed a committee of six members not being members of the Electricity Committee, to co-operate with the Electricity Committee in reconsidering the proposed expenditure of £35,000.

WIGAN: *Electricity Accounts.*—Although there was a loss upon the Pemberton power house for the past year of £1,634, there was a profit of £3,106 in respect of the Wigan department, leaving a net profit on the two places of £1,472. For the previous year, the profit was only £804.

Tramway Accounts.—The accounts of the tramways department for the past year shows a loss of £3,941 against £5,611 for the previous year. The number of passengers carried was 12,039,250, against 11,867,950 in the previous year, the receipts per car mile being 11·66d. against 11·31d. The Chairman of the Tramways Committee points out that this latter result is only obtained by nine other Corporation undertakings in the United Kingdom.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

ABERDARE.—A Local Government Board inquiry was held on Tuesday into an application by the Council for sanction to borrow £17,000 for electric lighting installation.

ASHBY.—An electric lighting scheme has been placed before the Council, involving an expenditure of £15,000 if a certain portion of the district be dealt with, or £25,000 if the whole of the district is dealt with.

AUSTRALIA.—The City of Melbourne Corporation require tenders for the supply of, alternatively, one 1,000 kw., one 1,250 kw., and one 1,500 kw. direct-current generating set. Particulars from Messrs. McIlwraith, McEacharn & Co., Ltd., Billiter Square Buildings, London, and tenders to the Chairman of the Electric Supply Committee, Town Hall, Melbourne, by July 14th.

BELFAST.—The Board of Guardians proposes to apply to the Local Government Board for a loan of £4,800 for cables for the electric lighting of the Abbey Sanatorium.

BRIDLINGTON.—A Local Government Board inquiry was held last week into an application by the Council for sanction to borrow £5,000 for electric lighting purposes.

BURY.—Tenders are invited for the erection of an electricity works at Chamber Hall, Bury. Particulars from the Borough Engineer and Surveyor, and tenders by June 2nd.

CLEETHORPES.—A Local Government Board inquiry was held last week into an application by the Council for sanction to borrow £4,000 for electric lighting purposes. This amount is for preliminary work prior to the acquisition of the tramway company's power station at an estimated cost of £17,000. During the inquiry, Mr. H. R. Hooper expressed the opinion that the proposals with regard to the financial position placed before him were "beautifully vague."

CLECKHEATON.—The Council invite tenders for the supply and delivery of coal at the Electricity Works during the ensuing twelve months. Tenders to the Clerk by June 3rd.

CORK.—Tenders are invited by the County of Cork Joint Hospital Board for an electric lighting and boiler plant. Plans and specifications from the Engineer, Mr. R. Evans, 53 South Mall, Cork, and tenders to the Secretary by June 5th.

GRIMSBY.—Tenders are invited for two super-heaters for sterling boilers and the renewal of dripping bars in existing cooling-towers. (See advertisement this week.)

HEREFORD.—A Local Government Board inquiry was held on Tuesday into an application by the Council for sanction to borrow £8,000 for electric lighting purposes.

HORNSEY.—Tenders are invited for the supply of cables. Particulars from the Borough Electrical Engineer, and tenders to the Town Clerk by May 28th.

KEIGHLEY.—The Electricity Committee contemplate an expenditure of about £16,000 on additional mains, to meet the growing demands for power supply.

KILMARNOCK.—A loan of £430 is to be applied for in connection with the electricity undertaking.

LEEK.—Extensions of cable are to be carried out at an estimated cost of £360.

LLANDAFF AND DINAS POWIS.—The Rural District Council propose an expenditure of £2,960 upon an electric lighting scheme in the parish of Whitchurch.

LONDON: *Bermondsey.*—A loan of £5,262 is to be taken up from the London County Council for the purposes of the electrical undertaking.

MANCHESTER.—Tenders are invited for stores during the ensuing twelve months, including arc lamp carbons, dynamo brushes, &c. Particulars from the Secretary to the Electricity Department, and tenders by 29th inst.

MIDDLESBROUGH.—A Local Government Board inquiry was held last week into an application by the Council for sanction to borrow £10,000 for cables, &c.

PORTUGAL.—The municipal authorities of Coimbra have been authorised to contract a loan of about £20,000 for the establishment of an electric tramway service.

WATFORD.—A Local Government Board inquiry was held last week into an application by the Council to borrow £4,952 for electrical extensions.

Miscellaneous

AUSTRALIA.—The Deputy Postmaster-General at Melbourne invites tenders until September 14th for the supply and delivery at the Post Office, Hawthorn, Victoria, of eight sections of a common battery switchboard.

FINCHLEY.—A Local Government Board inquiry was held last week into an application by the Council for sanction to borrow £2,200 on a street lighting scheme. The estimates are as follows:—Fifty arc lamps, including cable fittings, £2,036; 34 extended bases to poles, £136; and contingencies, £28. The annual cost is estimated at £1,000, from which is deducted the cost of the present lighting, making the net extra annual cost £739. There was considerable opposition to this scheme, both by ratepayers and the gas company.

LONDON: *Poplar.*—Electric fans are required by the Board of Guardians. Particulars from the Clerk, 45 Upper North Street, Poplar, and tenders by May 26th.

NEW ZEALAND.—The Dunedin Harbour Board propose to erect electric cranes at an estimated cost of £1,800.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON: N.—School, Shelburne Road, Islington. (£10,739.) J. T. Bailey, architect, L.C.C. Education Committee, Victoria Embankment, E.C. Builders, E. Lawrence & Sons, Wharf Rd., City Rd.

N.W.—Laundry and handicraft centres on site adjoining Acland School, St. Pancras. T. J. Bailey, architect, L.C.C. Education Committee, Victoria Embankment, E.C.

S.E.—The London County Council require tenders for wiring the Oliver Goldsmith's Elementary School extension, Peckham Road, for electric lighting. Particulars from Spring Gardens, and tenders by May 26th.

Addition to G.P.O. Sorting Office, and erection of six houses, Halliwell Road, Brixton. Architects, Fasnacht & Beale, 17 Old Queen Street, S.W.

Addition to Eltham Cottage Hospital, Park Place, Eltham. Whistler & Warge, 80 High Street, Eltham.

Mission-room and gymnasium, Marine Street, Bermondsey. Architects, Gale, Gotch, & Leighton, 225 Long Lane, S.E.

S.W.—Hospital (£6,000), Wimbledon. M. G. M. Carver, Secretary, South Wimbledon & Merton Cottage Hospital.

Housewifery centre at Tooting Graveney School, Wandsworth. T. J. Bailey, architect, L.C.C. Education Committee, Victoria Embankment, E.C.

Digitized by Google

Skating rink and hall, East Hill, Fairfield. Builder, J. Watt, The Lodge, Bromley Road, Catford, S.E.

The London County Council invite tenders for wiring the County Secondary School, Putney, for electric lighting. Particulars from Spring Gardens, and tenders by May 25th.

PROVINCES.

AYR.—Additions, sanatorium. Architect, A. Stevenson, Cathcart Street, Ayr.

BARNSLEY.—The May Day Green Market, upon the recommendation of the Market Committee of the Corporation, is to be fitted for electric light at an estimated cost of £380.

BARNSTAPLE.—School (£9,273). Architect, P. Morris, 1 Richmond Road, Exeter; builders, G. Pollard & Co., Ltd., Taunton.

BEVERLEY.—Baptist Church (£3,540). Architects, Garside & Pennington, Pontefract & Castleford; builder, R. Potts, Beverley, Yorks.

BIRMINGHAM.—Factory, Regent Place. Architects, Parrott & Antrobus, Colmore Row, Birmingham.

BRISTOL.—School, Southwell Street, Kingsdown (£6,345). Architect, W. S. Skinner, 16 Baldwin Street, Bristol; builder, W. Foster, City Road, Bristol.

COLCHESTER,—Liberal Club premises, Head Street. Architects, Goodey & Cressall, High Street, Colchester.

CROYDON.—Roman Catholic School, Purley Road, Roman Catholic Community, Croydon.

DUNDEE.—Additions to baths (£2,500). Architect, J. Thomson, Commercial Street, Dundee.

GLOUCESTER.—Additions to Shire Hall (£13,857). R. Phillips, Consulting Surveyor, Shire Hall, Gloucester. Builders, Crane & Co., Nottingham.

GREAT YARMOUTH.—Grammar School. Architects, Olley & Haward, Queen Street, Great Yarmouth.

HIRST (Northumberland).—The Clubhouse and Institute is to be wired for electric lighting.

IRELAND.—A Local Government Board inquiry is to be held into an application by the North Dublin Union Board of Guardians, for sanction to borrow a loan of £2,000 for lighting the Workhouse and North City Dispensaries by electricity.

KILMARNOCK.—Hospital wing (£2,000). Architect, J. Hay, Bank Street, Kilmarnock.

KIRKCALDY.—Skating rink. Architect, W. Williamson, Kirkcaldy.

NORTH SHIELDS.—Church Institute. Architect, J. W. Meadows, Howard Street, North Shields.

PAISLEY, N.B.—Banking premises (£3,000). Architects, Craig & Cook, St. James's Place, Paisley, N.B.

SOUTHAMPTON.—Drill Hall. Colonel R. A. G. Harrison, Territorial Force Association.

SURREY.—The Visiting Committee of the Brookwood Asylum has reported strongly in favour of substituting electric lighting for gas in the asylum buildings, at an estimated expenditure of £4,000.

WEST HAM.—School (including manual training centres). F. E. Hilleary, Secretary, West Ham Education Committee.

TENDERS RECEIVED AND ACCEPTED

BELFAST.—The tender of the British Electric Plant Co., of Alloa, N.B., has been accepted for a circulating pump at the electric power station.

BRISTOL.—The following tenders have been accepted by the Electricity Committee:—Arc-lamp carbons for the year ending April 30th, 1910, Oliver Arc Lamp Co., Ltd., £200; completion of electric wiring of Avonbank power station, Messrs. F. & W. Bracher, £397; supply of coal at Avonbank for nine months to March 25th, 1910, Bedminster Collieries, Ltd., £7,631; supply of coal to Temple Back power station for twelve months ending March 25th, 1910, Princess Royal Colliery Co., Ltd., £1,144.

CHESTER-LE-STREET.—The Guardians have accepted the tender of the County of Durham Electric Power Distribution Co. for the installation of a 3½-h.p. motor at the bakery at £51.

EDMONTON.—The Guardians have accepted the tender of Messrs. Nightingale & Co. for the erection of a transformer house and switch-house at £1,038.

FALKIRK.—The contract for the construction of the permanent way of the extension of the Falkirk and District Tramways Co. lines to Laurieston has been placed with Messrs. Alexander Scott & Co. The British Insulated & Helsby Cables, Ltd., are supplying the overhead equipment.

GOVAN.—The tender of the Lancashire Dynamo & Motor Co., Ltd., has been accepted for motors of 5 h.p. to 30 h.p. for the ensuing year. This is the sixth year in succession the company have received this order.

LONDON: *London County Council.*—Messrs. Dick, Kerr & Co.'s present contract with the Council is to be extended to include the conduit trackwork and roadwork of that portion of the tramways from Cambridge Road via Mile End Road to Burdett Road, and the alterations required to the trackwork between Burdett Road and Bow Bridge for the overhead trolley systems. The estimated cost is £30,000.

The following tenders have been obtained from selected firms for the supply of the overhead electrical equipment required in connection with the reconstruction, on the overhead trolley system of electric traction, of the tramways in Bow Road between Burdett Road and Bow Bridge, and for the line to the Bow tramways car-shed. Four firms were invited to tender, but one of them, the British Thomson-Houston Co., Ltd., was unable to do so:—Dick, Kerr & Co., Ltd. (recommended), £2,511; British Insulated & Helsby Cables, Ltd., £2,612; Robert W. Blackwell & Co., Ltd., £2,666.

The tender of Messrs. Kirk & Randall, of Woolwich, at an estimated cost of £11,000, for building the first portion of the Abbey Wood car-shed, is recommended for acceptance.

For the provision of heating apparatus for the Holloway car-shed the tender of the Standard Engineering Co., at £446 10s., is recommended for acceptance.

Kensington.—Messrs. E. Newbald & Co., Court Road, Sutton, Surrey, are to carry out the work of installing electric light at the workhouse chapel and Guardians' offices, Marloes Road, Kensington, at £169.

Hammersmith.—The Council have accepted tender of Medways Safety Lift Co., at £167, for the conversion of the lift in the Town Hall from hydraulic power to electrical power.

The Council have accepted the tender of Mr. J. Pugsley, at £510, for the purchase from the Council of three generating sets and alternator. The following tenders have also been accepted:—Supplying and fitting a furnace for boiler, Brown, Duncan & Co., £105 10s. Supplying (*a*) 100 and (*b*) 200 kilowatt transformers: Spagnoletti, Ltd., (*a*) £89; British Electric Transformer Co., (*b*) £175. Supply of cable, (*a*) 1,000 yds. 0·05 H.T., (*b*) 3,000 yds. 0·2 L.T., (*c*) 1,500 yds. 0·05 L.T., (*d*) 1,000 yds. 0·08 L.T., (*e*) 2,000 yds. 0·025 L.T.: Western Electric Co. (accepted for all), (*a*) £115, (*b*) £1,013, (*c*) £205, (*d*) £185, (*e*) £192.

Stepney.—The Council have accepted the tender of Foster Bros., Ltd., for pipework, hot well, &c., at £3,989, and that of the Rees Roturbo Manufacturing Co., Ltd., for motor-driven pumps at £1,969, for the Blyths Wharf power station.

SURBITON.—The Council have accepted the tender of Pasterfield & English (Streatham), at £1,266, for extensions at the electricity station, subject to a satisfactory report by the architect.

YORK.—The Tramways Committee, acting upon the result of the recent poll of ratepayers, which was in favour of the Corporation maintaining the working of the tramways in their own hands, have accepted the tender of Messrs. Dick, Kerr & Co., Ltd., for the construction of the track and electrical equipment at £78,827.

COMPANIES' MEETINGS AND REPORTS

FALKIRK & DISTRICT TRAMWAYS CO.—After placing £1,750 to depreciation, the working for 1908 shows a net profit of £723. No dividend, however, is recommended. The question of introducing halfpenny fares is to be considered by the board. At the meeting last week, the report and accounts were adopted.

POTTERIES ELECTRIC TRACTION CO.—The report for 1908 states that the otal receipts amounted to £108,722. The traffic receipts show a decrease of £3,223, due to the continued depression of trade in the district. After deducting all expenses, including £12,388 for debenture and other interest, there remains a balance of £21,780, including £441 brought forward. Permanent way renewals account is credited with £5,409; depreciation, reserve fund, with £1,000; general renewals account with £2,000; and the dividend, 5 per cent. on the preference shares is paid, leaving £1,121 to be carried forward. The depreciation and reserve account will then stand at £20,000, the debit balance on permanent way renewals suspense account will be entirely written off and a balance of £2,000 will remain at the credit of the general renewals account. In view of the fact that considerable work still remains to be done on the permanent way and rolling stock, the directors recommend that the above increased provisions should be made and the financial position thus improved rather than that the surplus available should be distributed by way of dividends. Capital expenditure during the year amounted to £4,930. The number of passengers carried was 1,326,600 less than in 1907, but the average receipt per passenger was better by 0·7d. The ratio of expenditure to receipts, however, increased from 62 per cent. to 66 per cent. The amount available for dividends is £6,700 less than for 1907, with the result that the ordinary shares, which then received a 4 per cent. dividend, get nothing for 1908.

At the annual meeting on Friday, the report and accounts were adopted. Mr. G. F. M. Cornwallis-West presided. The Chairman regretted that no ordinary dividends were recommended this year, although the revenue would have allowed this to be done. There had, however, been a serious decline in receipts, due to the terrible state of trade in their district, and although working expenses had been reduced to some extent, there had been increases under several heads, especially in the maintenance of permanent way and rolling stock. The traffic receipts, which had decreased by £3,000, were the lowest obtained since the completion of the system. The proposals of the

Digitized by Google

Board with regard to the balance this year would greatly strengthen the financial position, and he thought the shareholders would agree with the course adopted.

CRAIGPARK ELECTRIC CABLE CO.—At the annual meeting last week, the report and accounts given in our issue of April 29th were adopted. Mr. J. T. Fuller, the Chairman, who presided, said that during the year there had been an increased output of cable, although the financial result apparently was not so good as formerly. They were, however, still able to pay a 6 per cent. dividend upon the ordinary shares.

EASTERN EXTENSION, AUSTRALASIA & CHINA TELEGRAPH CO.—The report for the half-year ended December 31st, 1908, states that the gross receipts amounted to £306,889, against £304,416 for the corresponding half-year of 1907. Working expenses absorb £151,507, leaving £155,382. From this is deducted income-tax payable in England, and interest on debenture stock, leaving £137,228. After adding £65,777 brought forward, there is an available balance of £203,005. A dividend of 1¼ per cent. is recommended, making 5 per cent. for the year. It is also proposed to pay a bonus of 4s. per share, or 2 per cent., making a total distribution of 7 per cent. for the year 1908. The sum of £50,000 has been transferred to the general reserve fund, and the balance of £18,005 carried forward. At the meeting on Tuesday, the report and accounts were adopted.

LISBON ELECTRIC TRAMWAYS CO.—At the annual general meeting last week the report and accounts were adopted. Sir Charles Euan-Smith, K.C.B., who presided, stated that in spite of the unsettled political conditions during the year, which had necessarily had its effect upon the commercial situation, their traffic had shown a slight increase. A serious depreciation, however, in the rate of exchange had made a difference of £12,000 to the company, and for this reason the carry forward, after meeting dividends, was only £4,640, as against £13,271 last year.

BRITISH WESTINGHOUSE CO.—The report for 1908 states that the results for the year have been affected by the serious trade depression and severe competition. The trading profits amounted to £64,771, against £92,300 for the previous year, and after deducting mortgage and debenture interest, there is a balance of £1,236, to which is added £11,341 brought forward. After providing for the prior lien debenture redemption fund, however, there is a debit balance of £6,521. In comparison with the three preceding years the directors point out that the turnover is about the same, whilst the expenditure has declined by some 20 per cent. At the same time, there has been a falling off in the volume of home business during the year.

CALLENDERS' CABLE & CONSTRUCTION CO.—The report for 1908 shows a gross profit of £106,721, including a balance of £45,107 brought forward. Deducting debenture interest, preference dividend, and depreciation of buildings, plant, &c., amounting in all to £34,587, there is a balance of £72,134. The directors propose a dividend of 10 per cent. on the ordinary shares, together with a bonus of 5s. per share, carrying forward £45,884. The report points out that the deplorable condition of the engineering trade during the past year has resulted in a restriction of business. No new undertaking of any importance in the electrical industry was carried into effect, and the orders secured by the company were confined almost exclusively to extensions of networks and supply stations already in existence. The metal filament lamp had a temporary effect upon cable orders, but the directors had no misgivings on this account. They looked forward to more rapid extensions of electric supply mains in the metropolis in consequence of the passing of the London Electric Supply Act. The meeting is on 27th inst.

BRUSH ELECTRICAL ENGINEERING CO.—At the meeting on Tuesday, the report and accounts given in our last issue were adopted. A proposal that the meeting should be adjourned for three months, and that a committee of shareholders should be appointed to confer with the Board, did not meet with a seconder. The chairman, Lord Vaux of Harrowden, said the company had been very successful in securing orders for exhaust steam turbine plant, and it was their intention to exploit this branch energetically.

Tramway Strike in Cork.—The strike has come to an end, the matters in dispute having been amicably arranged. The running of the trams was resumed on Sunday morning.

L.C.C. and Electric Lighting Acts (Amendment) Bill.—The Parliamentary Committee of the London County Council have reported with regard to the provisions of the Electric Lighting Acts (Amendment) Bill. They recommend that an amendment should be made making it clear that the Council shall be entitled to be heard before the Board of Trade on any orders or consents affecting London made under clauses 1, 3, 4, 6, 7, and 8; that clause 11 be amended so as to provide that a person shall be entitled to the use of a certified meter without extra charge for such certification by the undertaker supplying electricity, and that the inspector of such undertaker shall take into consideration the size of the meter as being suitable to the requirements of particular premises; that clause 15 shall not apply to existing consumers. (This is the "standby" clause, which is made retrospective by the Bill.)

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £60 10s. to £60 15s. (last week, £60 5s. to £60 10s.).

FIRE.—A somewhat disastrous fire occurred at the Newcastle premises of Messrs. Simplex Conduits, Ltd., 61-65 High Bridge, Newcastle-on-Tyne, last week. The fire broke out on the floors above, and, spreading downwards, completely gutted the building. The firm have, however, opened further premises situated at 60 Pilgrim Street, corner of High Bridge, Newcastle-on-Tyne, and have made the necessary arrangements to obviate any delay in the execution of orders. Complete stocks of material will be carried on the new premises.

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—At the London Bankruptcy Court on Wednesday last, the public examination took place of C. H. W. Biggs, trading as Biggs & Sons, 139 and 140 Salisbury Court, London, E.C. The accounts disclosed total liabilities £10,418 5s. 1d. (£9,270 16s. 5d. ranking for dividend), and assets estimated to produce £3,406 12s. 3d. net. In answer to the Official Receiver, the debtor stated that since 1884 he had carried on the business of a printer and publisher. He removed to the above address in 1888, and since 1906 had traded as Biggs & Sons. He took the title when his youngest son came of age. His sons were not partners, but were employed by him in the business, and he took the name of Biggs & Sons because he thought that in the ordinary course of events, when he died, the business would go to them. For a short time, in 1888, he was in partnership with a Mr. Debenham, who afterwards died. From 1879 to June, 1908, he was a director of a limited company which owned "The Contract Journal." He was employed up to September, 1908 to edit, and from 1899 to that date also to print and publish that paper at a remuneration of £500 a year. Since 1884 he had also published the "Electrical Engineer," and in October, 1908, commenced a third paper, "The Contractors' Record and Municipal Engineering." He sold this paper to his daughter-in-law in the following November, and she, in turn, sold it to a company formed to acquire it. The consideration for the sale by him was £500, £250 in cash, and £250 in £1 shares in the company, which latter were issued to two of his sons, who had found the money for the venture. Since that date he had been employed by the company to edit, print, and publish the paper under a profit-sharing arrangement, but nothing had yet been received in respect of it. He attributed his insolvency principally to his liability to the representatives of Mr. Debenham, deceased, for money borrowed and put into the business, and to expenses incurred in commencing the paper last-mentioned, but also to interest on loans, and to his net income during the last twelve months having been insufficient to meet his household and personal expenditure. The examination was ordered to be concluded. The following are the chief creditors:—Bennet, A. R., London, £27; Debenham, T. N., deceased, trustees of, £5,028; City of London Electricity Co., Ltd., London, £15; Crook, Mrs., Waddeston, £500; Gas Light & Coke Co., London, £22; Herring Dewick & Co., London, £569; Lacey, Mrs., Torquay, £986; Lewsey, H. A., London, £223; International Trade Exhibitions, Ltd., London, £16; Shackell, Edwards & Co., Ltd., London, £114; Penrose, A. W. & Co., Ltd., London, £41; Slogger Engineering Works, Ltd., London, £10; Biggs, C. H. and E. J., London, £20. There are fully-secured creditors amounting to £257, and partly-secured creditors amounting to £762. The following are preferential creditors:—Right Hon. Earl of Onslow, Guildford, £112; Ellis, R. E. & Son, London, £106; Bullen & Debenham, London, £68; Hornsby, F. W., London, £100; Palmer, Miss, London, £19; Weekes, R. W., Bromley, £14; Rates, £87; Wages, £112.

The first meeting in the bankruptcy of Joseph Cunington and H. Allison, trading as Laing, Wharton, & Cunnington, electrical engineers and contractors, 7 Great Newport Street, London, will be held at the Bankruptcy Buildings, Carey Street, London, on May 25th, at 11 a.m. The public examination will be held on June 23rd at 11.30 a.m. at the same place.

The first meeting in the bankruptcy of John Middleton and Alfred Daniels, electrical engineers, 11A King Street, Dover, will be held at the Official Receiver's Office, Castle Street, Canterbury, on May 22nd at 10.30 a.m. The public examination will take place on May 27th at 10 a.m. in the Guildhall, Canterbury.

The firm of Messrs. Marples, Leach & Co., Ltd., is to be wound up voluntarily. The creditors' meeting is on May 29th, at 28 Artillery Lane, E.C., at 11 a.m. Particulars of claims should be sent to the liquidator at that address by July 14th.

LARGE GAS ENGINE ORDERS.—Messrs. Ehrhardt & Sehmer, whose agents in this country are the Key Engineering Co., of London and Manchester, have recently received three repeat orders, aggregating 3,000 h.p., for large gas engines, to be direct coupled to electric generators. Last week they received a repeat order from the Skinningrove Iron Co. for a 1,200-h.p. engine to work on blast-furnace gas. This is an extension to two smaller engines of the same make now in course of erection.

Digitized by Google

They have also just received an order for an identical engine for use in a large chemical works in this country where one of their 1,200-h.p. engines has been running on Mond ammonia recovery producer gas during the past two years.

ELECTRIC LIGHTING & TRAMWAYS ACCESSORIES CO.—This company has started in business at 73 and 75 Finsbury Pavement, London. Mr. A. W. Boreham, who was for many years with the Consolidated Supply Co., Ltd., and the British Electric Car Co. Ltd., is Manager.

WITTON KRAMER ELECTRIC TOOL & HOIST CO.—Mr. H. V. Kramer, late managing director of Kramos, Ltd., of Bath, has now severed all connection with that company, and has formed, in conjunction with the Witton Engineering Works, Birmingham, the Witton Kramer Electric Tool & Hoist Co., to carry on the manufacture and sale of the electric suspension and mono-rail trolley hoists, electro lifting magnets, electric portable drills and grinders, and brake solenoids, which he introduced when he formed Kramos, Ltd.

MISCELLANEOUS CITY NOTES

BRITISH ELECTRIC TRACTION CO.—The Honble. Arthur Stanley, M.P., who, as we announced last week, recently joined the Board of the British Electric Traction Co., has retired, pending the determination of a business in which he has conflicting interests.

OLDHAM, ASHTON, & HYDE ELECTRIC TRAMWAYS CO.—A final dividend of 7 per cent., making a total of 6 per cent. for the year, has been declared.

VERITY'S.—Subscriptions have been invited this week for an issue of £60,000 5 per cent. mortgage debenture stock at 97½ per cent.

APPOINTMENTS AND PERSONAL NOTES

A chief electrical engineer and manager is required for the West Ham Municipal Electricity Department. Applications by June 1st. (See an advertisement this week.)

Mr. H. H. Clare has been appointed station engineer to the Woolwich electricity undertaking at a commencing salary of £180 per year. Mr. H. W. Mansfield, the present leading fitter, has been appointed works foreman on probation for six months at a commencing salary of £150 per annum.

The Sheffield Corporation require a Deputy Manager and Chief Assistant Engineer to the Electric Supply Undertaking. Salary, £300 per annum, rising by increments of £25 to £400 per annum. Applications to Mr. S. E. Fedden, the General Manager, by May 25th. (See advertisement on another page.)

Mr. A. N. Banister, who has resigned the Managership of the Norwich Electric Tramways Co., Ltd., has been presented with a gold watch, and Mrs. Banister with a silver tea-caddy by the staff and employees. Mr. Banister has also been presented with a silver salver and cake basket by a few of his Norwich friends.

Mr. S. B. Langlands, Inspector of Lighting to the Edinburgh Corporation, has been granted an increase of salary of £50, making a total of £400 per annum.

The managers of the Dundee Technical College require a lecturer in electrical and mechanical engineering at a salary of £350 per annum. Applications by June 15th.

The West Ham Education Committee recommend that the salary of Mr. P. R. Friedlaender, lecturer in the Electrical Engineering Department, be raised from £200 to £230 per annum by annual increments of £15.

Dr. Lewis Jones, of the Electrical Department of St. Bartholomew's Hospital, has been appointed President of the Electromedical Conference, to be held in London in July.

A New Metal Filament Lamp.—The Electric Company (121-125 Charing Cross Road) make the important announcement that they are now in a position to deliver "Aegma" metal filament lamps from 16 c.p. for 100 to 130 volts with bulbs of a similar size to those of ordinary carbon filament lamps, at a list price of 3s. each.

Postal Strike in Paris.—In spite of the declaration of a general strike in Paris amongst the telegraph operators and clerks, matters are now practically normal again. There has been some cutting of telegraph wires, however.

St. Petersburg Tramways.—The municipality of St. Petersburg has under their consideration the sale of the tramway undertaking to a private company, which will carry out the development and electrification of the system. A syndicate has submitted a proposal to buy and work the system for an immediate payment of 20,000,000 roubles, and a further payment of 30,000,000 roubles spread over four years.

Electrical Propulsion of Ships.—A lecture was given by Mr. W. P. Durtnall on Tuesday night at the Queen's Hall, Chatham, on "The Application of Electrical Propulsion to Warships," before the Royal Naval Artificers and Engineers, in the course of which figures were produced to show that with Mr. Durtnall's patent system of electric transmission a saving of no less than 26 per cent. in coal consumption would be made in battleships of the Dreadnought type, as against direct steam turbine drive.

NEW COMPANIES

MOUNTAIN & GIBSON & THORNEWILL.—Registered on May 6th, with a capital of £150,000, to acquire the business carried on by Mountain & Gibson, Ltd., at Elton Fold Works, Bury, and to carry on the business of civil, mechanical, electrical, railway, tramway, marine, lighting, ventilating, consulting and general engineers, founders, machinists, builders and contractors, suppliers of electricity, manufacturers of and dealers in railway, tramway and road locomotives, carriages, cars, motor-cars, chassis, omnibuses, trucks, cycles and vehicles, &c. The subscribers are:—M. B. Mountain, Eldon Grange, Bury, engineer: G. M. Gibson, Charlton Manor, Knaresborough, engineer; G. L. Walker, 49 Queen Victoria Street, E.C., engineer; J. D. Totley, Palace Chambers, Westminster, S.W., Parliamentary agent; H. L. Bankes, Orient House, New Broad Street, E.C., clerk; J. H. Hyland, Orient House, New Broad Street, E.C., clerk; H. P. Geard, 144 Boyson Road, S.E., articled clerk. Minimum cash subscription, 100 shares. The number of directors is not to be less than three nor more than seven. The first are:—R. Thornewill, J.P., M.I.M.E., Craythorne, Burton-on-Trent; E. D. Simon, B.A., A.M.I.C.E. (Henry Simon, Ltd.), 20 Mount Street, Manchester; M. B. Mountain; C. Spalding, Burton-on-Trent; G. M. Gibson, B.A., A.M.I.C.E.; and N. M. Lawrence (director of Mountain & Gibson, Ltd.), 82 Cambridge Terrace, Hyde Park, W. Qualification, £250. Remuneration, £100 each per annum. Each share confers one vote. Directors' borrowing powers restricted to the amount of the capital. Registered office: 49 Queen Victoria Street, E.C.

COWPER-COLES ENGINEERING CO.—Registered on April 28th, with a capital of £40,000, to adopt an agreement with Sherard Cowper-Coles & Co., Ltd., A. E. Tugwood (the liquidator thereof), S. O. Cowper-Coles, and J. Macgregor-Laird, and to carry on the business of ironfounders, iron and steel workers, electricians, consulting and electrical engineers, and technical consultants or advisers, &c. The subscribers are:—S. O. Cowper-Coles, 87 Victoria Street, Westminster, electric-metallurgist; C. H. Christie, 15 Cranworth Gardens, Brixton, S.W., clerk; G. Gentry, 43 Wroughton Road, Clapham Common, S.W., engineer. First directors: J. M. Laird and S. O. Cowper-Coles. Qualification, 1 share. Remuneration as fixed by the company. Registered by Williams & James, Norfolk House, Thames Embankment, W.C.

The Highgate Hill Tramways.—As a portion of the Highgate Hill cable tramway, which the London County Council is acquiring in order to convert to electric traction, is in Middlesex, an agreement is to be entered into with the Middlesex County Council for the latter to become owners of this portion, which will then be leased to the London County Council. The Middlesex County Council have now withdrawn their opposition to the L.C.C. (Tramways and Improvements) Bill.

The East London Electrical Exhibition.—The arrangements in connection with the Exhibition of Electrical Machinery and Appliances promoted by the Metropolitan boroughs of Shoreditch, Stepney, and Hackney, referred to in a recent issue, have now reached a more advanced stage. The Exhibition will be held at the Pitfield Street Baths, Hoxton, from October 18th to the 30th inclusive, and the Manager of the Exhibition is Mr. C. Newton Russell, Electrical Engineer to the Shoreditch Borough Council, Coronet Street, Shoreditch. Special attention will be given to the most up-to-date forms of electric lamps, fittings, &c., especially suitable for business premises, shops, factories, &c. Although a small charge for space will be made, there will be no charge made for electric current, *i.e.*, within reasonable requirements. The supply will be given on the direct-current three-wire system at 240 volts for lighting, and 480 volts for motors.

Telegraph Traffic and Movements of Cable Ships.—Telegraphic communication with Venezuela was restored on the 12th inst. at reduced rates, viz., 5s. 2d. a word from London, as against 7s. 2d. and 7s. 7d. per word charged before the quarrel between the French Cable Co. and President Castro. There had been no telegraphic facilities since Jan. 11th, 1906. The line between Bagdad and Bassorah was restored on the 11th inst., while on the 13th inst. the cable between Dakar and Conakry became incapacitated. On the 15th inst. the cable between Obock and Djibouti was again in working order, the interruption having lasted since April 14th last. Telegraphic communication between Medan and Oleleh was restored on the 17th inst., while an interruption of short duration occurred between Bagdad and Bassorah on the same day. The fleet of cable steamers has been increased by two boats, one belonging to the Telegraph Construction & Maintenance Co., and the other to the United States Signal Fire Service. The *Contre Amiral Caubet*, belonging to the French Cable Co., has been repairing one of the company's main sections; the c.s. *Minia*, belonging to the Anglo-American Telegraph Co., was back in Halifax, Nova Scotia, on the 14th ult., but left again on the 20th. The c.s. *Mackay-Dennett* has been busy off Newfoundland surveying the route for the new cables and selecting a landing place for the Commercial Cable Co. It will be remembered that two of the existing cables are to be diverted from Canso *via* Newfoundland.

Digitized by Google

DIESEL ENGINES FOR GENERATING STATIONS

THE Paper by Mr. A. J. J. Pfeiffer entitled, "Economics of Medium-sized Power Stations," which was read before the Institution of Electrical Engineers last Thursday, was devoted to an investigation of the economy of small generating stations worked by Diesel engines as compared with steam or gas engines.

Briefly, the cycle of operations is as follows in a four-cycle Diesel engine :—(1) Air at atmospheric pressure and temperature is drawn into the cylinder. (2) This air is compressed to about 450 to 500 lbs. per square inch and becomes heated far above the ignition-point of oil, the temperature being about 900° F. to 1,000° F. (3) Oil fuel is blown into the cylinder 1° or 2° before the completion of the compression stroke (by means of air compressed by a special pump) at a constant pressure of 700 to 800 lbs. per square inch, depending upon the nature of the oil used. During the first part of the stroke the combustion, over a period determined by the amount of fuel to be sprayed in, is carried on at practically constant pressure, and thereafter the products of combustion do work by expansion. (4) The waste gases are exhausted to atmosphere, the exhaust pressure at the cylinder being about 40 lbs. The principal difference between the Diesel oil engine and the ordinary gas engine lies in the fact that only the air used for combustion is compressed, the fuel being gradually injected after this compression of the air has taken place, the resultant great advantages being the elimination of the possibility of premature ignition, no sudden increase of pressure, and, therefore, less strain on the working parts.

Some manufacturers of Diesel engines are adopting the 2-cycle and also the double-acting principle for large units, giving one, two, or four working strokes per revolution. To obtain the 2-cycle result, the principle of scavenging is resorted to by blowing fresh air at a pressure of 5 lbs. into the cylinder near the end of stroke 3, clearing out the waste exhaust gases, and filling the cylinder with a new charge : Strokes 1, 3 and 4 of the 4-cycle engine are thus combined.

In the single-acting four-cycle engine as usually employed for moderate-sized sets, each cylinder is provided with three valves, for exhaust, inlet for air, and inlet for fuel, one cylinder, in addition, being supplied with a starting valve. The plunger of the fuel pump is driven directly from the vertical shaft, through which the drive is taken to the cam shaft. By an arrangement of levers and eccentrics, connected to the governor, the time is regulated during which the suction valve is kept open, thus determining the amount of fuel for varying loads. In the earlier types of engines it was customary to provide each cylinder with its own fuel pump, but of late it has been found simpler to accomplish the feeding by one pump and fuel circuit for all cylinders, thus assuring an equal amount of fuel to each cylinder at all loads. A 3-stage air compressor is direct coupled to the engine. This takes in fresh air, compresses it in three stages to 75, 400, and 750 lbs. respectively, the air being cooled after each stage by passing through water-cooled chambers. The compressed air is stored in a reservoir, and serves to inject the fuel into the cylinder against the high cylinder pressure. The air-starting reservoirs are connected by an overflow valve with the air-blast reservoir. The engine is started off as an air engine by the compressed air stored during a previous run, the pressure being about 750 to 800 lbs. per sq. in. When the engine has attained practically full speed the fuel valve is made to engage the cam and ignition takes place. The starting-valve lever is at the same time thrown out of gear and the engine is ready for work. This operation is carried out by one man, and is completed in from 1 to 2 minutes.

An oil-engine plant burning crude petroleum of about 18,500 B.Th.U. per lb. has a thermo-dynamic efficiency, including generator loss of about 30·5 per cent at full load, 29·2 per cent. at three-quarter load, and 24·8 per cent. at half load.

The sizes of Diesel oil engines have increased rapidly of late. Three to four years ago a 450-b.h.p. unit was the largest actually running, while to-day there is in service a vertical 800-b.h.p. set of 4-cylinder single-acting 4-stroke type, having a speed of 150 r.p.m. This latter engine has only the cylinder and air pump water jacketed, and it is probably the limit of size to which engines can be constructed without having recourse to water cooling the piston, exhaust valves, &c. For larger outputs some manufacturers are devoting themselves to the development of the 2-cycle engine, the largest at present running being of 750 b.h.p., while others of equal repute are adhering to the simpler 4-cycle principle, their latest design being based on the horizontal twin-tandem double-acting type giving four working strokes per revolution, and on this design they are prepared to construct units up to 4,000 b.h.p.

After a few remarks on the reliability of plant of this nature, and the absence of stand-by losses, it was mentioned that the overload capacity available was limited to about 15 to 20 per cent. The speed regulation was stated to approximate to that obtained in a steam engine, and to be capable of being made to come to within 3 per cent., or even less, between no load and full load. As regards satisfactory conditions of parallel running, a speed variation of 1/250th to 1/300th can easily be obtained with a 4-cylinder 4-cycle single-acting engine with a small flywheel.

A point to be guarded against in working an oil plant in cities or towns where restrictions are severe is that of smoke, which comes into evidence when engines operate below ½ to ⅛ full load, the cause being the imperfect combustion of the oil fuel. For plants having low load factors, therefore, it would be advisable, in addition to the advantage of economy, to put in at least one small unit to cope with light loads, or possibly to instal accumulators.

The type of engine under consideration can burn almost any liquid fuel; but generally, and especially in Great Britain, petroleum residue from the Dutch East Indies, Texas, and Roumania is used, while on the Continent gas oils and paraffin oils are successfully employed. Crude petroleum residue costs

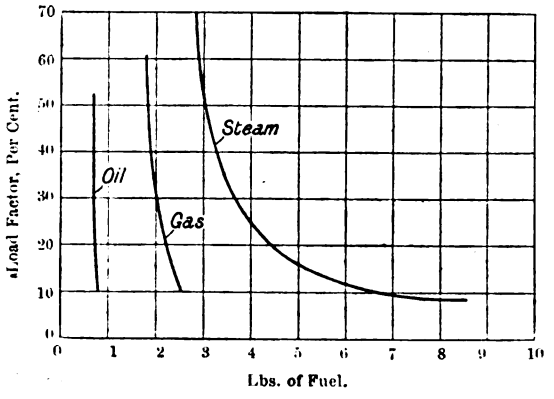

FIG. 1.—TOTAL FUEL CONSUMPTION PER KILOWATT-HOUR GENERATED.

at present between 50s. and 55s. per ton at ports in England; in South America about 60s. per ton, and in Indian ports about 45s. to 50s. per ton.

The Paper then passes on to a detailed comparison of steam, gas, and oil plant for a typical case of a plant dealing with a maximum effective load of 1,600 kw., and considers separately the case of a lighting load, a lighting and power load, and a traction load, with load factors respectively of 17·5 per cent., 33 per cent., and 52 per cent.

The division of engine units is assumed as follows :—For the lighting station, five 400-kw. sets (1 reserve) and one 100-kw. set; for the lighting and power station, four 400-kw. sets (1 reserve), and two 200-kw. sets; and for the traction station, five 400-kw. sets (1 reserve).

For all the above it is assumed that five (1 reserve) units are provided for both boiler and producer plants.

The following are the figures taken for capital costs per kilowatt installed :—

Steam Plant :—

Machinery, including high-speed vertical compound engines with direct-coupled generators; water-tube boilers, superheaters, and stokers; condensers, complete with pumps; economisers; cooling towers; auxiliary pumps, &c.; piping; switchboard and cabling, and crane. £16·0.

Buildings and foundations, £8·5. Total £24·5.

Gas Plant :—

Machinery, including vertical engines (single-acting tandem) with direct-coupled generators, pressure-producer plant, auxiliary machinery; cooling tower, piping, switchboard and cabling, and crane. £17·5.

Buildings and foundations, £6·0. Total, £23·5.

Oil Plant :—

Machinery, including vertical 4-stroke engines, with dire t-coupled generators, and all necessary pumps, air vessels, &c.;

Digitized by Google

piping, auxiliary pumps, cooling tower, switchboard and cabling, and crane. £19·5.

Ditto, for a 2-cycle engine, £17·5.

Buildings and foundations, £5·5. Total, from £23 to £25.

From the above it would seem that the difference of capital outlay between the three high-grade plants is but nominal.

In a consideration of the amount of fuel required for each class of plant, the curves shown in Fig. 1 were given, and taking the three cases in question, the fuel consumption during the load and stand-by periods were worked out. Finally the following table of total works costs was given:—

Table of Estimated Works Costs.

(Maximum Load, 1,600 kw.).

Pence per unit generated.

	Steam At 15s. per ton.	Gas. At 25s. per ton.	Oil. At 60s. per ton.

Total	**0·422**	**0·418**	**0·338**

In Figs. 2 and 3 are plotted graphically the results shown in the table, for total works costs per effective unit of output for steam and gas plants respectively, at different load factors and varying prices of coal. The dotted lines are what may be termed "parity curves," the intersections with the works cost curves indicating the price of coal at which the total works cost of steam and oil or gas and oil plants are equal, under

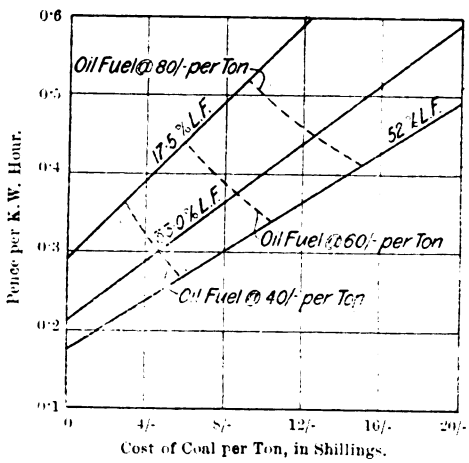

FIG. 2.—STEAM PLANT. WORKS COST IN PENCE PER KILOWATT-HOUR GENERATED.

various assumptions of oil costs. These curves cover savings in works cost only. There still remains to consider the effect on these curves of the following fixed charges, including interest and depreciation, management, rents, rates, and taxes, &c.

As the capital costs of high-class steam and gas plants of medium size seem to be practically equal to those of oil-engine installations, the savings shown will not be appreciably affected by the charge for interest and depreciation, which remark likewise holds good for management, &c., which can be considered a constant for the three types of plants. Rents, rates, and taxes will show an additional saving, due to the lesser land area required for an oil-engine plant, but in the majority of cases this will probably not be an important factor.

The above results show that the internal combustion oil-engine working on the Diesel principle possesses advantages both from a technical as well as a commercial standpoint. Its limit of application depends primarily upon relative fuel costs, which for Great Britain would mean that it probably cannot compete with steam or gas engines in the immediate neighbourhood of coal centres; but a large field seems open for the consideration of this type of oil engine, especially for colonial and foreign work where coal costs are high.

The question is then investigated whether a Diesel plant can take the place of sub-station distribution, in connection with very large systems where generating costs are low, and a

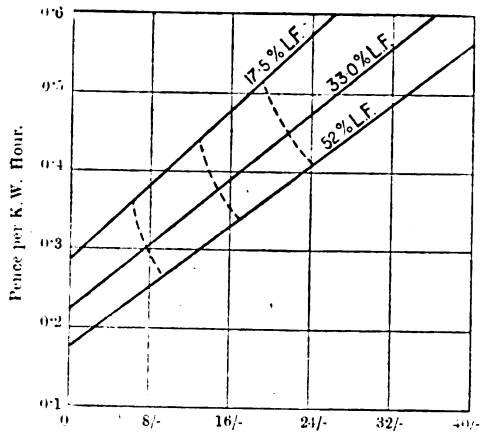

FIG. 3.—GAS PLANT—PENCE PER KILOWATT-HOUR GENERATED.

case is gone into of a large distributing system having an outlying central station feeding ten sub-stations, each sub-station having the output and size of the oil-engine plant considered in the foregoing.

On the assumption that the overload capacity of the converter sets is made use of to the extent of 15 per cent. in excess of the Diesel engine at the times of maximum demand, and allowing 25 per cent. for spare, the plant installed at each sub-station would be 1,750 kw., as against 2,000 kw. of oil-engine plant. The capital cost of the ten sub-stations is taken as £175,000, reckoning £4·75 per kw. for plant, £2·66 per kw. for buildings, and £3·25 per kw. for land, and the cost of the transmission mains at £150,000.

Assuming a diversity factor of 1·25, the capacity of the central station would be 15,500 kw., allowing 20 per cent. for spare at £20 per kilowatt, the capital cost of the central station would be £310,000, giving a total of £635,000.

If in connection with the ten local Diesel plants we allow £5 per kilowatt installed as the value of land, the total capital involved, based on 2-cycle engines, would be £560,000, as against £635,000 for the central station sub-station scheme.

The following tables were then given of the works cost for the sub-stations and central station:—

Sub-station.—Pence per unit

Sub-station load factor—	17·5 per cent.	33 per cent.	52 per cent.
Oil, waste, stores...	0·005	0·004	0·003
Salaries and wages	0·070	0·055	0·040
Maintenance and repairs ...	0·025	0·020	0·015
Total per unit	**0·090**	**0·080**	**0·060**

Central Station.—Pence per Unit of Central Station Output.

Central station load factor—	25 per cent.	49 per cent.	76 per cent.
Coal at 14s. per ton	0·305	0·230	0·200
Oil, waste, water, and stores	0·010	0·008	0·007
Salaries and wages	0·050	0·035	0·028
Maintenance and repairs ...	0·055	0·043	0·037
Total per unit	**0·420**	**0·316**	**0·272**

Some of these figures were stated to have been founded on the figures given in Mr. Rider's Paper, read before the Institution a few weeks ago. Capital charges were then investigated on the basis of interest at 5 per cent. and depreciation at 6 per cent. for machinery, 2 per cent. for buildings, and 3 per cent. for cables, &c. The following table shows the comparative figures arrived at for working costs, not including management, rates and taxes, &c.

Digitized by Google

Total costs, pence per unit.

Local station load factor.	17·5 per cent.	33 per cent.	52 per cent.
Central station sub-station—			
1. Works cost—coal at 14s. ...	0·580	0·447	0·376
2. Interest and depreciation ...	0·536	0·280	0·180
Total	**1·116**	**0·727**	**0·556**
Diesel plant—			
1. Works cost—oil at 50s.	0·396	0·338	0·303
2. Interest and depreciation ...	0·500	0·267	0·169
Total	**0·896**	**0·605**	**0·472**
Difference in favour of Diesel plants	**0·220**	**0·122**	**0·084**

Judging by these results it would appear that under the above assumptions the local Diesel plants can be operated cheaper than a system of a large outlying central station distributing power by means of converting sub-stations.

It would seem therefore, concludes the author, that engineers whose central station capital and operating costs are approximately equal to or higher than those assumed above will, therefore, find it well worth their while to give the Diesel engine due consideration in connection with either extensions to existing central stations, or in cases where it is a question of supplying power at points so far removed from the main station as to involve heavy additional capital and operating expenditure in connection with transmission and conversion. Cases may arise where conditions and considerations vary appreciably from the assumptions made use of in the foregoing calculations, but it is hoped that the method of arriving at the above results shows sufficient detail to permit of special problems being easily solved.

After reading the Paper in abstract, the author remarked that his contention as regards the economy of Diesel engines for sub-station use had received some confirmation in the fact that the Charing Cross and City Company had had two 550-kw. Diesel sets running for the last six months for a similar purpose, and that six more sets were to be installed. The price of fuel in this instance was at present 48s. per ton.

DISCUSSION.

Mr. J. H. RIDER (Chief Electrical Engineer, London County Council Tramways), in opening the discussion, pointed out that towards the end of the Paper the author had given the capital cost of ten sub-stations at £175,000, based upon figures which he (Mr. Rider) had given in his recent Paper as the cost of the L.C.C. Shoreditch sub-station. As a matter of fact, this was the most expensive sub-station of the whole of the County Council system, and the figure of £3·25 per kilowatt for land referred to a site which cost £10,000. There was, however, another sub-station on land which had only cost £825, and the average cost of all the L.C.C. sub-station sites was only £4,000. A similar explanation could be given with regard to buildings, and it was clear that the author had gone somewhat astray in taking these figures as his basis. With reference to the table of costs per unit of sub-station output, he did not know what sub-station the author had in his mind when he gave an operating cost of 0·80d. per unit on a 33 per cent. load factor. The figures for the whole of last year's working of the London County Council's tramway system—which were not hypothetical figures—were as follows for the same load factor:—Oil waste and stores, 0·001d. per unit (and not 0·004d.); salaries and wages, 0·041d. (and not 0·055d.); maintenance and repairs, 0·007d. (and not 0·02d.), making a total of only 0·049d. per unit, as against the author's 0·08d. With regard to the table dealing with pence per unit of central station output, the author did not take the figure which was given in Mr. Rider's Paper of 0·018d. for maintenance and repairs, but had taken a hypothetical figure three times as large, namely, 0·045d. If this correction were made in this table, on a 49 per cent. central station load factor, the pence per unit of central station output would be 0·291d., and not 0·316d., as given by Mr. Pfeiffer. He was now able to give some new figures based on actual costs, since January 1st of this year, when the load was very much more uniform than during the period he had dealt with in his Paper. The cost per unit of central station output was 0·261d., instead of the 0·291d., which he previously gave, and coal had been reduced from 0·23d. to 0·197d. If these corrected figures were taken and applied to the author's comparative table, instead of a difference in favour of Diesel engine plants, on a 33 per cent. load factor of 0·122d., the benefit would be on the side of the central station and sub-station scheme. The total cost on this load factor for a central station sub-station scheme was reduced from 0·727d. to 0·634d., and if the price of oil was taken at 60s. instead of 50s.—which he regarded as below the average—the total cost of the Diesel plant would be 0·641d. instead of 0·605d. He would like to know whether the author seriously thought that a Diesel oil engine sub-station scheme was workable in a large city. It was one thing to buy a piece of land in a city, and put down a motor generator sub-station where the plant was quiet, but it was another thing to put down upon such a site oil engines which involved the use of water-cooling towers, silencers, and water tanks. Another point to be taken into consideration in comparisons such as these, was the small overload capacity of Diesel engines compared with motor generators. The latter had anything from 50 per cent. to 100 per cent. overload, and they often had to work at this for hours together, whereas 15 per cent. to 20 per cent. was apparently the limit for Diesel engines.

Mr. W. B. ESSON said that a few years ago he purchased from Messrs. Sulzer Brothers, one of the makers of the Diesel engine in Switzerland, the first 300-h.p. engine made, on behalf of the Hong Kong Electric Supply Co., who were then giving up steam engines, and several further engines of this pattern were afterwards put in. The oil consumption, month by month, was 0·72 lbs. per kw.-hour, with an average load between ⅜ and ⅞ full load. Stand-by losses were practically non-existent with oil engines, and provided such engines as were running were fully loaded, the oil consumption was practically independent of the load factor, but the author had greatly exaggerated the stand-by losses of steam engines, and in his opinion the curves in Fig. 1 vitiated the whole of the comparison between the oil engine and the steam engine. He had had to advise recently upon some plant for Calcutta, where oil was very cheap, and coal was very dear, and the question arose as to whether they should have ordinary oil engines or Diesel engines. Although, however, the ordinary oil engine used 87 tons of oil per annum against 37 tons by the Diesel engine, it came out cheaper to use the former because of the extra cost of depreciation and interest on the capital in the case of the Diesel engine. Another case coming within his knowledge nearer home, demonstrated that although a suction gas plant cost more for fuel, there was not enough saved on the Diesel engine to pay for the extra interest and depreciation. The author had given the cost for oil at 48s. per ton, but only quite recently Messrs. Mirrlees, Bickerton & Day, who made these engines in this country, had told him that Diesel oil delivered into their works cost them 55s. per ton. In London the price would be 51s. 6d.

Mr. H. L. DIXON (Chief Engineer, Leatherhead & District Electric Supply Co.), said that owing to the very high cost of operation with steam plant, his company, under the advice of Messrs. Handcock & Dykes, had installed Diesel engines, and the costs were so largely ahead of the old figures that, in spite of the heavy capital charges, there was a considerable profit. Although it was a very small station, the generating costs were only 0·27d. per unit. The cost of repairs was only about 40s. in three years. He knew of another station where a few pounds would cover the cost of repairs during the period of six years. These engines were very clean, and gave perfect combustion. It was only necessary to clean the cylinders once a year. The ease of working was remarkable, and the man who drove the engines at Leatherhead was an ordinary stoker who had been taught to turn on the compressed air and oil up. They got away with these 120-h.p. engines from cold to full load in 45 seconds, and the load could be transferred from one set to another before the one set had time to slow down. The particular engines at Leatherhead were of the Sulzer make.

Mr. H. W. HANDCOCK (Messrs. Handcock & Dykes) gave some further figures with regard to the Leatherhead works. In 1905, when the steam plant was at work, the cost of fuel per unit generated was 1·044d., and total works costs 1·933d. per unit. In 1907, when the Diesel oil engines were at work and dealing with the whole of the load, the cost of fuel was 0·3245d., and total works costs 1·238d. In 1908 the cost of fuel was 0·29d., and the total works costs 0·72d., so that despite metal filament lamps, they were able to show their shareholders quite a comfortable little dividend. The average cost per ton of oil delivered in tanks at Leatherhead Station was 63s. in 1906, 66s. in 1907, 70s. in 1908, and 66s. in 1909. He did not think anything was so unsettling in dealing with these engines as the large fluctuations in the price of oil. When he first considered the matter, the price was 40s. per ton, and he had been told that it might go up to 90s. Others had stated that it might go down to 35s., and if only those who were interested in the oil trade could see their way to maintain the supply at a fairly even price, he was sure that Diesel engines would be used much more extensively than they were at the present time. Another station of which he had some particulars was Hindhead. Here the fuel was more expensive owing to the necessity for carting it about 900 feet up. In 1904, when steam plant was in use, the cost of fuel per unit generated, working non-condensing, water being scarce, was 0·67d. In 1906, when the Diesel engines were at work, this had dropped to 0·452d., and in 1907 to 0·356d., and although in 1908 this had increased to 0·452d., there was no doubt that taking it altogether in small stations a very great advantage was to be obtained by the use of Diesel engines. At the same time, it was only fair to say that more skilled attention was required than with the average steam engine. On the other hand, provided the engine was properly looked after, the repairs of a Diesel engine were practically nil. With regard to the comparison in the Paper with gas plants, he had obtained equally economical results with the gas engine, and there was no doubt that small suction gas plants could give

Digitized by Google

an extremely good account of themselves. The race in future between oil and gas engines would be a very close one indeed, and an important factor would be the question of capital cost. If they were laying out a station or a company, naturally they would set the depreciation in accordance with what they believed would be the life of the engine; if, on the other hand, it were a local authority, where the period of the loan was abnormally short, it might pay to take the gas engine as being the cheaper, although under certain conditions, with dear fuel, it might cost more to run it.

Mr. H. M. SAYERS pointed out that one of the features of the tests which had been given by many people was their remarkable consistency. Figures of from 0·42d. to 0·46d. per b.h.p.-hour generated covered almost the full load range, regardless of the size of the engines. This was an advantage not shared by the steam engine, nor to nearly the same extent by the gas engine. Nevertheless, the Diesel engine had not made the progress which should be expected from its theoretical superiority. He thought that the natural conservatism of the British engineer was not the only reason, and suggested that the companies concerned in the sale of these engines had been too reluctant in giving inquirers full details of the machines, and that the prices of the engines were higher than they need be. A most important matter was the uncertainty as to the price of oil. His own experience of fluctuations had been the same as Mr. Handcock's, namely, from 42s. to 75s. This was very annoying and very disturbing, and one hardly liked to recommend the use of a plant the cost of the fuel for which varied so much in price. At the same time, he ventured to think that this uncertainty would not be so marked when there was a large demand for oil, and that the number of sources of supply would then increase. It was not generally recognised that a very large quantity of fuel oil could be produced in this country, if it were worth while, from materials which exist in great abundance. Bituminous coal could be used, for example, by distilling at a moderate temperature, and Mr. Sayers even went so far as to suggest that pipe lines from the coal pits to the big towns might assist in solving the problem. Lignite would also produce good oil, and peat could be distilled and give out a fair amount of pure oil. Indeed, there was once a flourishing oil industry in Ireland using peat as raw material.

Mr. LEONARD ANDREWS (Key Engineering Co.) showed a diagram in which he had reproduced Mr. Pfeiffer's curves of thermal efficiencies of steam and gas plants at different load factors, and in which he had also plotted the actual efficiencies obtained at 30 steam and gas installations, as published in his recent Paper. It would be seen that the author's hypothetical curves coincided with the actual results for both steam and gas. He thought that the author's costs for steam engines were rather lower than those actually obtained in practice, and he referred to the table of costs of steam stations, taken from actual results, which was given in the Paper recently read by himself and Mr. Porter. Mr. Esson's figure of 0·72 lb. of oil per kw.-hour gave a thermal efficiency of 26 per cent., which corresponded very closely with the figures given in the Paper, and which he thought were satisfactory. He disagreed with the author's estimates of fuel costs for both gas and steam plants compared with oil. In the first place, the cost of coal was far too high for an average throughout the country. For gas, the author was still worse, for he assumed 25s. per ton. He thought the average to be taken should be about 12s. per ton. Working out the author's example on this basis, on a 33 per cent. load factor, the figures of 0·5d. for steam, 0·8d. for gas, and 0·7d. for oil became 0·45d., 0·348d., and 0·374d. respectively. In conclusion, Mr. Andrews stated that he was glad to gather from the Paper that the price of steam plant had gone up during the past few weeks. He had been very much criticised a few weeks ago in talking about £14 per kw., but nobody objected to the author's figure of £23·5 per kw.

Mr. H. S. RUSSELL pointed out that although the Paper referred only to medium size stations, there was a large field for the Diesel engine in this country in the smaller stations, and also for light load sets in large stations which had low load factors. Some tests were recently taken in the power-house of the Birkdale Electric Supply Co., where there were three 90-kw. sets, one of which was a Diesel oil engine set. The original intention was to use this set for the peak load only, but they tried the experiment of running it throughout the 24 hours, and using the steam plant on the peak load. The result was that the total costs were reduced to 0·615d. per unit, against 1·131d. per unit when using the steam plant during the daytime, and this good result was obtained in spite of the stand-by losses on the steam plant. Being interested in the Diesel engine, he did not wish to emphasise matters of detail, but would like to refer to one detail in regard to the supply of fuel to the engine. It was true that in the earlier types a separate pump was provided for each cylinder, but this had now been abandoned, and one single plunger pump was used by most Continental makers which supplied all three cylinders. But the practice of one British firm had been to use one pump with a separate plunger to each cylinder, and this ensured equal distribution of the fuel to the cylinders at all loads. Also, in view of the fact that the governing was effected by varying the time during which the suction valve of the fuel pump was opened, it was quite simple to arrange a device by which the suction valve could be kept opened for any cylinder, and the oil returned to the pump reservoir. In this way, in the case of three or four cylinder engines it was possible to cut out one or more cylinders entirely when required. By this means they could work on varying loads much more economically. At Lewes they were working with a four-cylinder engine; they started up with two cylinders, and put in the remaining two as the load came on, and the engine ran perfectly steadily under these conditions. The fuel costs at Lewes were 0·24d. per unit, with oil at 51s. 3d. per ton. The author had spoken of the two-stroke cycle engine as if it were something new, but this type was made in this country seven years ago, but was found unsatisfactory, and was abandoned. It was a mistake to think that the use of the two-stroke cycle engine would necessarily cheapen the cost of construction. A limitation was imposed in Diesel engines, as in all internal combustion engines, by the heating, and a consideration of this showed that it was only possible to run with a stroke cycle at half the speed, and that, therefore, nothing was gained in cost. The author had mentioned that the engines ran without smoke at ⅛ or ¼ full load, but his own experience was that all engines would run quite smokelessly at ¼ or ⅓ load, and by using the multi-plunger pump they could go still lower. The feeling of the makers was that no engine was satisfactory unless it was absolutely smokeless, and there should be no smoke from the exhaust except at starting up or when there was no load on at all. From the figures he himself had been able to get he quite disagreed with Mr. Andrews that the author had dealt very much too leniently with the gas figures; in fact, if he had erred at all, he had given Diesel engine figures higher than they actually were. From figures of suction gas plants which he had collected there was not a single one which seemed to be able to work at less than 2d. per unit for the total costs against 0·4, 0·5, or 0·6d. for the Diesel engine. The author's statement that the Diesel engine took as much lubricating oil as a gas engine was wrong. His firm paid 1s. 2d. per gallon, and used the same oil for cylinders as for bearings, and they had found that the amount of lubricating oil used amounted to only 1½ or 2 per cent. of the quantity of fuel oil. The actual costs of these items in two small stations with Diesel engines and purely lighting loads—much smaller stations than were referred to in the Paper—including oil, waste, water, and stores, were 0·025d. and 0·021d. per unit, whereas the author gave 0·042d. People generally did not recognise how long this engine had been made in this country. The first engine was made 13 years ago, and this particular engine was taken down last year and re-erected at Stockport. On the point of fluctuations in price of oil, Mr. Sayers seemed horrified at a variation of about 52 per cent., but it was within the experience of all that coal prices had varied quite as much as that, and if Mr. Sayers would refuse to recommend clients to use Diesel engines because of that variation, then he ought to refuse to recommend coal to all for fear of a coal strike. Mr. Sayers's view that the extended use of Diesel engines will make any difference in the price of oil seemed absurd. It was a fact that the hundreds of thousands of horse-power of Diesel engines at present working throughout the world, consumed less than 1/1,000 of the total consumption at present known, and as new sources of oil were being constantly opened, it would take hundreds of millions of horse-power to affect the price of oil.

Mr. W. H. BOOTH referred to tests which he had made upon these engines some years ago with fuel containing 19,300 B.Th.U. per lb., from which he found the cost per b.h.p.-hour came out at 0·69d. for quarter load, and 0·449d. for full load, notwithstanding that at the full load test there was a hot bearing. It was absolutely necessary for the working of the Diesel engine that everything should be in good order; in fact, the engine would not work at all if it were in poor condition. Unfortunately, this was not the case with the steam engine, which would always turn round. This particular characteristic of the oil engine, he thought, could be accounted to it as a virtue, for they were always assured that it would run economically. Among the tests which he had made, he had got from 40 to 44 per cent. as the efficiency for the i.h.p., and 30 per cent. for the b.h.p. in a sub-station of the British Electric Traction Co. Considering the enormous temperature of the exhaust and the high pressure, it had occurred to him that something might be done in using this exhaust in turbines, although, of course, that they knew turbines were very inefficient owing to back pressure, and it was, of course, impossible to condense the exhaust of the Diesel engine. A certain amount of power, amounting possibly to about 3 per cent., could be gained, however, by cooling the exhaust. With regard to the remarks of Mr. Sayers as to sources of Diesel oil, the Kimmeridge clay of this country contained a considerable amount of pitch, paraffin, and various other hydro-carbons. There was a factory, he believed at Poole, where they used to make a considerable amount of paraffin wax from this material. He would like to know if it were possible to apply gas to a Diesel engine. It would be a simple matter to compress gas and use it as a fuel in the engine, and spray it in with air in the same way as was done with the oil.

The author desired to reserve his reply for publication in the *Journal*.

It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.

SUMMARY

A letter from Mr. A. M. Taylor comments on Mr. Pfeiffer's suggestions for the use of Diesel engines in sub-stations, and defends the use of batteries in this connection. Mr. E. W. Cowan makes some proposals regarding the conduct of discussions at the Institution of Electrical Engineers. (Page 479.)

A patent taken out by Mr. G. Wilkinson for improvements in his live steam feed-water heater was opposed on the ground of anticipation in a previous patent, but the Comptroller, after hearing evidence, has dismissed the opposition. The improvements relate to means of rendering a feed-water heater adjustable to varying conditions of pressure, rate of working of boiler, and initial temperature of feed water. (Page 480.)

On Thursday last the staff of the National Telephone Co. held their fifteenth annual dinner in London, and the opportunity was taken for the expression of the views of the staff and the directors on the pending transfer of the undertaking to the General Post Office. No definite decision had yet been arrived at to advance the date of transfer, nor could any fresh information be given as to the future of the constructional staff. (Page 480.)

At last Thursday's meeting of the Institution of Electrical Engineers, after the business of the annual general meeting had been transacted, Mr. Mordey, the retiring President, read a short Paper on condensers, in which he gave the results of measurements of the losses of two patterns of condenser and alluded to the way in which condensers had been successfully used in the case of the G.B. surface-contact system to prevent the formation of arcs at the stud contacts. Some striking experiments on this point were shown, and a short discussion followed. (Page 481.)

A movement has been initiated by the American Bureau of Standards for securing uniformity in photometric units. For the future the standard candle-power of the United States is to have a value reduced by 1·6 per cent. of its former value, and sensibly equal to the pentane candle and bougie decimale of Great Britain and France respectively. Careful tests have established that the German Hefner unit has a value

Digitized by Google

of 0·9 of the new unit, for which the name "international candle" is suggested. (Page 482.)

A MATHEMATICAL Paper on the theory of the alternator was read recently before the Physical Society by Prof. Lyle. (Page 482.)

MR. C. H. MERZ has been appointed to report on a scheme for the electrification of the Buenos Ayres railways. (Page 482.)

WE are able to publish full technical particulars and sections of the new submarine telegraph cables recently laid between Victoria and Tasmania by Messrs. Siemens Brothers & Co., Ltd. (Page 483.)

THE appeal by the British Westinghouse Co. and Messrs. Körting & Mathiesen, against the decision of the Comptroller-General of Patents to revoke the Bremer and Högner flame arc lamp patents respectively under Section 27 of the new Act has been successful. The proceedings were suspended in March in order that fresh evidence could be put in by the Westinghouse Co., the owners of the Bremer patent. This evidence is to the effect that considerable trouble and expense has been gone to in the efforts to establish the manufacture of the lamps in this country. On the other hand, Mr. Braulik, the applicant for revocation, asserted that he intended to manufacture in this country, that he had applied for a licence under the Bremer patent, but could only have obtained it by paying a higher royalty than Messrs. Körting & Mathiesen. It was urged that there was no true competition between the Westinghouse Co. and the Union Electric Co., as by the agreement the former Company could not undersell the latter. In giving his decision on Tuesday against the revocation of the patents, Mr. Justice Parker upheld the contention of the Westinghouse Co. that satisfactory reasons had existed for their not having been able to manufacture the lamps to an adequate extent in this country. He ruled that each side should pay its own costs, and that the costs of the Attorney-General should be divided between the parties, Mr. Braulik paying half on the case with respect to both patents, the other half being borne by the Westinghouse Co. and Messrs. Körting and Mathiesen respectively. (Page 484.)

THE Folkestone, Sandgate and Hythe Tramways Bill, which proposed to instal the overhead trolley system instead of a surface-contact system, was rejected by a Committee of the House of Commons on Tuesday, so far as the change of systems is concerned. The extension of the Central London Railway to Liverpool Street has been sanctioned. (Page 487.)

ON Tuesday judgment was given in an action brought by Mr. C. A. Gould, of the Gould Storage Battery Co., of America, against Dr. E. H. Lehwess, of the London Electrobus Co., to recover £3,200, the price of batteries, &c., supplied. The judge considered that Dr. Lehwess had misled Mr. Gould with respect to the amount of money to the credit of the English Gould Storage Battery Co., and had prevented the making of certain tests, on the satisfactory conclusion of which the batteries were to have been paid for. Mr. Gould was allowed £2,528 15s. damages, and costs. (Page 488.)

IN spite of the protests of local electrical contractors, the Aberdeen Corporation have decided to let out electric heating and cooking apparatus on the hire-purchase system.—The Acton Council have passed a resolution agreeing to lease their electrical undertaking to the Metropolitan Electric Supply Co. upon certain conditions.—It is proposed to spend £1,800,000 upon tramway extensions in the County of London during the coming financial year.—The Great Northern and City Railway Co. have offered a bulk supply of electricity to the Islington Borough Council.—The Marylebone Council have decided to defray, out of revenue, the cost of the street lighting scheme, sanction for a loan for which was refused by the L.C.C.—A syndicate is being formed to construct an electric monorail from Johannesburg to Pretoria. (Page 488.)

LOCAL GOVERNMENT BOARD loans have been, or shortly will be, held as follows:—Ashton-under-Lyne, £48,000; Bray, £2,600; Aberdare, £17,000. A motor generator and switchgear are required at Dudley; Diesel engines at Gillingham; steam engines, dynamos, &c., by the Leigh and Atherton Joint Sewerage Board; steam piping by the London County Council; and mains at Southampton and Tunbridge Wells. (Page 490.)

AT the annual meeting of the British Westinghouse Co. the deputy chairman, Mr. J. Annan Bryce, expressed the opinion that the electrical industry in Great Britain would never be on a sound footing until the advantages of standardisation were better appreciated. (Page 491.)

THE Annual Report submitted to the annual general meeting of the Institution of Electrical Engineers last Thursday records a slight increase in the total membership, which now stands at 6,097. Announcements were made of the awards of premiums and scholarships, and it was stated that the Institution would be transferred to its new quarters on the Embankment in the autumn, and that the enlarged lecture theatre would be available early next year. Among the donations to the Benevolent Fund is one of £105 from Mr. W. B. Esson. (Page 493.)

ON May 15th the National Telephone Co. transferred the subscribers to its Dalston (London) and its Rusholme (Manchester) exchanges to the C.B. equipment. (Page 493.)

WE are now able to publish the contents of Mr. Mordey's last report on the G.B. surface-contact system on the L.C.C. Tramways, in which all the defects pointed out by the Chief Officer of Tramways are dealt with one by one. Mr. Mordey again says that his investigations have revealed nothing that was not obviously capable of easy remedy. (Page 495.)

SIR W. RAMSAY has taken out a patent for a process of concentrating the oxides of nitrogen produced by passing air through an electric arc furnace. The gaseous mixture containing the oxides is liquefied, and by a continuous process the oxides are separated out in liquid oxygen. When the oxygen contains a large enough percentage of oxides, it is evaporated, the gases being passed through water or an alkaline solution to form nitric acid or a nitrate.—A multiple carbon arc lamp, with a separate clock mechanism for each pair of carbons and means for successively releasing these, is described in a specification by C. A. Carpenter and O. T. Banks; another, by A. D. Jones, relates to carbons for flame arc lamps, in which the chemicals are pasted into grooves and held in by projections of the carbon.—A specification by Dr. Kuzel describes a process of manufacturing metal filaments from colloidal mixtures, by which the production of cavities in the filaments is avoided. The heating and reduction of the filaments to the normal metallic condition is performed in a flowing stream of an inert gas at a very low pressure. (Page 496.)

A PAPER on the electric driving of non-reversing rolling mills was read recently before the Leeds Section of the Institution of Electrical Engineers, in which figures were given relating to several cases where great economy had been effected by changing over to electric drive. (Page 497.)

Mr. J. A. ROBERTSON'S Paper on combined dust destructors and electricity works, originally read at Glasgow, was discussed recently before the Dublin section of the Institution of Electrical Engineers, and several engineers to destructor stations gave their experiences. (Page 498.)

THE appeal in the first electrical case under the revocation clause of the new Patent Act has now been decided, with the result that the Comptroller's decision has been reversed, and the two patents relating to flame arc lamps have been upheld. This result will generally, we think, meet with approval in the arc lighting industry in this country, for the revocation of the patents in question would rather have assisted the importation of foreign-made arc lamps, with consequent cutting of prices, instead of protecting the home industry. The majority of the leading British makers of arc lamps allege that their lamps are not made in accordance with either the Bremer or Högner patent, and the lamps threatened as infringements of the Bremer patent have been for the most part imported ones. There is no doubt that the Westinghouse Co., in taking up the Bremer patent, made the first steps towards introducing the highly-efficient flame arc lamp which has practically revolutionised electric street lighting, and that at the same time the Union Electric Co., who are licensees under this patent, and whose principals are owners of the Högner patent, took the most prominent part in extending the use of the flame lamp all over the country. It is satisfactory, therefore, that these two firms should continue to derive a fair reward for their enterprise. The case is on an entirely different basis from the one which the revocation clause in the new Patents Act was designed to meet, namely, that of a foreign manufacturer who uses his British patent solely to create a monopoly for foreign-made articles in the British market.

ARRANGEMENTS FOR THE WEEK

THURSDAY, JUNE 3RD.

Royal Institution.

3 p.m. Afternoon Lecture I., by Prof. W. E. Dalby, on "A Modern Railway Problem: Steam *v.* Electricity."

Röntgen Society.

8.15 p.m. Annual General Meeting at 20 Hanover Square, London, W. Mr. R. S. Wright will show and explain the new "Snook" Röntgen apparatus.

FRIDAY, JUNE 4TH.

Royal Institution.

9 p.m. Evening discourse by Prof. J. A. Fleming, F.R.S., on "Researches in Radiotelegraphy."

CORRESPONDENCE

OIL ENGINES FOR USE IN SUB-STATIONS.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—Mr. Pfeiffer's proposals for the use of oil engines in sub-stations will not, I feel sure, meet with the assent of the majority of central-station engineers who have to run a central station in conjunction with sub-stations. The proposals put forward are really too radical in their nature to cause them to be looked upon with favour. It is quite too alarming to think of the tremendous changes that would be involved by decentralising the main stations, and breaking the links between the sub-station and the main station. If the oil engine is as economical as claimed, let it, by all means, be put in at the central station, but don't break the links between the main station and the sub-stations.

It has hitherto been an accepted principle the world over, that the greater the amount of plant that can be centralised in one station, the lower will be the fixed charges for wages and supervision. When to this is added the lower capital cost per kw. of the larger generating plant, a further advantage is obtained. It is also a fact that the smaller the proportion which the cost of the fuel bears to the other charges making up the cost at the sub-station, the greater does the saving become that is effected by centralisation under the above two items.

The cost of the sub-station plant is so low, by comparison with the main plant, that it can be thrown in, with still a considerable advantage in favour of centralisation. This sub-station plant, moreover, being all operated from the sub-station switchboard, attendance on same is reduced to a minimum, and wages charges are correspondingly low, even on sub-stations very much smaller than Mr. Pfeiffer has considered. Then, again, the cost of the high-tension feeders between the main station and the sub-stations will, in most large towns, be found to be only of the order of £2 per kw., instead of the £8 taken by Mr. Pfeiffer.

If accumulators are introduced in the sub-stations several further advantages are gained: (1) The generating plant at the main station can be used to give 30 to 40 per cent. more output; (2) the wages and other fixed charges consequent upon not putting down that extra plant are in large measure saved; (3) a stand-by *instantaneously* available for the generating station and for each of the sub-stations is provided.

When these advantages are tacked on to those of centralisation, it will be seen how much we are asked to give up by the employment of oil engines in sub-stations, let alone the poor overload capacity of the oil engine, which is a most serious disadvantage when used under such conditions.

Yours faithfully,

A. M. TAYLOR.

King's Heath, Birmingham.
May 23rd, 1909.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—It may be of profit, as the current session of the Institution of Electrical Engineers is now drawing to a close, to take some stock of the position in the light of a review of the proceedings at the general meetings now terminated. We have had many good Papers, but I venture to question whether we have complemented the value of these contributions by bringing to bear upon them the best criticism which the knowledge and experience of the general body of members renders potentially available. Are there not "ungotten minerals" which a means ought to be found of extracting for the further enrichment of our discussions? With this end in view I submit a few suggestions in the direction of some alteration in the method of conducting these discussions.

Might not all members desiring to take part in a discussion be required, when sending their names, to submit a very brief summary of, or at least the heads of, their proposed contribution? The president, having a list before him of the points which will be dealt with by each speaker, can "edit" the debate with due regard to the relative importance of the matter contributed rather than to his estimate of the importance of the matter which the speaker is capable of contributing. Thus interesting, but digressive discourse, may be curtailed, and time found for valuable contributions, some of which, though tendered, remained "ungotten" (to my knowledge) during the last session. Of course these contributions can always be sent to the Journal, but there is not the same point in swelling the minutes of proceedings with matter which did not form part of those proceedings, and the inducement is often an insufficient incentive to excite the effort.

Instead of the author's reply being relegated to a few breathless minutes at or after closing time, might not an opportunity be given to him of replying at reasonable length to all the points of criticism which lend themselves to verbal treatment? The meeting wants to hear the author's defence. Debate has lost its best characteristic when criticism is not met with prompt reply.

When Papers lend themselves to such treatment, might not the discussion of them be taken "by compartments"? The author or the editing committee could settle the divisions, and the president would introduce them to the meeting in the order of their importance. With such an arrangement much confusion would be avoided, and, when time pressed, the points of relative unimportance would be crowded out instead of persons of relative unimportance. A progressive change. There would also be a great advantage from a "debate" point of view, if at least a few minutes were reserved for general discussion as distinct from the contributions of those who have sent in their names, and if the author was given an opportunity of replying on each point before the next one was presented for discussion.

The above suggestions are not made in any spirit of criticism, but purely with a view to a possible improvement of what is already good.

I am, yours, &c.,

EDWARD W. COWAN.

4 Queen Victoria Street, E.C.
May 25th, 1909.

St. Petersburg Tramways.—In connection with the proposed sale of the tramway undertaking by the Municipality, a petition for the granting of a concession for the construction and operation of the new lines has been submitted. The concessionaire proposes to purchase the existing power-house, sub-stations, and cable system, and to supply the existing section of the tramway system, which will remain under the control of the city, with power at stipulated prices. The Tramway Committee are favourable to the scheme, but have reduced the price at which the power is to be supplied for the existing section. The concession is to extend over a period of 40 years. Through running between the new sections and the existing section will be arranged for if the scheme is accepted.

THE WILKINSON FEED WATER HEATER

THE Comptroller of Patents has just given his decision in the matter of an opposition to the grant of a patent to Mr. George Wilkinson, of Harrogate, for improvements in the "Wilkinson" feed water heater, which was fully described and illustrated in ELECTRICAL ENGINEERING of August 22nd, 1907, vol. ii., p. 301. There are a series of patents for this heater, and the present application, No. 1,777 of 1908, relates to means for regulating the amount of heat transferred from the steam to the feed-water.

It has been found that in live steam heating there is a most economical value for the proportion of heat units transferred from the steam in a boiler to the feed water brought in contact with it. The point of maximum efficiency depends on the type of boiler, the rapidity of circulation of water in the boiler, the initial temperature of the feed water, the rate of evaporation, and the steam pressure. The purpose of this invention is to make the capacity of a live steam heater adjustable to suit varying conditions, and is especially advantageous where the feed water has a low initial temperature. The adjustment is attained by varying (*a*) the surface contact between the steam and feed water; (*b*) the time during which the steam and water are in contact; and (*c*) the proportion of feed water heated. The last-mentioned method, it is said, is the easiest and simplest to carry out, as valves, operated automatically or otherwise, can be arranged to regulate the relative proportion of feed water passed through the heater.

The grant of the patent was opposed by Messrs. Hamilton & McMasters, of the Central Engine Works, Belfast, on the ground that the invention had been patented under their prior patent No. 21,070 of 1900, and also upon the ground that the manner in which Mr. Wilkinson's invention was to be performed was not sufficiently or fairly described and ascertained in his complete specification. The opposition having been argued at a hearing before the Comptroller, at which the applicant was represented by Messrs. Tasker & Crossley, Patent Agents, Halifax, and the opponents by Messrs. Marks & Clerk, of London, the opposition was dismissed with seven guineas costs against the opponents.

THE NATIONAL TELEPHONE COMPANY

Speeches at the Annual Staff Dinner

ON Thursday last the staff of the National Telephone Co. held their fifteenth annual dinner at the Trocadero Restaurant, London, with Mr. Albert Anns, the secretary of the company, in the chair. The gathering, numbering over 300, consisted of the chief officials of the company in the United Kingdom, representing a staff of upwards of 17,600, and guests including Mr. George Franklin (president of the company), Sir H. Babington Smith (representing the Post Office), Mr. Frank Gill (engineer-in-chief), Mr. S. J. Goddard (general superintendent), Sir Robert Hunter, Sir John Gavey, Major O'Meara, and many others. Some interesting speeches were delivered, and an excellent musical programme had been arranged.

Mr. ALBERT ANNS, in proposing the toast of "The Company," stated that there had not been any striking progress within the last 12 months owing to the limitation of capital expenditure. In the past year, 88 new exchanges had been opened and 53,756 stations had been connected; as 26,180 had been disconnected, however, the net increase was only 27,576 stations. With regard to the measured rate, it had only been adopted after months of careful consideration, and it was a surprise to the directors that so much opposition had been shown. By upholding this innovation, Mr. Buxton had ensured the telephone being a commercial asset to the nation. He estimated the value of the telephone system at 20 million pounds. As to the future of the staff, the agreement of 1905 was fair to the shareholders but not to the staff; the directors and manager had fought for the staff, and he was sure that arrangements would be made to avoid bringing on the staff a wholly unmerited punishment. They had, he knew, the sympathy and support of the officials, and the fact that Mr. Buxton was so highly esteemed by the Post Office department augured well for their fair treatment in the future. The present might be the last of these annual gatherings, as the date of transfer might be advanced. Finally, Mr. Anns proposed the toast of the National Telephone Co. coupled with the name of the president, Mr. George Franklin.

Mr. GEORGE FRANKLIN, in responding to this toast, said he would have hesitated to put a value on the undertaking anything near that stated by Mr. Anns. He thought that the less said about the 1905 agreement the better. The development of the company within the last seven years had been remarkable. The royalty paid to the Postmaster-General last year was £283,000, and since the beginning a sum of £2,825,000 had been paid. The number of calls had increased by 9½ million over the figure for the previous year. The total cost of each call worked out at 0·49d. Tests had been made in London as to the rapidity of the service; as a result it was found that the average time elapsing between a call and the answer from the exchange was 4·7 seconds, and the time from the call to the placing of the called subscriber on the line 38 seconds. Tests in other towns showed the latter figure to vary between 22 and 45 seconds. With regard to the line plant, 71·3 per cent. of the lines were underground, and 28·7 per cent. overhead. The number of central battery exchanges now numbered 26·6 per cent. of the total; six had been opened since January 1st of this year, and there were twenty-six nearing completion. The number of stations in London had increased from 1 to every 137 inhabitants in 1903, to 1 to every 78 in the present year. He thought that the measured rate policy would be found the only practicable solution, and would be universally adopted; the flat rate stood in the way of the development of the service. Referring to the natural anxiety of the staff as to the effect of the transfer, he said that he had no secrets to divulge. He asked the staff to have confidence in and to trust the directors, who recognised the necessity of seeing that no injustice should fall on any member of the staff.

The toast of "Our Guests" was proposed by Mr. WILLIAM E. HART, the solicitor to the company, who especially welcomed the representatives of the Post Office under whose influence the staff would soon come.

Sir H. BABINGTON SMITH, replying to this toast, delivered a message from Mr. Buxton, the Postmaster-General, who regretted that he had not been able to attend. Sir Babington Smith referred to the past influence of the Post Office on the development of the company, suggesting that this had had a beneficial effect. The telephone undertaking had a great future before it, and there would be full scope for all the ability and energy in the combined undertaking that had been shown in the separate concerns. The staff could be confident that they would not meet with any injustice. Difficulties that arose in the transfer of such a large undertaking were inevitable.

The toast of "The Guests" was also responded to by Mr. W. ALEXANDER SMITH, who reminded the staff that the first gathering took place in Glasgow twenty-five years ago next November.

The last toast on the list was that of "Engineering," and was proposed by Mr. FRANK GILL (Engineer-in-Chief to the company), who referred to the fact that there was a larger proportion of civil engineering than electrical engineering in telephone work. After making appreciative references to the work of Mr. Duddell and others, and emphasising the difficulties of dealing with very small quantities of energy, he pointed out that the energy used in a trunk conversation was so small that it would take sixteen million such conversations to equal the energy consumed by a 16-c.p. lamp. He estimated that the cost of "speech current" came out at £16,400 per unit. There were, he estimated, over ten million telephones in use in the world, and some £350,000,000 of capital invested in telephone systems.

Mr. W. M. MORDEY, in replying to this toast, mentioned that he thought he had made one of the first telephones in this country, namely, when, in about 1877, he made one from a description cabled over from America. He had assisted Graham Bell in his demonstrations in this country. There had, he thought, been too much tendency to raise barriers between the different branches of the electrical engineering industry. The technical connection between heavy electrical engineering and telephone work was close, and each owed the other much. Thus he had been working on the improvement of the Hadfield steels for magnetic purposes, and although this had been done for the purposes of heavy work, it had been found that a distinct improvement was obtained by using this steel in telephonic apparatus. Again, Mr. S. G. Brown, by applying knowledge obtained from heavy work, to telegraph work, had developed his wonderful relay, for the use of which, he understood, one company was paying a royalty of £7,000 per annum. Finally, Mr. Mordey emphasised the fact that engineers should have broad views, and should keep thoroughly acquainted with the branches of their profession other than that in which they were actually engaged themselves.

Alleged Death from Electric Shock on Tramcar.—At an inquest on Monday, at Sedgeley, into the death of Benjamin Cole, who was found dead on the top of an electric tramcar, it was suggested that death may have been due to electric shock. The coroner adjourned the inquest in order to communicate with the Board of Trade on the subject.

East London College.—Prof. J. T. Morris will give a lecture on Monday, June 7th, at 8 p.m., at the East London College, Mile End Road, on "The Technical Aspect of the G.B. System of Electric Tramways." The chair will be taken by Mr. W. H. Patchell. The lecture arrangements at the college also include a course of three lectures by Mr. L. Murphy on "Electrification of Main Lines." Mr. Phillip Dawson is to take the chair at the first lecture.

COUNTY BOROUGH OF WEST HAM.

APPOINTMENT OF
ELECTRICAL ENGINEER AND MANAGER.

THE COUNCIL of the COUNTY BOROUGH of WEST HAM invite applications for the Post of ELECTRICAL ENGINEER and MANAGER of their ELECTRICITY UNDERTAKING.

Candidates must have had considerable experience in important Electricity Undertakings, and have a sound knowledge of the commercial management of Electricity Supply.

The successful candidate will be required to give the whole of his time to the conduct of the business. The present salary attaching to the post is £500 per annum, but this need not be regarded as the limit the Council would be willing to pay, and they therefore invite applicants to state salary required, age, full particulars of experience, and when duties could be commenced.

Application forms and any other particulars required may be obtained on application to the undersigned. Canvassing is strictly prohibited.

Applications must reach me not later than 5 p.m. on Tuesday, 1st June next.

FRED. E. HILLEARY,
Town Clerk.

Town Hall, West Ham,
12th May, 1909.

HERIOT WATT COLLEGE, EDINBURGH.

DEPARTMENT OF ELECTRICAL ENGINEERING.

THE GOVERNORS invite applications for the post of Assistant Lecturer in Electrical Engineering, the duties to commence 6th September. Salary £130 per annum. Further information may be obtained from Professor Baily at the College. Applications and copies of testimonials to be lodged with the Principal of the College on or before 21st June.

METROPOLITAN BOROUGH OF STEPNEY.

ELECTRICITY SUPPLY.

METERS, DEMAND INDICATORS, TIME SWITCHES AND CARBONS.

THE ELECTRICITY SUPPLY COMMITTEE of the STEPNEY BOROUGH COUNCIL invite tenders for the supply, during the period ending 30th June, 1911, of:—

(1) Ampere-Hour Meters, Demand Indicators and Time Switches.

(2) Arc Lamp Carbons.

Specifications, General Conditions and Forms of Tender may be obtained on application to W. C. P. Tapper, A.M.I.E.E., the Borough Electrical Engineer and Manager, at 27, Osborn Street, Whitechapel, E., on payment of a deposit of One Guinea for each of the Specifications Nos. 1 and 2, which will be refunded to *bona-fide* Tenderers after the Tenders have been adjudicated upon. Additional copies will be charged for at 5/- each, which will not be returned. Copies of the specifications may also be seen at any time by application at 27, Osborn Street, aforesaid.

Tenders must be delivered at 27, Osborn Street, not later than noon on June 14th, 1909, signed, sealed and marked "Tender for Carbons," "Meters," "Demand Indicators," or "Time Switches," as the case may be.

The Council do not bind themselves to accept the lowest or any tender.

GEO. W. CLARKE,
Town Clerk.

Municipal Offices,
15, Great Alie Street,
Whitechapel, E.
19th May, 1909.

ELECTRICAL ENGINEER (29), seven years' experience meter testing, switchboard instruments, office, requires change. Salary 35/- commencing. Box A 78, ELECTRICAL ENGINEERING, 203, Temple Chambers, London, E.C.

COUNTY BOROUGH OF SOUTHAMPTON.

CABLES, ELECTRICITY DEPARTMENT.

THE CORPORATION invite tenders for the supply of sundry heavy cables for low-tension trunk mains required by the Electricity Department in accordance with specification, particulars and conditions which may be obtained, with forms of tender, of the Borough Electrical Engineer, Mr. H. F. Street.

Sealed tenders in the prescribed form, endorsed "Tender for Cables," must be delivered at the Town Clerk's Office by the time specified in the form of tender.

No pledge is given to accept the lowest or any tender.

R. R. LINTHORNE,
Town Clerk.

Town Clerk's Office,
Municipal Offices, Southampton.
19th May, 1909.

COUNTY OF LONDON.

THE LONDON COUNTY COUNCIL invites tenders for the undermentioned work at the Greenwich electricity generating station:—

(*a*) The supplying and fixing of steam, exhaust, feed and drain piping, valves, &c.

(*b*) The supplying and fixing of cast-iron condenser water piping, valves, &c.

Full particulars and also information as to the conditions to be observed by tenderers will be given in the *London County Council Gazette* of 31st May, 1909. The Gazette, which is published weekly, contains particulars of all the tenders invited by the Council, and can be obtained from Messrs. P. S. King & Sons, 2 and 4, Great Smith Street, Westminster, S.W., price 1*d.*, post free 1½*d.*, an issue, or for the whole year a prepaid subscription of 6*s.* 6*d.*

Tenders must be upon the official forms to be obtained from the Clerk of the Council, at the County Hall, Spring Gardens, S.W., upon payment to the Cashier of the Council, of the sum of £2 for each specification, &c. This deposit fee will only be returned if a *bona-fide* tender is submitted. No tender received after 11 a.m. on Tuesday, 22nd of June, 1909, will be considered.

The Council does not bind itself to accept the lowest or any tender, and it will not accept the tender of any person or firm who shall on any previous occasion have withdrawn a tender after the same had been opened, unless the reasons for the withdrawal were satisfactory to the Council.

G. L. GOMME,
Clerk of the London County Council.

County Hall,
Spring Gardens, S.W.
24th May, 1909.

DUNDEE CORPORATION ELECTRICITY DEPARTMENT.

FOR SALE:—TWO CONTINUOUS CURRENT ELECTRIC GENERATING SETS complete, consisting of Willans Engines and Siemens Dynamo. Output 360 amperes at 250 volts at 350 revs. per minute.

FOUR LANCASHIRE STEEL BOILERS 24 ft. long by 7 ft. diameter, working pressure 160 lbs. to the sq. inch, with fittings and mountings complete.

Full particulars may be had on application to the undersigned, to whom the offers are to be addressed and delivered.

The highest or any offer will not necessarily be accepted.

H. RICHARDSON, M.I.E.E., M.I.Mech.E.,
City Electrical Engineer.

Dudhope Crescent Road,
Dundee.
May 25th, 1909.

Preliminary Announcement.

LOCKSBROOK ENGINEERING WORKS
(KRAMOS, Ltd.).

Sale of Electrical Engineering Plant and Stock.

FORTT, HATT & BILLINGS
Have received Instructions
To SELL by AUCTION, upon the Premises,
On TUESDAY, JUNE 15th, 1909, at 11 o'clock precisely.

THE LEASE; GOODWILL; PATENTS; PATTERNS; DRAWINGS; WORKING PLANT and STOCK of the above Company; fuller details of which will appear in future Announcements.

The above will first be offered as a Whole, and if not then disposed of, will be sold in Lots.

Catalogues are in course of preparation, and may be had of
Messrs. HAM, DENNEHY & CO.,
Chartered Accountants, Quiet Street, Bath;
Or of the AUCTIONEERS, at their Estate Agency Offices, 3, Burton Street, Bath.

GAS RETORT CARBON for Sale. Pitch, Insulating Material, Creosote. We supply the Trade.—V. Dasnieres, 10, St. Mary Axe, London, E.C.

NOTICE.

READERS OF "ELECTRICAL ENGINEERING" who do not have their copies posted to them direct from the Publishers, are particularly requested to communicate with us, if they do not obtain the paper regularly and punctually. We are desirous that ALL readers should have their "Electrical Engineering" at the earliest moment that it is possible to get a copy to their locality, and upon receiving any complaints, we will take steps to ensure a prompt supply.

The KILOWATT PUBLISHING CO., Ltd., Publishers,
203-6, Temple Chambers, London, E.C.

GREAT EDUCATION SCHEME.

GENERAL ELECTRICAL ENGINEERING taught in twenty Lessons. Instruction and Examination by Post 1/- per Lesson. Student's verdict:—"No quicker method of gaining the desired information . . . as they contain the best relating to Practical Electrical Engineering." Send for free Syllabus, to The Science and Art of Mining, Office, Dept. D., Wigan Lancs.

GENUINE VULCANISED FIBRE SHEETS, RODS, TUBES, GEAR WHEELS, INSULATORS, WASHERS, &c.

MOSSES & MITCHELL, 122 & 124 GOLDEN LANE, LONDON, E.C.

John E. Raworth,
Queen Anne's Chambers, Chartered Patent Agent,
30, Broadway, Westminster, London, S.W.

BINDING VOLUME IV. OF "ELECTRICAL ENGINEERING"
JUNE to DECEMBER, 1908.

Subscribers' Numbers, sent to us Carriage Paid, will be bound in strong dark red Art Linen, with strengthened corners and back, and returned to any address in the United Kingdom, Carriage Paid, for 4s. 6d. Binding Cases only, 2s. each, or 2s. 4d. by post.

Volumes for the Colonies and Abroad will be sent Carriage Forward.

The Kilowatt Publishing Co., Ltd.
203-206, Temple Chambers
London, E.C.

HIGH TENSION CONDENSERS

MOSCICKI TYPE.

These are the only Practical Condensers for High Tension which are available at the present time. (See Paper by Mr. W. M. Mordey, President of the Institution of Electrical Engineers.)

Used for **POWER FACTOR IMPROVEMENT**
PROTECTION OF OVERHEAD LINES
RADIO-TELEGRAPHY

OVER 30,000 IN ACTUAL OPERATION.

We invite Enquiries, stating full details of problems to be dealt with.

ISENTHAL & CO.,

TESTS AND USES OF CONDENSERS

AT last Thursday's meeting of the Institution of Electrical Engineers, Mr. W. M. Mordey read a Paper entitled, "Some Tests and Uses of Condensers." The main object of the Paper was to describe some investigations which had been made into the properties of condensers in another connection, but the opportunity was taken to consider to what extent they might be considered suitable for use on alternate-current systems.

Two patterns of condensers only were considered, *viz.*, paper condensers of the kind described by Mr. Mansbridge before the Institution last year (see ELECTRICAL ENGINEERING, Vol. III., page 741), and the Moscicki type of glass condenser.

The former are made, by a continuous process, of paper coated on one side with a thin metal layer, and have the advantage that if they are pierced they are self-healing, the metal being vapourised so as to produce a space clear of metal round the fault.

The Moscicki condenser was described and illustrated in ELECTRICAL ENGINEERING, Vol. I., page 565, and its use for the improvement of power factor was discussed in an article in ELECTRICAL ENGINEERING, Vol. II., page 57. Each unit of a battery of these condensers consists of a specially-formed glass tube closed at one end and coated inside with silver deposited chemically, and immersed in another tube filled with a mixture of glycerine and water. The chief point in their construction is that the glass, although thin enough throughout the main portion to give considerable capacity, is thickened at the edge of the coating at the neck, where rupture is most liable to take place.

Mr. Mordey had a number of tests made at the Westminster Testing Laboratory with a view to determining the losses with both these patterns, and some results were given in the form of curves in the Paper. A 10-microfarad Mansbridge condenser made for pressures up to 600 volts was found to have a nearly constant power factor between 0·0055 and 0·006 at all frequencies from 25 to 75 cycles. The energy lost varied from about 0·25 watt per microfarad at 500 volts 25 cycles to about 0·65 watt at 75 cycles, with much lower values, also sensibly proportional to the frequencies at lower voltages; for example, at 200 volts 75 cycles the figure is 0·1 watts per microfarad. The measurements were made with a reflecting wattmeter. Although at present only made up to 500 volts, it is suggested by one of the firms who manufacture them that they may be employed up to, say, 10,000 volts by placing a number in series, and that a condenser so arranged would cost about £27 per microfarad.

The Moscicki condenser tested consisted of 8 tubes, each 2 in. diam. and 2 ft. 9 in. long, having a total capacity of 0·03 microfarad. This was tested at various voltages up to 10,000 volts, and gave a power factor of about 0·010, and a loss of about 320 watts per microfarad at 10,000 volts, and about 80 watts per microfarad at 5,000 volts. A battery of ordinary Leyden jars tested at the same time gave slightly higher values, especially at the higher voltages. Roughly speaking, the losses in the Moscicki condensers appear to be proportional to the square of the voltage, and directly to the frequency. Further tests were made with the assistance of a 10,000-volt secondary battery belonging to Mr. Campbell Swinton, showing the improvement of insulation resistance with continued electrification, and showing incidentally that the C^2R losses are negligible. Thus the losses in the two types tested are shown to be, under ordinary conditions, about 0·6 and 1 per cent. respectively of the k.v.a. dealt with.

With regard to the improvement of power factor, Mr. Mordey remarked that in sub-station work, where motor-generators or rotary converters were used, or industrial work where synchronous motors were used, it should always be possible to arrange by over-excitation to provide a considerable amount of power-factor correction at a small increase in the cost of the machinery. But there were many conditions in alternate-current supply where self-induction could not be compensated in this way.

He then proceeded to investigate a case where it is desired to change the power factor of a 1,000-kw., 10,000-volt, 50-cycle load from 0·8 to unity, and arrived at the following figures :—

	Synchronous Motor.	Condenser.
Capital cost	£1,100	£720
Annual cost of energy wasted ...	£137	£ 32·2

In these figures no attempt was made to compare the cost of condensers with the added cost necessary to make ordinary motors or rotary converters available for power-factor correction in addition to their ordinary work, but the low capital and working cost of the condensers, said Mr. Mordey, pointed to a comparison, even on this basis, being possibly favourable to the latter.

In conclusion, the author drew attention to the result of some experiments on the use of condensers for preventing or stopping the formation of arcs under certain conditions. In investigating the action in a surface-contact tramway system recently, the author found that trouble was experienced due to the formation of persistent arcs at the underground contacts. When the road was wet and dirty a small leakage current passed from the live contact stud under the car over the surface of the road to the rails. When the car had passed and the underground contact-piece had separated its proper distance from the live conductor, this leakage current was sufficient to maintain an arc across the air-space of the contact-maker, thus keeping the stud alive so long as the arc persisted. It was found that with a terminal voltage of about 560 volts the voltage between the stud and the rail was usually about 400 to 440 volts, and the voltage across the arc about 120 to 160 volts. Sometimes arcs would persist for a few seconds with not more than 0·6 ampere, and they would often persist when the leakage current was over 1 ampere—this latter condition, it will be seen, corresponds to a resistance of the leakage path from the stud to the rail of a maximum of 440 ohms. The prevention of these arcs by increase of gap, or by other structural alterations, was not found to be practicable, and it therefore remained to try to find some means for preventing their formation, or for immediately putting them out if they were formed. For this purpose experiments were made with a condenser, which was found to be quite effective.

It was found quite practicable to extinguish the arcs by shunting them by a condenser carried on the car, one terminal being connected to the collector or skate, the other to a small wire brush hanging down under the rear platform of the car, and making successive contacts with the studs. It was also found that the arcs could be put out by placing the condenser in shunt across the leakage path instead of across the arc itself, or with two condensers in series across the resistance and the arc, with a middle connection to the junction between them. It was not necessary that the condenser should be in a discharged condition, the arc being put out, whether the condenser when applied was discharged, or when it was charged to the full voltage of the circuit, in which latter case the effect would be produced in whichever direction of polarity the condenser was applied.

After reading the Paper, Mr. Mordey showed a few very striking experiments which demonstrated the very marked effect of the connecting up of a suitable condenser in extinguishing and in preventing the striking of an arc.

DISCUSSION.

Mr. G. F. MANSBRIDGE thought that the manufacture of condensers for high-tension work was purely a question of supply and demand. At present the British Insulated and Helsby Cables, Ltd., and other firms were making low-tension condensers by the thousand, and owing to the few orders for high-tension condensers it did not pay to put in special machinery for their manufacture. Therefore low-tension condensers were connected in series for the purpose. There were, however, objections to having high pressure across even a pile of condensers when equally good results could be obtained by putting in a transformer and running at lower pressures. The C^2R losses spoken of by the author were really those depending on the actual insulation resistance of the condensers, but there was also a certain C^2R loss due to the resistance of the electrodes. This was an important point, and at present the Mansbridge condenser was only designed for telegraph and telephone work. But if they were going to be run at full load for anything like twelve hours per day, it would be necessary to put more tin, or, at any rate, a greater number of electrodes, so as to reduce the C^2R loss in the electrodes themselves. With regard to the loss by dielectric hysteresis, there was reason to think that the less the thickness of wax in the condenser, the less would be the dielectric loss, but he was not prepared to make that as a definite statement. The effect of Mr. Mordey's experiment with the arcs, which he had demonstrated, appeared to be directly opposite to that obtained in the Brown cable relay. He believed that Mr. Brown used the condenser to maintain the current across a breaking or doubtful contact, whereas Mr. Mordey used the condenser across the break to ensure the break. It might be remembered that in treating the paper for the Mansbridge condenser it was usual to burn out all the weak spots by passing it in a continuous strip over a metal roller which was connected on one side with 100 volts. There was a rubbing contact on the other side—of the

Digitized by Google

paper, so that whenever a defect passed over the roller there was a momentary arc, and the defect was eliminated. He had found by putting the condenser across, say, the electric lighting mains with plenty of energy behind, there was an appreciable increase, perhaps double or even treble the number of weak spots picked up by that process. He did not think that self-induction was the explanation, because he had put an appreciable resistance in series with the shunted condenser and still got the same effect. He thought this had a bearing on the experiments seen that evening, and also on the Brown relay.

Mr. W. B. ESSON thought the reason why condensers had not been used for power hitherto was their unreliability due to their construction having remained in the hands of the instrument makers. Dynamos were equally unsatisfactory until their construction was taken over by engineers, and the same thing applied to condensers. The Standard Manufacturing Co., of America, at one time supplied two condensers as part of their ordinary equipment for two-phase motors, but he did not know with what success. This showed, however, that the use of condensers in this connection had been appreciated for a long time. The Moscicki condenser, however, was a thorough engineering piece of apparatus; he had seen experiments with it at Freiberg University when the condenser had been running at 6.000 volts for a whole day, and nothing happened. Phase rectifiers or compensating motors had been used with great success on the transmission system of the Kolar Goldfields in India. There they had been very much troubled with lagging currents at the commencement of that undertaking, because they used ordinary three-phase motors. Later they installed synchronous motors, not only for the purpose of compensation, but to do useful work. There were, no doubt, however, instances in which the condenser would be much more convenient, and also cheaper if they could be made reliable.

Mr. J. E. TAYLOR (Assistant Superintending Engineer, G.P.O.) thought there were better methods available for measuring losses in condensers than by the use of wattmeters. The Duddell thermo-ammeter, for instance, lent itself very well to this purpose, for it could be used in such a way that there was no self-induction in the circuit, which was a very important thing in connection with the question of power factor.

Mr. W. M. MORDEY, in reply to Mr. Mansbridge, said that with regard to the C^2R losses in the conductor of the condenser, he thought this was perhaps less important than Mr. Mansbridge supposed. The total losses in the condenser from all causes was $4\frac{1}{2}$ watts, and it was certain that a large proportion of this was dielectric hysteresis, so that the actual possible reduction of the total loss due to an increase in the cross section of the conductor must be very small.

UNIFORMITY IN PHOTOMETRIC STANDARDS

AN important announcement has been made with regard to the photometric units maintained at the Bureau of Standards, America, in Paris, and at the National Physical Laboratory.

In order to determine as accurately as possible the relations between the photometric units of America, France, Germany, and Great Britain, comparisons have been made at different times during the past few years between the unit of light maintained at the Bureau of Standards, Washington; at the Laboratoire Central d'Electricité, Paris; at the Physikalisch-Technische Reichsanstalt, Berlin, and at the National Physical Laboratory, London. The unit of light at the Bureau of Standards has been maintained through the medium of a series of incandescent electric lamps, the values of which were originally intended to be in agreement with the British unit, being made 100/88 times the Hefner unit. The unit of light at the Laboratoire Central is the bougie decimale, which is the twentieth part of the standard defined by the International Conference on Units of 1884, and which is taken, in accordance with the experiments of Violle, as 0·104 of the Carcel lamp. The unit of light at the Physikalisch-Technische Reichsanstalt is that given by the Hefner lamp burning at normal barometric pressure (76 cm.) in an atmosphere containing 8·8 litres of water vapour per cubic metre. The unit of light at the National Physical Laboratory is that given by the 10-c.p. Harcourt pentane lamp, which was prescribed for use by the Metropolitan Gas Referees, burning at normal barometric pressure (76 cm.) in an atmosphere containing 8 litres of water vapour per cubic metre. In addition to the direct intercomparison of flame standards carried out recently by the national laboratories in Europe, one comparison was made in 1906, and two in 1908, between the American and European units, by means of carefully seasoned carbon filament electric standards, and as a result of all the comparisons the following relationships are established between the above units.

The pentane unit has the same value within the errors of experiment as the bougie decimale. It is 1·6 per cent. less than the standard candle of the United States of America, and 11 per cent. greater than the Hefner unit.

In order to come into agreement with Great Britain and France, the Bureau of Standards of America proposed to reduce its standard candle by 1·6 per cent., provided that France and Great Britain would unite with America in maintaining the common value constant, and with the approval of other countries would call it the International candle. The National Physical Laboratory, London, and the Laboratoire Central d'Electricité, Paris, have agreed to adopt this proposal in respect to the photometric standardisation which they undertake, and the date agreed upon for the adoption of the common unit and the change of unit in America was April 1, 1909. The following simple relations therefore hold from that date: The new unit =1 pentane candle, =1 bougie decimale, =1 American candle, = 1·11 Hefner unit, = 0·104 Carcel unit. Therefore 1 Hefner unit = 0·90 of the new unit.

The pentane and other photometric standards in use in America will hereafter be standardised by the Bureau of Standards, in terms of the new unit. This, within the limits of experimental error, will bring the photometric units for both gas and electrical industries in America and Great Britain, and for the electrical industry in France to a single value, and the Hefner unit will be in the simple ratio of 9/10 to this international unit. The proposal to call the common unit of light to be maintained jointly by the national standardising laboratories of America, France, and Great Britain the "International candle," has been submitted to the International Electrotechnical Commission, and through it to all the countries of the world which are represented on that Commission.

We are authorised to state that the agreement described in the above announcement has been arrived at, and has the approval of the Gas Referees, and that the photometric standards of the National Physical Laboratory are being maintained in accordance with it.

THEORY OF THE ALTERNATOR

AT the meeting of the Physical Society on April 23rd, a Paper by Prof. Lyle, entitled, "The Theory of the Alternate-Current Generator," was read. In this Paper the author commenced by giving his opinion that the theory of armature reaction as ordinarily discussed is unsatisfactory, as an important effect due to the mutual induction between the current in the field winding and the current in the armature circuit is neglected. To simplify the problem, the case of a simple ironless single-phase alternator is first discussed. The magnetic field, supposed uniform, is due to the current in a fixed coil connected with a source of constant electromotive force, and the armature is a coil of wire rotated in this field with constant angular velocity. In these circumstances, we may suppose that the mutual inductance between the two circuits varies in accordance with the harmonic law. The author gives a method of getting the complete solution and the differential equations which determine the values of the two currents.

The results prove that only odd harmonics appear in the expression for the armature current, and only even harmonics appear in the expression for the field current. The frequency of the induced ripple superposed on the exciting current is therefore double the fundamental frequency. The interesting fact is proved that this ripple is asymmetric, that is, the positive half of the wave is of a different shape from the negative half. A simple geometrical method of obtaining the solution is also given.

The author next takes into account the effects of hysteresis and eddy currents by means of "permeability operators." The magnetic leakage of the armature is also taken into account. As a practical illustration of the method, the operation of a small two-pole alternator when supplying a non-inductive load is predetermined. A diagram is given showing the exact shape of the current wave in the armature, the ripple superposed on the exciting current, and their relative phase displacement. The action of "dampers" in diminishing the heat-losses in the field circuit, and the theory of the synchronous motor, are also discussed.

Tramways and Telephone Exchanges.—The Board of Trade have appointed Mr. G. L. Macfarlane, K.C., as arbitrator in the case between the Postmaster-General and the Tramways and Light Railways Association on the question whether the cost of fuses and heat coils for the protection of telephone exchange apparatus from the effects of accidental contact with overhead tramway conductors should be borne by the tramway authority or the Post Office. The case selected, as announced in ELECTRICAL ENGINEERING of April 22nd (page 380), is that under the Wemyss Tramway Order.

Railway Electrification in Buenos Ayres.—The question of increasing the carrying capacity of the Buenos Ayres railways has been under consideration for some time, and it is now announced that the Central Argentine Railway, which, since its amalgamation with the Rosario line, carries more passengers in and out of the city than any other company, has appointed Mr. C. H. Merz to report on the matter. Mr. Merz will leave for Buenos Ayres in August. It is said that a comprehensive scheme, including the electrification of the local and suburban lines of other companies as well, will be prepared.

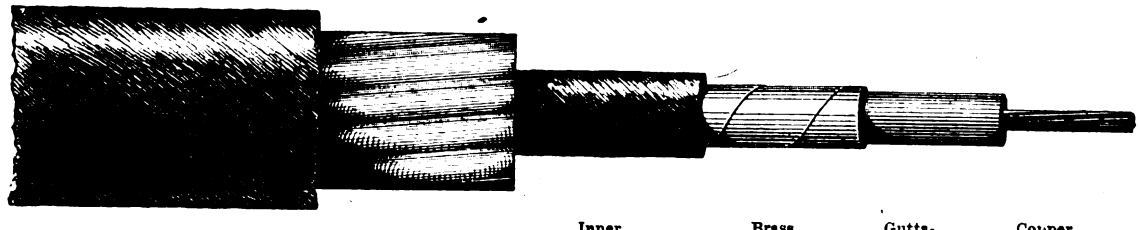
THE NEW VICTORIA AND TASMANIA TELEGRAPH CABLES

CONSIDERABLE interest has been evinced recently in Australia by the laying of two submarine cables from Flinders Bay, Victoria, to East Bay, Low Head, Tasmania, partly on account of the fact that these are the first cables that have been supplied to the order of the Commonwealth Government. The contract for the manufacture and the laying of the cables was entrusted to Messrs. Siemens Bros. and Co., Ltd., of Caxton House, Westminster, and the work was carried out under the supervision of Messrs. Clark, Forde and Taylor, of 4, Great Winchester Street, E.C., the consulting engineers appointed by the Postmaster-General of the Commonwealth. The cable was manufactured at the Woolwich works of Messrs. Siemens Bros. and Co., and completed towards the end of 1908.



The accompanying figures show the construction of the patterns of cable employed. The conductor of the cable is formed of a strand of $7 \times 0{\cdot}032''$ high conductivity copper wires, weighing 130lb. per nautical mile. The insulation consists of three layers of best gutta percha, also weighing 130lb. per nautical mile. The layers of gutta percha were applied without intervening coatings of Chatterton's compound, a method adopted by Messrs. Siemens Bros. and Co. in several of the Atlantic cables which they have manufactured. The G.P. core throughout the cable is covered with a spiral layer of brass tape as a protection against the boring habits of the teredo, a small mollusc which is found in all shallow waters of the ocean. The conductor resistance of the cable is 11·65 ohms and the inductive capacity 0·37 microfarad per nautical mile at 75° F. The insulation resistance of the completed cable is 2,300 megohms per nautical mile at 75° F. The main cable was formed by serving the brass-taped core with a layer of tanned jute yarn sufficient to form a bedding for ten galvanised "homo" iron wires, each 0·192in. diameter, and was further protected with two servings, in opposite directions, of Russian hemp yarn alternating with three coatings of compound. It has a breaking strain of 7·2 tons, and the weight is 75·1 cwt. per nautical mile in air, and 51·1 cwt. per nautical mile in sea water.

For the intermediate cable the core was served with a layer of tanned jute yarn of sufficient thickness to form a bedding for ten galvanised "homo" iron wires, each 0·276in. diameter, and was further protected with two servings of Russian hemp yarn, in opposite directions, alternating with three coatings of compound. This type has a breaking strain of 15 tons, and the weight is 145 cwt. per nautical mile in air, and 102·3 cwt. per nautical mile in sea water.

The shore-end cable was formed of the main cable with an additional serving of compounded yarn sufficient to take an armouring of fourteen galvanised iron wires, each 0·300in. diameter, and was further protected with two servings of Russian hemp yarn, in opposite directions, alternating with three coatings of compound. The breaking strain of this type is 30 tons, and the weight is 298 cwt. per nautical mile in air, and 215·4 cwt. per nautical mile in sea water.

Sections of Cables (Full Size).

Details of Main Cable (Full Size).

For the laying of the cables the contractors had chartered specially the s.s. *Chiswick*, which they fitted out for the expedition with the necessary cable tanks, machinery, and electrical testing apparatus. The vessel proceed to Australia *viâ* the Cape, and arrived off Flinders on January 31st. The shore-end of the East Cable was landed at Flinders on February 4th, and was laid out to a distance of fourteen miles, where it was cut and buoyed. The ship then returned to Flinders and landed the shore-end of the West Cable, which was thereupon laid across Bass Strait to within fifteen miles of the Tasmanian coast, where it was buoyed. The Tasmanian shore-ends of the two cables were landed next in East Bay, and the cables were then laid separately to the buoyed ends, where the final splices were made. The total lengths of the West and East cables are 186·568 and 186·945 nautical

Digitized by Google

miles respectively—*i.e.*, 373·513 total nautical miles of cable were laid. Soundings were taken at short intervals whilst the cables were being laid, and the greatest depth plumbed was forty-seven fathoms in sand and shell.

The interests of the Postmaster-General of the Commonwealth, during the laying of the cables, were in the hands of Mr. John Hesketh, Chief Electrician to the Department, who gave his certificate of complete satisfaction on the expiry of the thirty-one days' guarantee. In conclusion, we have to express our thanks to Captain R. Muirhead Collins, Representative of the Commonwealth in London, and to Messrs. Siemens Bros. and Co., Ltd., by whose courtesy we are enabled to publish the foregoing particulars of the cables.

THE APPEALS AGAINST THE REVOCATION OF THE FLAME ARC LAMP PATENTS

The Comptroller's Decision Reversed, and the Patents Upheld

ON Friday last the hearing of the appeal against the decision of the Comptroller-General of Patents to revoke the Bremer and Högner flame arc lamp patents, Nos. 18,786/02 and 23,606/02, in accordance with Section 27 of the new Patents Act, was resumed. A report of the first two days' hearing was given in ELECTRICAL ENGINEERING of March 18th, p. 255, and an abstract of the patents and the Comptroller's decisions with regard to them will be found in our issues of February 11th, p. 143, and February 25th, p. 178. The cases of the two patents were taken consecutively, but the judge's decision was given upon the two cases as a whole.

The revocation of both patents had been applied for by Mr. G. Braulik, on the ground that the patented articles were manufactured mainly outside the United Kingdom. The owners of the first patent, the British Westinghouse Co., put forward evidence to show that they had manufactured "to an adequate extent," but the Comptroller interpreted the meaning of that portion of the clause to be "to such an extent as will substantially satisfy the demand in this country, even if no importation take place." As most of the lamps sold under the patent had been manufactured by Messrs. Körting & Mathiesen abroad (and sold by the Union Electric Co. in this country), the Westinghouse Co. would, the Comptroller decided, have to give "satisfactory reasons" why they did not manufacture to a larger extent themselves. In response to this, the company pointed out that the Bremer patent was taken out in 1902, and that a short time afterwards a similar patent was applied for by Herr Högner, of Messrs. Körting & Mathiesen. The Union Electric Co., sold flame arc lamps to the number of 26 in 1903, 398 in 1904, and 2,348 in 1905. In the meantime, the British Westinghouse Co., having acquired the Bremer patent, had manufactured lamps in this country, but were not very successful. In 1905 the number sold was only 145. In March, 1906, the British Westinghouse Co. entered into an agreement with Messrs. Körting & Mathiesen, according to which the latter firm was granted a licence to manufacture under the Bremer patent for a period of five years; a royalty was to be paid on each lamp imported into the country, and the lamps were to be sold by the Union Electric Co. and the Westinghouse Co., or their agents, at the same price. Under these conditions the Union Electric Co. put on the market 3,467 lamps in 1906, and the Westinghouse Co. 106; in 1907 the figures were 3,612 and 537, and in 1908, 2,777 and 530 respectively, of which all were sold with the exception of 274 lamps of the Westinghouse Co. The Westinghouse Co. claim that they were in active competition with the Union Electric Co. all that time, but that the German-made lamps were preferred. As the agreement with Messrs. Körting & Mathiesen did not terminate until 1911, they asserted that that was a sufficient reason for their not manufacturing to a larger extent. It was also stated that there were several infringing lamps on the market. Writs had been served on the vendors of these lamps—namely, Messrs. D. Santoni, Messrs. Grevener, and Mr. G. Braulik, previous to the application by the last-mentioned party for the revocation of the patent.

In his decision, the Comptroller said that there was no evidence to prove that Messrs. Körting & Mathiesen could not, under their licence, manufacture lamps in this country and sell them at a profit. He concluded, therefore, that the reasons given for not manufacturing to a larger extent in this country were not satisfactory, and, subject to the present appeal, he revoked the patent.

In opening the proceedings on March 10th, Mr. A. J. WALTER, K.C., on behalf of the Westinghouse Co., stated that the British Westinghouse Co. had abandoned the argument relating to adequate manufacture, but held that the reasons given above for not manufacturing to a larger extent in this country were sufficient. The ATTORNEY-GENERAL (who appeared for the Treasury), and Mr. JUSTICE PARKER, discussed at some length the meaning to be put upon the expression "satisfactory reasons," and Mr. W. R. BOUSFIELD, K.C., on behalf of Mr. Braulik, held that the Westinghouse Co. had, by the agreement of 1906, knowingly placed it out of their power to create a successful lamp industry in this country. At the close of the hearing on March 11th, the proceedings were suspended for a few weeks, in order to enable the Westinghouse Co. to put in further evidence. In the ordinary course, additional evidence is not admissible in an appeal of this class, but special permission was given by the judge, in view of the particular circumstances of the case.

On Friday last, portions of the new evidence put in by the Westinghouse Co. in the form of affidavits from various members of their staff were submitted, and the witnesses were examined and cross-examined.

Mr. R. BELFIELD (Manager of the Westinghouse Patent Bureau), affirmed that the flame arc lamp was invented by Hugo Bremer, the patents extending from 1898 to 1901, and in 1901 these patents were purchased by Mr. George Westinghouse on behalf of the Westinghouse Co. It was part of the agreement that all future improvement inventions by Mr. Bremer should belong to the assignee. The patent in question, No. 18,786 of 1902, was acquired in this manner. After repeating the history of the growth of the business of Messrs. Körting & Mathiesen, and relating the difficulties met with by the Westinghouse Co. in producing a satisfactory lamp, Mr. Belfield pointed out that the only alternatives before the company were protracted and expensive litigation with the German firm, or an agreement. As Messrs. Körting & Mathiesen were willing to pay a substantial royalty under the Bremer patents, and to allow the Westinghouse Co. to compete with them on equal terms, the latter company came to the conclusion that this was the only business-like solution, particularly as the German firm agreed to give them a free licence under the Högner patent. Returning to the question of infringement, Mr. Belfield stated that an action was started in January, 1907, against D. Santoni & Co. (1906), Ltd., for an infringement of the patent in question, but on an amendment by the defendants of their particulars of objections, the Westinghouse Co. were advised to amend the specification; the action was accordingly discontinued and the specification amended. In December, 1907, however, a further action against D. Santoni & Co. was started. The Santoni Co. shortly afterwards went into liquidation, and by consent, judgment for a perpetual injunction was taken against them. Directly afterwards, actions against Messrs. J. & H. Grevener and Mr. George Braulik were started, and these are pending. In conclusion, Mr. Belfield stated that negotiations had been opened with Mr. Braulik, Mr. Bremer and others with regard to licences. Mr. Braulik, however, would not pay the required royalty; and the negotiations had not been concluded between the Westinghouse Co. and Mr. Bremer because the Westinghouse Co. insisted that, as a term of any licence, manufacture should take place in the United Kingdom.

Cross-examined by Mr. BOUSFIELD, Mr. Belfield stated that the A.C. "Excello" lamp sold by the Union Electric Co. did not embody the Bremer patent in question. He further stated that 584 Bremer lamps made under the previous Bremer patents had been purchased in 1901 and 1902, but these were not found satisfactory. Re-examined by Mr. WALTER, he said that in March, 1906, he had, on the authority of the Westinghouse Co., refused to give Mr. Braulik a licence under one patent, but would have granted a licence under all the patents.

Mr. P. EINERT (Chief Accountant of the Westinghouse Co.), stated that the company had paid for the purchase of the Bremer patents the sum of £15,000, and allowing for sales, and royalties received from the Union Electric Co., the net deficit to the end of the year 1908 had been over £23,000, in which the general expenses were not included.

On being questioned as to the existence of a company called

Digitized by Google

the Deutsche Bremerlicht Gesellschaft, he stated that it existed only on paper, and that it only owned patents. Since 1903, the costs of manufacture of flame arc lamps had been approximately double the return revenue from sales. Mr. George Westinghouse had acquired 50 shares in the Deutsche Bremerlicht Gesellschaft for the benefit of the British Westinghouse Co., but they had so far received no remuneration therefrom; the 50 shares were entered in the books to the total value of £1.

Mr. D. N. DUNLOP (Sales Manager of the Westinghouse Supply Department), stated that in the end of 1906 they bought 120 lamps from Messrs. Körting & Mathiesen, but when they found they were able to supply their own lamps, they returned 97 of these. Their own d.c. lamp was listed in their catalogue of 1906–7, in which the "Excello" lamps, both a.c. and d.c., were also listed, as they were not able to supply an a.c. lamp of their own, and were not sure that they could themselves meet the demand for the d.c. lamps. The catalogue for the following season contained only a.c. "Excello" lamps, which did not embody the present patent. In the September, 1908 catalogue the only lamps listed, both for a.c. and d.c., were of their own manufacture. He further pointed out that in many cases "Excello" lamps had been particularly specified, but that they had always tried their best to sell lamps of their own manufacture, and had spent in 1907–8 the sum of £500 in advertising them. They had been in active competition with the Union Electric Co. Further, at the present price, the profit per lamp was considerably larger than the royalty received by the company from the Union Electric Co., on the German-made lamps. They were now gradually overcoming the prejudice against their own lamps, and hoped to do good business in the coming season, in spite of the fact that there was a very large infringing competition. Their customers extended from public authorities and railway companies down to small retail shops. Competition was exceptionally keen; Mr. Braulik sold the cheapest. Infringing lamps were in use in London, Glasgow, Sheffield, and, in fact, in all the principal towns.

Mr. KARL VON KROGH (Superintendent of the Westinghouse Arc Lamp Department), said that all the patented parts of the Westinghouse arc lamps were made at Trafford Park. Only the globes, porcelain, and steatite insulators, and occasionally the outer covers, were not made there. When he commenced in this department in February, 1906, they had just stopped making lamps which had proved unsatisfactory, and a considerable number had had to be called in. The regular manufacture of a satisfactory lamp was commenced in December, 1906, but it was not until 1908 that the a.c. lamp was produced commercially. The number of lamps of this new type that had been made were between 1,300 and 1,400, of which 200 to 300 were now in stock. They could at present, as also in 1906, turn out about 25 lamps per day, but there was sufficient room to increase the output to at least 50 lamps per day. He also asserted that the profit at present on each lamp was considerably greater than the royalty received upon the German lamps. Their manufacture at present consisted in keeping up a regular stock of parts sufficient to make 500 lamps, and assemble them as required, or else in batches of 50 to 100 for stock. The jigs, patterns, dies, &c., which had been made for the purpose of manufacturing the last two patterns of lamps, had cost nearly £400. Work in the shops was at present very slack, but was not different to last year.

Mr. W. D. CRUMPTON (Purchasing Agent of the Westinghouse Co.) stated that after the purchase of the 584 lamps before 1902, none were purchased until the end of 1906, when 117 lamps, 61 a.c., and 56 d.c., were purchased for customers who had specified them. A further 224 lamps were purchased between December, 1906, and October, 1907, from Messrs. Körting & Mathiesen; 97 of these had been returned to the Union Electric Co., and 100 had been shipped direct to Buenos Ayres, so that only 27 were put to use or sold in this country.

Mr. G. BRAULIK, under cross-examination by Mr. Walter, admitted that he had not manufactured a solitary flame arc lamp, but stated that he intended to do so, and that was the reason why he wanted the patent revoked. He had had estimates prepared for the necessary plant which he intended to instal in his Lambeth Hill premises. Importation suited him very well, and he made a fair profit, but several large importers were selling still cheaper. The Government and several other bodies insisted on British-made lamps, and he wished to supply these. He admitted that the application for revocation was made after the writ had been served for infringement, and stated that although he then wished to obtain a licence to manufacture and sell the lamp, he had been forced to apply for the revocation. There was, he said, considerable competition, but the Westinghouse Co. was quite out of it. He complained that he could not obtain a licence under the Bremer patent without paying considerably more than Körting & Mathiesen.

Mr. BOUSFIELD then addressed Mr. Justice Parker, calling particular attention to the special circumstances of this case. The Westinghouse Co. had actually had the start of Messrs. Körting & Mathieson in this country in the sale of flame arc lamps. The Westinghouse Co. had allowed four years of unlicensed importation from the date of the patent, and this was followed by the agreement in March, 1906, which might be taken as legalising this importation. He held that this agreement absolutely prevented the Westinghouse Co. from establishing a business. By the agreement, he said, the Westinghouse Co. were able to purchase "Excello" lamps at 30 per cent. discount off the German published list prices, and it was obvious that they were able to sell these at a greater profit than that which they would make by manufacturing themselves.

Mr. J. HUNTER GRAY next addressed the Court on behalf of Mr. Braulik, and the Högner patent was next dealt with. This patent was taken out by Mr. Paul Högner, Chief Engineer of the German firm of Körting & Mathiesen, and, as explained above, an agreement was come to between this firm and the Westinghouse Co., to avoid expensive litigation as to the relative value of this and the Bremer patent. Mr. Braulik applied for the revocation of this patent on the same grounds as those on which the other application was made. The patentees argued that they claimed no protection, had taken no action against infringers, and had taken no royalties, and that, consequently, the lamp was not a "patented article" within the meaning of the Act. The Comptroller did not agree with this, however. In spite of Colonel Crompton's estimate, and Mr. Eck's evidence, that 60 per cent. of the lamps sold in the United Kingdom were manufactured here, the remaining 40 per cent. being imported, the Comptroller did not consider that this showed that the patented article was not manufactured mainly abroad, because it would leave altogether out of account the number of those lamps made abroad and not imported into this country. He therefore decided that the patented article was manufactured mainly outside the United Kingdom. The number of lamps manufactured by the Westinghouse Co. was given as between 500 and 600 a year, and this was not considered adequate by the Comptroller. Finally the Comptroller failed to see any good reason to prevent the patented article from being made in this country to an adequate extent by the patentee, since it has been manufactured in increasing quantities in this country by firms whom the patentee alleges to be infringers. He therefore decided to revoke the patent, subject to the present appeal to the Court.

After Mr. WALTER had opened the case for the appellants, Messrs. Körting & Mathiesen, evidence on affidavit was put in, and the witnesses were cross-examined.

Mr. H. E. MOUL (Technical Manager of the Union Electric Co.), stated that the manufacture of flame arc lamps by the Westinghouse Co. under the Högner patent was increasing, although at present small owing to the stated reasons. In June, 1908, he advised his company that the Högner and Bremer patents were practically identical, and that the sales of flame arc lamps was falling in consequence of infringements by importers and English makers. The sales would fall even more if the Bremer patent were declared invalid when the matter came under consideration in 1911, after the expiry of the agreement with the Westinghouse Co., and in consequence he had advised the directors not to consider the question of manufacture in this country. The cost of plant, &c., for manufacture would be at least £15,000. It would not be advisable to manufacture in this country until the Bremer and other patents had been proved valid. In his opinion, if the Bremer patent were proved invalid, the Högner patent would fall with it.

Cross-examined by Mr. BOUSFIELD, Mr. Moul admitted that whereas the German list price of Excello flame arc lamps varied at present between 85 and 120 marks (approximately from £4 5s. to £6), the list price in England was from £7 to £9. A discount on this latter figure, which varied according to the customer, between 10 and 30 per cent., was allowed. Mr. Moul could give no information with regard to the discount allowed in Germany. Trade had been very bad last year, but was improving. The Union Company supplied, he said, very much less than one-tenth of the total number of flame arc lamps sold in the United Kingdom. There were hardly any plain-carbon lamps sold now. Re-examined by Mr. WALTER, he stated that there were twelve English makers of flame arc lamps, all of which lamps contained the movement described in the Högner patent. The imported lamps were also infringements. In answer to Mr. Justice Parker, Mr. Moul said that Messrs. Körting & Mathiesen were the oldest established manufacturers of arc lamps, but that the three other foreign firms imported to about an equal degree. He further stated that, in his opinion, all flame arc lamps must contain one or other of the Bremer or Högner patents.

Mr. BOUSFIELD then addressed his lordship, repeating to a large degree the arguments given in connection with the revocation of the Bremer patent. He submitted that Messrs. Körting & Mathiesen had made no efforts to establish the manufacture of lamps under the Högner patent in this country, but Mr. Justice Parker pointed out that they had given the Westinghouse Co. a free licence, and had handicapped themselves with a royalty. Mr. Justice Parker thought that the existence of the previous Bremer patent somewhat excused the action of the company, but that if the Högner patent were held up against the Bremer patent, when the value of the latter is contested, it would be a good case for the revocation of the former. He said he would like to suspend the revocation of this patent until the expiration of the agreement, and would then feel inclined to revoke it if the Bremer patent were proved invalid, as the Westinghouse Co. in his opinion, were doing their best with regard to manufacture.

Mr. GRAY, speaking on behalf of Mr. Baulik, again emphasised

Digitized by Google

the point that there was no true competition, as there could be no underselling on the part of the British company. According to Mr. Braulik's statement, which had not been contradicted, the nett selling price in Germany was between £3 12s. and £4 2s., whereas the British nett selling price averaged about £5 12s. 6d. He could not agree with Mr. Moul's statements with regard to the inadvisability of establishing works in this country.

Mr. A. R. SARGEANT (representing the Attorney-General), said that from the point of view of the Crown there were not sufficient reasons for the revocation of the Bremer patent. He thought it was most natural that Messrs. Körting & Mathiesen should have come to an agreement with the Westinghouse Co., as they were the owners of the Bremer patents. If the Bremer patent were revoked, and not the Högner, a monopoly under the Högner patent would be created. The Westinghouse Co. had made considerable progress, and it would hardly be right to destroy the capital they had invested in this direction. He thought it was not a case where the British industry would be aided by revocation. With regard to the Högner patent, he thought it had been used to uphold the established German monopoly, and that equal rights had not been given to England.

When this point had been reached on Saturday, Mr. JUSTICE PARKER remarked that he would like to make terms; thus, for example, he would like to make an order to revoke the Högner patent unless a further licence were granted, after the litigation with regard to the validity of the Bremer patent had been disposed of, or unless successful manufacture were attained within a certain time, but by the Act he could only revoke or not revoke. It was suggested that this difficulty might have been overcome by adjourning the hearing, but this could not be done as the Comptroller's order for revocation was standing. The judge therefore decided that he would reverse the Comptroller's decision as to revocation, at any rate on the Bremer patent, and said that he would deliver his complete judgment, together with his ruling as to costs, on Tuesday.

On Tuesday, Mr. Justice Parker delivered judgment as follows:—

He stated that the patented article had been manufactured mainly outside the United Kingdom, and, therefore, the patentees had to prove that the patented article had been manufactured within the United Kingdom to a sufficient extent, or to give adequate reasons why it had not. They had also to show that they had not given preference to foreign over British industry, or otherwise done anything inconsistent with their obligations under the Act of 1907. With regard to the action for revocation of the Bremer patent, his lordship recapitulated the facts briefly, as follows:—In November, 1901, the British Westinghouse Co. acquired from Bremer a number of patents for improvements in arc lamps, together with the benefit of any further improvements made by him within the period limited by the contract. The consideration paid by the company under the terms of this contract, and modified by a later contract of November 28th, 1903, was £15,000. Prior to the acquisition of the Bremer patent, the company had not done any work in this country in connection with arc lamps, but subsequent to the agreement with Bremer, they set up works at Trafford Park, and then commenced to manufacture lamps under the patent with the object of developing the trade in this country. They purchased from Bremer a number of lamps which had been made abroad, but these proved defective, and in consequence the company acquired a bad reputation. They continued, however, at considerable expense, to make experiments to overcome the initial defects in the original lamps, and to remedy defects they had subsequently discovered in the lamps made by themselves. In these experiments they utilised the improvements in the Bremer patent of 1902, which they were entitled to do under the contract with Bremer.

Shortly after the acquisition of the Bremer patent, letters patent were granted to Högner, who was in the employment of Messrs. Körting & Mathiesen, for practically the same invention. This patent was No. 23,606 of 1902, and was the subject of the second of the appeals in this case. Messrs. Körting & Mathiesen acquired this patent from Högner in 1903, and commenced to import the lamps into this country. These lamps were admittedly infringements of Bremer's 1902 patent, if the latter were valid. This importation was carried on through the Union Electric Co., as agents. In 1903, 26 lamps were imported; in 1904, 398 lamps, and 1905, 2,348 lamps. It did not appear when the Westinghouse Company first became aware of the importation of these lamps. Until 1906 they were still experimenting, and in that year they thought they had obviated all the defects of the Bremer lamp. Apparently in that year they were aware of the importation of the lamps by Messrs. Körting & Mathiesen, and the question of the validity of the Bremer patent of 1902 then arose. In these circumstances the Westinghouse Company had two courses open for them: namely, either to commence proceedings against Messrs. Körting & Mathiesen for infringement, with the possible risk of having the 1902 Bremer patent declared invalid, and perhaps incidentally setting up Högner's patent, or to come to an agreement with Messrs. Körting & Mathiesen. The Westinghouse Company chose the latter course, and entered into the agreement of March 12th, 1906, by which they granted to Körting & Mathiesen a licence under the Bremer patents for 10 years from 1906, terminable at the end of five years by six months' notice to be given by either party, and subject to a certain royalty per lamp sold in the United Kingdom. On the other hand, the Westinghouse Co. were granted a free licence by Messrs. Körting & Mathiesen under the Högner patent for the same time. Under this agreement, Körting & Mathiesen had to pay Bremer also certain royalties on any lamps made in Germany under his patents, and imported into the United Kingdom. The contract further provided that licences should not be granted to any other firm at a less royalty than the one specified. In 1901 the Westinghouse Company made and sold under the Bremer 1902 patent between 100 and 200 lamps. In 1907 they made and sold 527, and up to November 2nd, 1908, they made and sold 530 such lamps, and had 274 still in stock. On the other hand, in 1906, Messrs. Körting & Mathiesen imported into this country 3,467 lamps; in 1907, 3,612; and in 1908, 2,777 lamps. It appeared, therefore, from this that the Westinghouse Company had not yet been very successful in competing with Messrs. Körting & Mathiesen in this country. They accounted for this by the fact that they had only recently manufactured arc lamps, and had acquired a bad name in these goods from the first. Further, they stated that Messrs. Körting & Mathiesen had not only the experience of years to help them but also a world-wide reputation, in consequence of which the public preferred their goods. Further, a number of cheap infringements were being made in, or imported to, this country, in connection with which the Westinghouse Company had instituted proceedings. The Company now believed that they were making a better lamp, and when these actions for infringement were settled they considered they would be able to compete successfully with Messrs. Körting & Mathiesen in this country, and also in the foreign market.

Against this it was argued by Mr. Braulik that, by entering into the contract with Messrs. Körting & Mathiesen, the Westinghouse Company had prevented themselves from putting competing lamps on the market, and had destroyed all chances of introducing an industry into this country, and therefore the Bremer patent should be revoked. It was also contended that the Westinghouse Company, by entering into the agreement, must have given up any *bonâ fide* intention of starting such an industry. After carefully considering the point, however, he had come to the conclusion that the Company had been, and still were, making a *bonâ fide* attempt to establish in this country an industry in arc lamps. They had acquired the Bremer patents, including the patent of 1902, for this purpose, and they had expended large sums of money with this end in view. It was by no means an easy thing to establish a business at the first time; both managers and workmen must buy their experience, and the situation was not made easier in view of the competition with Messrs. Körting & Mathiesen, who had such a high reputation, and at the same time possessed the entry to the market in this country. In fact, it was possible that Messrs. Körting & Mathiesen could have sold an inferior lamp to that manufactured by the Westinghouse Company, even at the same price, by reason of their reputation alone. Of course the Westinghouse Company might have succeeded, had they not entered into the agreement, in stopping the importation of the lamps by Messrs. Körting & Mathiesen by testing the validity of their patents; but he was not prepared to say that their decision to agree with Messrs. Körting & Mathiesen was a wrong decision. In fact, by this agreement they had handicapped Messrs. Körting & Mathiesen to the extent of the royalty which the latter had to pay on all lamps sold in this country, and in that way the Westinghouse Company seemed to have improved their own chances of establishing a business. They had limited their competitors' power to under-sell in the British market, and, if they succeeded in establishing their own patent rights and maintained a reputation for their goods before January 1st, 1911, they could determine the agreement of 1906, and altogether exclude the importation of lamps by Messrs. Körting & Mathiesen for the remainder of the term of the Bremer 1902 patent. He was satisfied that it was to the interests of the Westinghouse Company to manufacture under their patents to as large an extent as possible in the United Kingdom, for, leaving out of account the money expended in purchasing and experimenting with their patents, their profit on each lamp made and sold by them was greater than the royalty which they received on each lamp imported and sold by Messrs. Körting & Mathiesen. Therefore there was nothing in the Company's action which was inconsistent with a *bonâ fide* intention to manufacture and sell in this country. In his opinion, the Westinghouse Company had throughout used, and still were using, their best endeavours to fulfil the obligation arising out of the Act of 1907 to establish in this country an industry in the article which was the subject of the 1902 patent, and they had therefore proved to his satisfaction that their want of success up to the present time had been due to circumstances beyond their own control, and not to the manner in which they had exercised the rights conferred on them by the patent in question. The Act of 1907 was never meant to penalise want of success where the patentee had done his best, and he could not therefore come to the conclusion that the Company's patent ought to be revoked.

With regard to the Högner patent, Messrs. Körting & Mathie-

Digitized by Google

sen had not so strong a case for resisting its revocation as the Westinghouse Co. had for resisting the revocation of the Bremer patent. They had made no attempt to work the patent in this country otherwise than through the Westinghouse Co. On the other hand they could fairly claim that they had entered into a licence with the Westinghouse Co., who were presumably a competent firm to carry on the manufacture, and that this had precluded them from importing and selling competing lamps without paying a substantial royalty. A decision with regard to this patent presented some difficulty. For some years, litigation had been pending as to the validity of the Bremer patent of 1902, and until this was decided, Messrs. Körting & Mathiesen had, he thought, some excuse for hesitating to lay down plant to work the Högner patent in this country, and more especially as their licence under the Bremer patent of 1902 was terminable on January 1st, 1911. If the Bremer 1902 patent was declared invalid, and the Högner patent valid, and Messrs. Körting & Mathiesen did not forthwith take steps to work the Högner patent, or to ensure that it be worked to an adequate extent in this country, then he thought they would have great difficulty in resisting its revocation. He had, however, come to the conclusion, that, in the present circumstances, he might fairly accept as satisfactory the reasons given for the small extent to which the patent had been worked in this country, the more so, because the revocation of this patent might make things even more difficult for the Westinghouse Co., who, as he believed, were doing their best to create an industry.

He proposed, therefore, to reverse the Comptroller's decision revoking both these patents. He would allow no costs except the costs of the Attorney-General, which, he directed, should be borne by Mr. Braulik and the Westinghouse Co. in equal shares in the one case, and by Mr. Braulik and Messrs. Körting & Mathiesen equally in the other case. He would not, however, disturb the directions of the Comptroller-General as to the costs of the proceedings before him.

At the conclusion of the reading of his judgment, Mr. Justice Parker once more repeated his statement that his decision to allow further evidence in these two cases must not be taken as a precedent governing other cases.

INSTITUTION OF MINING ELECTRICAL ENGINEERS

Formation of South Wales Local Section

A MEETING of the above Institution was held at the University College, Cardiff, last Saturday, Mr. Sydney Walker in the chair. Mr. Walker opened the meeting with a few remarks on the objects of the Institution, emphasising the point that all practical electrical engineers engaged in collieries should make a point of joining it in order to give the benefit of their knowledge to other members by reading Papers before the different local sections. The following officers were then elected for the South Wales section:—President, Mr. Sydney F. Walker; vice-president, Mr. E. M. Hann (General Manager of the Powell Duffryn Co.); Mr. Llewellyn (Baldwins, Ltd.); Mr. G. F. Flanders (Engineer to the Powell Duffryn Co.); secretary, Mr. E. Ivor Davies, B.Sc., Rock Cliffe, near Llandebie, R.S.O., Carmarthen. The election of members of council was deferred until the next meeting. Meetings are to be held as far as possible alternately at Cardiff and Swansea.

PARLIAMENTARY INTELLIGENCE

GREENOCK CORPORATION BILL.—This General Powers Bill was under consideration of the Local Legislation Committee, late the Police and Sanitary Committee, of the House of Commons last week. One of the provisions is for the erection of a refuse destructor in connection with the electric lighting undertaking, at a cost of £20,000, for which the consent of the Scottish Office has already been obtained. In granting the clause the chairman stated that the committee did not view with pleasure the obtaining of loans before statutory authority had been granted.

PROGRESS OF ELECTRICAL BILLS.—The Preston, Chorley, and Horwich Tramways Bill and the York Town and Blackwater Gas (Electric Lighting) Bill were read a second time in the House of Lords on Wednesday last week. The Tramways Provisional Order Confirmation Bill No. 1, and Electric Light Provisional Order Confirmation Bills Nos. 1 and 2 were read a second time in the House of Lords on Wednesday last week.

The West Kent Electric Power Bill was read a third time and passed in the House of Lords on Monday. In the House of Commons on Monday, the South-Western and Isle of Wight Junction Railway Bill was read a second time.

The Southport and Lytham Tramroad (Abandonment) Bill was read a third time and passed in the House of Lords on Tuesday.

HOLYWOOD TRAMWAYS.—This Bill was passed by the Unopposed Committee of the House of Commons on Thursday. It grants an extension of time for three years for the construction of the lines.

LONDON COUNTY COUNCIL TRAMWAYS BILL.—Sir George Doughty's Committee of the House of Commons continued consideration of this Bill on Thursday. The only other opposed portion, in addition to that dealt with in our last issue, was the construction of a tramway continuing the existing double line in Battersea Park Road along Battersea Bridge Road and over Battersea Bridge to King's Road, Chelsea, at an estimated cost of £71,020. The opposition was on the part of property owners, and related to compensation, but the committee decided that sufficient protection was given in the Bill.

EDGWARE AND HAMPSTEAD RAILWAY BILL.—All opposition to this Bill having been withdrawn, it has been referred to the Unopposed Committee of the House of Commons. It proposes to deviate the line at Hendon and to revive certain powers for the purchase of land.

CENTRAL LONDON RAILWAY BILL.—In our last issue we briefly referred to the consideration of this Bill by a committee of the House of Commons, presided over by Sir J. Compton Rickett. The object of the measure is to extend the present line from the terminus at the Bank to Liverpool Street at a cost of £300,000, and in order to secure a return of 5 per cent. upon this outlay it is estimated that an additional 4,000,000 passengers will have to be carried annually. The Bill was supported by the Great Eastern Railway Co., who are giving the land for the construction of the new tube station at Liverpool Street, and the London & North-Western Railway Co. The only opposition on preamble was by the Metropolitan Railway Co., who opposed on the question of competition. The committee, however, passed a preamble of the Bill, with a modification in one of the clauses in order to allow interchange of passengers, by means of subways, between the Central London Railway and the North-East London Railway. A minor object of the Bill was to connect the British Museum station of the Central London Co. with the Holborn station of the Great Northern, Piccadilly & Brompton Railway by means of a subway in which there is a moving platform.

TRAMWAY ASSESSMENT.—In answer to a question in the House of Commons on Thursday with regard to the assessment of the Metropolitan electric tramways in Paddington, Mr. John Burns stated that the 1 mile 6¾ chains of line belonging to the company in this district is assessed at £1,000 gross value, and £500 rateable value. The assessment was fixed at the last quinquennial valuation, when the tramway was worked by horses. The assessment of the line will be dealt with at the next valuation in 1910.

YORKTOWN AND BLACKWATER ELECTRIC LIGHTING BILL.—This Bill was ordered to be reported for third reading by the Unopposed Committee of the House of Commons on Tuesday. It grants the Yorktown & Blackwater Gas Co. powers to supply electrical energy.

ELECTRIC LIGHTING PROVISIONAL ORDER CONFIRMATION BILL (No. 2).—This Bill, which was ordered to be reported for third reading by the Unopposed Committee of the House of Commons on Tuesday, confirms electric lighting provisional orders granted by the Board of Trade for Dunfermline and District.

PRESTON, CHORLEY, AND HORWICH TRAMWAYS BILL.—This Bill was ordered to be reported for third reading by the Unopposed Committee of the House of Commons on Thursday. It authorises an extension of time for the construction of tramways authorised in 1903.

DUDLEY CORPORATION BILL.—This Bill, which was passed by the Unopposed Committee of the House of Commons on Thursday, confirms an agreement with the British Electric Traction Co. for a lease of the tramways and light railways in Dudley for 30 years.

FOLKESTONE, SANDGATE, AND HYTHE TRAMWAYS.—Something of a surprise awaited the promoters of this Bill in the House of Commons on Tuesday, when the chairman announced that the Committee found the preamble of the Bill proved only so far as the extension of time for the completion of works, &c., was concerned. This means that the National Electric Construction Co is still bound by its agreement with the three local authorities concerned, by which they undertook to instal the Dolter surface contact system, or some other surface contact system agreed upon by the parties. As matters stand at present, the company is absolutely debarred from installing the overhead system. The company has now a further two years in which to put its Act into force.

Newcastle Section of the Institution of Electrical Engineers.—On page 462 of our last issue Mr. A. Drummond, the retiring chairman, was described as being connected with the North Eastern Railway. This is incorrect, as Mr. Drummond is engaged with the National Telephone Co., and has been for the last 27 years.

Fire on the District Railway.—A fire occurred upon the District Railway at Charing Cross late on Monday night, the trains being brought to a standstill owing to the necessity for cutting off the current. None of the passengers were injured, but traffic was suspended between Charing Cross and Temple for an hour or two.

ELECTROBUS CO. AND ITS BATTERIES

AN action was commenced last week in the King's Bench Division of the High Court by Mr. C. A. Gould, of the Gould Storage Battery Co., of America, against Dr. E. H. Lehwess, of London, in respect of a contract for the supply of batteries for the London Electrobus Co. The claim was for £3,200, the price of certain batteries and accessories supplied. It appears that in connection with the formation of the London Electrobus Co., Dr. Lehwess went to America to see Mr. Gould for the purpose of securing the English rights of the Gould battery. Eventually it was agreed that an English Gould Storage Battery Co. should be formed with a cash capital of at least £25,000. and as the purchase price of the English patent rights Mr. Gould was to have 55 per cent. of the shares allotted to him. Dr. Lehwess registered this company in November, 1906, and cables passed between the parties, from which plaintiff understood that the actual cash had been subscribed, with the exception of £4,000. Relying upon this, 15 Gould batteries of 42 cells each were sent over, the purchase price being £172 each, subject to certain tests provided for in the contract, and which were to be attended by experts both of the Electrobus Co. and of the Gould Co. The plaintiff's case was that instead of the shares in the English Gould Storage Battery Co. having been issued for cash, they had been issued to the Asiatic Banking Corporation "for its valuable services"; and that, further, the defendant would not permit the tests of the batteries, provided for in the contract, to be carried out. In reply to this, the defence alleges that the batteries have never worked satisfactorily, and that when they complied with the tests the company would pay for them. It was alleged that although the Gould batteries were satisfactory at first, they very soon began to be unsatisfactory, and a number of them gave out during the journeys; and Mr. W. M. Mordey gave evidence to the effect that no battery at present manufactured could have fulfilled the conditions of the contract. The unsatisfactory working of the batteries was advanced by the defendant as the reason why the test was not allowed to take place, employees of the company, including the general manager and electrical engineer, being called for this purpose. The plaintiff, however, put in the journey sheets, which showed that on many occasions a number of the batteries completed three journeys on the Victoria to Liverpool Street route, whereas the contract only called for two journeys.

During the evidence and cross-examination of Dr. Lehwess, the Judge, Mr. Justice Phillimore, informed counsel for the defendant that the evidence with regard to the tests, and the manner in which the Gould Co. had not been allowed to make them, had left a very bad impression on his mind. At another point in the proceedings, his Lordship stated that the evidence of the plaintiffs with regard to the flotation of the Gould Storage Battery Co. here constituted a charge of false and fraudulent misrepresentation against the defendant to which he wished to have a specific answer. Dr. Lehwess stated that he was distinctly of the opinion that the plaintiff was aware, from the various discussions they had, that no cash had been actually subscribed. His Lordship, however, was by no means satisfied with the wording of the cable, which read, "All shares issued cash about £4,000 reserved." The meaning of this cablegram varied with the position of the stop—whether it was placed before or after "cash." Counsel for the defendant claimed that Mr. Gould could not have read it as "All shares issued cash," as he had himself received a large number of shares without paying for them. Later, also, a letter was sent to Mr. Gould stating that there was only £4,000 cash available. It appears that the batteries were subjected to satisfactory tests, but that the independent engineer appointed, Mr. Vaughn, was not present at these tests, so that Dr. Lehwess was not bound to pay for the batteries by the agreement. A second agreement was made between Mr. Gould and Dr. Lehwess, according to which certain benefits were conferred on the former.

Mr. Justice Phillimore, in giving judgment on Tuesday, stated that, in his opinion, Mr. Gould had acted under the impression that there were several thousands of pounds in the company, and that Dr. Lehwess knew that this was his belief. Mr. Gould had made his case difficult, however, by the excessive nature of his requirements. Dr. Lehwess, knowing that there was only £107 to the credit of the company, had, he thought, misled Mr. Gould by sending an ambiguous telegram. His lordship thought that the second agreement was an admission of misrepresentation on the part of Dr. Lehwess, and that it was in itself of the nature of a satisfaction. He could therefore give no damages for misrepresentation, but only for breach of contract. He was of the opinion that Dr. Lehwess had used his powers of control over the Electrobus Co.'s officials to prevent the presence of Mr. Vaughn at the tests, as with these powers it would have been a most simple matter to have arranged for proper official tests. The excuses given by the defendants were, he thought, ridiculous. He would therefore give the plaintiff damages for non-acceptance of goods. Although he would like to give plaintiff damages with respect to the whole of the goods supplied, he was only able to give him the sum of £2,828 15s. in respect of the 15 complete batteries, less their value when returned at the expiration of the three years as arranged. This value he put at £20 per battery, as he could only consider them as so much scrap lead, there being no attempt made to keep them in condition. He therefore allowed the plaintiff, Mr. Gould, £2,528 15s. damages, and costs.

LOCAL NOTES

ABERDEEN: *Electrical Cooking Apparatus, &c.*—The Electrical Engineer has been authorised to provide a small stock of electrical heating and cooking apparatus for hiring out. In a discussion on this proposal, considerable objection was taken to the Corporation interfering with private traders in this respect, it being stated that within the last three months one firm in Aberdeen had sold over £100 worth of electric heating and cooking apparatus. The reply of the Chairman of the Electricity Committee was to the effect that the Corporation already hired out gas fittings, and he did not see why any distinction should be made between two departments in this respect.

Supply to Tramway Company.—The Aberdeen Suburban Tramways Co. and the Corporation have agreed upon Mr. W. H. Patchell to act as arbitrator on the question of the price to be paid by the company for electrical energy and other distinction should be made between the two departments in this parties.

ACCRINGTON: *Electricity Accounts.*—The accounts of the Municipal Electricity Undertaking for the year to March 31st shows a net profit of £2,542, compared with £604 for the preceding year. The sum of £500 has been ear-marked for hire purchase wiring installations, £293 for the purchase of meters and motors, and £884 for the replacement of superseded plant. The balance of £865 is carried forward.

ACTON: *Lease of Electricity Undertaking.*—The Council at their last meeting decided to hand over their electricity undertaking to the Metropolitan Electric Supply Co. on a lease of 37 or more years, subject to the company accepting the Council's schedule of charges.

ALDERSHOT: *Light Railway Order.*—The Board of Trade have recently confirmed the Aldershot and Farnborough Light Railway Order of 1909, authorising the construction of light railways in the urban districts of Aldershot and Farnborough in the county of Southampton, and in the rural district of Farnham, in the county of Surrey.

BARNSLEY: *Electricity Profits.*—The accounts of the Electricity Department for the year to March 31st show a profit of £1,429. The sum of £1,000 has been transferred to the relief of rates, and the balance added to the reserve fund.

BELFAST: *Cost of Tramway Energy.*—With reference to the complaint of the Tramway Manager, mentioned in our last issue, to the effect that the Tramways Department was being considerably overcharged in respect of the supply of electrical energy, the Sub-Committee have now reported, recommending that the following items in the revenue expenses of the electrical undertaking be excepted in ascertaining the total cost of production of electrical energy for the tramways:—Wages of linesmen, &c.; repairs and renewals of mains; repairs on consumer's premises; maintenance of motors for hire; maintenance of meters; repairs and renewals of public lamps; rates and taxes, mains and services; meter inspection. It is also recommended that the energy for the tramways shall be measured at the power station. The City Accountant has been instructed to revise the price of current charged to the tramways undertaking for the year to March 31st, upon this basis.

BOURNEMOUTH: *Electric Supply Charges.*—In consequence of the higher efficiency of metal filament lamps, and its effect upon the revenue of the company, the Bournemouth & Poole Electricity Supply Co. are making a slight increase in their charges.

BURTON-ON-TRENT: *Electricity Accounts.*—In our note upon the electricity accounts of the Corporation for the year to March 31st, in our issue for May 13th, we mentioned that the works costs were 1·823d. We regret, however, that this is an error, this figure representing the total cost per unit, including capital charges. The works costs were 0·810d. per unit, and the total costs 1·033d. per unit.

CARLISLE: *Supply Outside Boundaries.*—The Corporation has decided to apply for a provisional order authorising the supply of electricity outside the boundaries of the borough.

CREWE: *Electricity Profits.*—The electricity undertaking for the past year made a profit of nearly £1,000, of which £500 has been transferred to relief of rates.

EALING: *Electric Wiring.*—In view of the large amount of property now being erected in the Borough, the Electrical Engi-

Digitized by Google

neer has been instructed to obtain information as to the possibility of wiring the premises free of charge.

EDINBURGH: *Colinton Tramways.*—The Midlothian County Council has decided to oppose the proposed scheme for the construction of electric tramways in the Colinton district.

FALKIRK: *Electrical Undertaking.*—A special committee has been appointed to consider and report upon the question of electricity supply in the Borough.

HANLEY: *Electricity Supply in Milton.*—In reference to the recent instructions from the Corporation to the Engineer, to prepare a scheme for supplying the Milton district with electricity, the North Western Electricity & Gas Power Corporation have pointed out to the Council that they have certain powers of supplying this district, and that steps are being taken for putting them into force.

HEYSHAM: *Provisional Order Revoked.*—The Board of Trade has revoked the Electric Lighting Provisional Order granted to the Council in 1904.

HEYWOOD: *Tramway Receipts.*—The working of the tramways for the past year shows a loss of £1,202.

HULL: *Telephone Accounts.*—The report of the Municipal Telephone Committee for the year to March 31st shows gross receipts of £10,592 against £9,567 for the previous year, and gross profits of £4,443 against £3,971. After meeting capital charges and Post Office royalties, and placing £2,311 to reserve, there is a surplus of £1,040. The Post Office royalties for the year amounted to £1,082, and the total paid to date on this account is £3,778. The capital expenditure of the year amounted to £3,111, this account now standing at £57,858.

INDIA: *Electricity Supply.*—The Municipal Council of Simla propose to apply for a license under the Indian Electricity Act, in order to enable them to take over the water-power installation at Basantpur, in the Nauti Khud, when it is completed in about two years' time.

LEEDS: *Tramway Extensions.*—The tramway extension of the Corporation from Horsforth to Guiseley, a distance of about 2½ miles, was inspected on behalf of the Board of Trade last week. The track is double throughout, and it is hoped to receive the official sanction in time to put the line into operation for the Whitsun holidays.

Tramway Intercommunication.—Owing to the success of the extensible gauge tramcar track which has been in use between Leeds and Bradford for some time, the Leeds Corporation propose to largely extend the service of cars between the two towns. The gauge of the two systems is different, being 4 ft. at Bradford and 4 ft. 8½ in. at Leeds, and the invention of the extensible truck, which was described in ELECTRICAL ENGINEERING for April 25th, 1907, Vol. I., p. 723, was the result of the desire for through running between the two towns.

LONDON: *London County Council: Tramway Estimates.*—The Highways Committee have submitted the annual estimates of the tramways undertaking for the year 1909–10. These provide for an expenditure of £1,800,000, including £200,000 in respect of the purchase and construction of tramways for which powers are being sought in the present session of Parliament. The revenue estimates for the year are upon the basis of receipts of 1s. per car mile and working expenses of 6·85d. per car mile, leaving a gross profit of 5·15d. The estimated car mileage is 39,363,000, against 31,962,784 car miles in the year just ended. The committee, in presenting these estimates, point out that the question of the proper allocation of the cost of street improvements connected with the tramways has not yet been settled, and is still before a Joint Committee of the Finance, Highways and Improvements Committees.

London County Council: Tramways.—The Highways Committee recommend that two sets of sand-crushing rollers, screens, elevators, &c., should be installed at the Greenwich Road depôt for the purpose of supplying the necessary sand for the Council's tramways. By doing this work itself the Highways Committee anticipates a saving of £1,500 per annum compared with the cost of purchasing from merchants as is the case at present.

Last year an agreement was entered into for the purchase and reconstruction on the overhead trolley system of the horse tramways in Lea Bridge Road, and for their working by the Leyton Urban District Council until August 5th, 1911. The Highways Committee of the London County Council now recommend that an agreement upon similar terms should be entered into with the Leyton Council for the working of the remainder of the lines in the Lea Bridge Road, joining up with the Lower Clapton Road.

Islington: Proposed Bulk Supply.—The Great Northern & City Railway Co. have suggested to the Council that as their railway power station is only half loaded at present, it might be possible for an arrangement to be come to for the company to supply the Council with electrical energy in bulk. The matter has been referred to the special committee, which is now considering the general position of the Council's electrical undertaking.

Kensington & Knightsbridge Electric Lighting Co.—This company recently appealed against the assessment of their property in Kensington, which at present stands at a rateable value of £13,500. It was claimed that this should be reduced to £8,628, but Mr. Leslie Vigers, to whom the appeal was referred, decided in favour of the Borough Council. The assessment of £13,500 therefore remains unaltered.

Marylebone: Street Lighting.—The Electricity Supply Committee report that the conversion of street lamps to electric lighting has been carried out in Harley Street, and the results are very satisfactory. From the figures of this work, they find that the cost of the whole conversion of 1,964 street lamps will be under £7,000, as against the previous estimate of £8,000. After carefully considering the matter, they recommend the Council not to appeal to the Local Government Board against the refusal of the London County Council to sanction the loan. The best course will be to pay for the work out of the balance of profit in hand, and to set aside out of the profits of the undertaking during the next three years a sum equal to the amount expended on the execution of the work. The recommendation was carried at the last meeting of the Council.

MARKET HARBOROUGH: *Electric Lighting.*—The Council are issuing circulars with a view to ascertaining the probable demand for electricty, in order to determine whether to put into force the electric lighting Provisional Order which it holds.

MIDDLESBROUGH: *Electric Cranes.*—The North Eastern Railway Co. are erecting two additional electric cranes at their docks here.

NORWICH: *Electricity Accounts.*—The accounts of the electricity undertaking for the year to March 31st show a gross profit of £18,142. After meeting capital charges there is a balance of £3,800, from which has to be deducted £850 for depreciation. The balance of £1,200 is to be applied to relief of rates.

SAO PAULO: *Electric Lighting Concession.*—The directors of the Sao Paulo Tramway, Light & Power Co. have now received definite advice from Brazil with reference to the statements which have been circulated on the subject of the threatened organisation of a rival company and local opposition to the company. They officially announce that these statements are misleading, and for the most part without foundation. The facts are that an application was made to the Mayor of Sao Paulo for the grant of a concession to a rival company. On the granting of the concession being opposed by the company, the Corporation referred the matter to its legal advisers, who advised that the application could not be legally granted, as it would constitute an infringement of the already existing rights of the company, and the application was thereupon refused by the Municipal Council, thus officially confirming the position held by the company.

SOUTH AFRICA: *Electric Mono-Rail.*—It is reported that the Pretoria Power Co. has been formed to undertake, among other work, the construction of an electric mono-rail from Johannesburg to Pretoria.

SOUTHEND: *Tramway Running Powers.*—An agreement has been come to for mutual running powers over the tramways of the Corporation and those of the Southend & Colchester Light Railway Co.

Electric Lighting Accounts.—The accounts of the electricity undertaking for the year to March 31st show a net profit of £1,200, and after adding the balance brought forward, there is a sum of £2,027 available.

Light Railways.—The Corporation are making an application to the Light Railway Commissioners to revive the powers granted by the Southend-on-Sea and District Light Railways Order, 1904, to extend the time for their construction, and to abandon a short length of line included in the Order.

TRINIDAD: *Telephones.*—The Trinidad Government has granted a concession for 30 years to a Canadian company formed to take over the telephone system from the Island.

WAKEFIELD: *Tramway Speeds.*—The Wakefield & District Light Railways Co. have applied to the Board of Trade for permission to increase the speed from 10 miles to 12 miles per hour on one section of their lines; from 8 to 10 miles per hour on another section, and to 8 miles per hour on all curves with a radius of less than 150 ft.

WATFORD: *Bonuses for Stokers.*—A system of coal bonuses has been approved by the Council. The scheme is to be at first tried for twelve months. It is estimated that its adoption will mean a saving of £400, and of this approximately the benefit which the men will receive will be about 10 per cent.

WESTON-SUPER-MARE: *Tramways.*—The Weston-super-Mare and District Electric Supply Co. propose to apply to the Board of Trade for an extension of time for the completion of the tramways authorised by the Tramway Orders of 1900 and 1901.

Wireless Telegraphy.—Rules have been issued to the effect that no apparatus for wireless telegraphy on board merchant ships, whether British or foreign, shall be used whilst in any of the harbours of Gibraltar, except with the written permission of the Governor. The making or answering of signals of distress are excepted. The Bill requiring all steamers to be equipped with wireless apparatus, which was introduced in the Canadian Parliament, has been shelved for the present, for the reason, it is said, of seeing what steps the British Government is taking in this direction.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

ABERDARE.—The adjourned Local Government Board inquiry into an application of the Council for sanction to borrow £17,000 for the purpose of electric lighting was resumed and concluded last week. There was a considerable amount of opposition, including that of the South Wales Electrical Power Distribution Co., and the Powell Duffryn Colliery Co., for whom evidence was given by Mr. W. A. Chausen and Mr. C. P. Sparks respectively. The general trend of the opposition is that the area is much too small for carrying on a profitable electrical undertaking.

ASHTON-UNDER-LYNE.—An application is to be made to the Local Government Board for sanction to borrow £48,424 for extensions to the electricity works.

BRAY.—A Local Government Board inquiry was held on May 20th into an application of the Council to borrow £2,600 for electric lighting purposes. The application was opposed by Mr. T. P. Bradshaw, a member of the Council, and ex-chairman of the Electric Light Committee, on the following grounds :—(*a*) A portion of the money had been already spent and allowed for and included in the rate recently struck; (*b*) the works made a small loss in previous years, and that therefore the Council were bound to charge the maximum statutory price (8d. per unit) before they could take money from the rates to pay such deficits; (*c*) that the Council were not charging the full import and export fees at the harbour as allowed by statute. The Inspector took note of Mr. Bradshaw's objection, and the inquiry proceeded.

DUDLEY.—The Council invite tenders for the supply, delivery, and erection of a motor generator and switchgear. Particulars from the Clerk, and tenders by June 10th.

GILLINGHAM.—Tenders are invited for 120-kw. and 140-kw. Diesel oil engine generating sets. A loan of £3,000 is to be applied for.

HULL.—The Guardians of Sculcoates Union invite tenders for a 15-kw. direct-current steam generating set. Particulars from Messrs. Maxted, Knott & Coles, Burnett Avenue, Hull, and tenders to the clerk by June 9th.

INDIA.—Mr. J. W. Meares, Electrical Adviser to the Indian Government, has prepared a scheme for the electric lighting of Shillong, at an estimated cost of £122,000.

LEIGH (Lancs).—The Leigh and Atherton Joint Sewerage Board invite tenders for high-speed vertical steam engines, dynamos, motors, cables, &c. Full particulars from the Engineers, Messrs. Banks, Fairclough & Stephen, Leigh, Lancs, and tenders by June 11th.

LONDON: *London County Council.*—Tenders are invited for (*a*) the supply and fixing of steam exhaust feed and drain piping valves, &c.; (*b*) the supply and fixing of cast-iron condensor water-pipe valves, &c., at the Greenwich power station. Particulars from the Clerk, and tenders by June 22nd.

Bermondsey.—The Finance Committee of the London County Council have approved of a loan for electric lighting purposes of £5,262.

Southwark.—Application is to be made to the L.C.C. for sanction to borrow £2,130 to meet the estimated capital expenditure of the undertaking during the year 1909-10. The total is made up as follows :—Meters and indicators, £450; services (house connections), £600; mains, £1,000; instruments, £80.

SOUTHAMPTON.—Tenders are invited for low-tension trunk mains. (See an advertisement on another page.)

SWANSEA.—The Engineer has been instructed to submit alternative schemes for the provision of coal storage, and to make arrangements for storing patent fuel.

TUNBRIDGE WELLS.—The Corporation invite tenders for the supply and delivery of high and low tension cables during the ensuing twelve months. Particulars from the Consulting Engineer, Mr. H. Boot, at the Electricity Works, and tenders by June 12th.

WARRINGTON.—The Electricity and Tramways Committee invite tenders for cables and 12 months' supply of motors and transformers. Particulars from the Borough Electrical and Tramways Engineer.

WORKSOP.—Cable extensions have been authorised.

Miscellaneous

BEDFORD.—Subject to the consent of the Local Government Board, 58 street gas lamps are to be substituted by 64 electric lamps at a cost of £630. The new lamps will have an illuminating power of 3,840 c.p. against 928 c.p. at present.

CLYDE NAVIGATION TRUSTEES.—The Trustees of the Clyde Navigation invite tenders for the supply of stores during the year commencing July 1st, including electrical stores.

DEVONPORT.—Electrical capstans are to be installed at the Admiralty dockyard.

LONDON: *London County Council.*—The Highways Committee recommend an expenditure of £7,000 upon the anchoring of tramway track rails during the coming financial year.

Stepney.—The Council require (1) ampere-hour meters, demand indicators, and time switches; (2) arc lamp carbons. (See an advertisement on another page.)

ROUMANIA.—A German Consular report states there is an increasing demand for all kinds of electrical machinery in Roumania, on account of the opening up of new oil fields and new timber-producing sites.

A company is to be formed in Bucharest for the construction of tramways, with a capital of £120,000.

SOUTHEND.—Three sets of electric route signals, at an estimated cost of £48, are to be purchased for the tramways undertaking.

SOUTH WALES.—The Penrikyber Navigation Colliery Co. invite tenders for electrical stores during the year commencing July 1st. Particulars from the Secretary and tenders by June 5th.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

N.—Improvements at York Road School, Islington (£9,839). Builders, C. P. Roberts & Co., 138 St. Paul's Road, Highbury.

S.E.—Proposed school for the physically defective, Venetian Road, Norwood (120 places). T. J. Bailey, architect, L.C.C. Education Committee, Victoria Embankment, E.C.

Proposed school for the physically defective, Plassy Road, Lewisham (80 places). T. J. Bailey, architect, L.C.C. Education Committee, Victoria Embankment, E.C.

W.C.—Block of offices, Salisbury Square. Architect, F. W. Foster, 41 Bedford Road, W.C.

Building new offices, Queen Square, W.C. Builders, Chinchen & Co., Harrow Road, N.W.

Italian Hospital, Bloomsbury. Architects, Browett & Taylor, 9 Warwick Court, London.

Mission Hall, Kingsway. Architects, Gordon & Gunton, Salisbury House, Blomfield Street, E.C.

PROVINCES.

ALLOA.—Banking premises. Architect, J. M. Dick Peddie, 8 Albyn Place, Edinburgh.

ASHBY.—School. Architect, J. Day, 8 New Street, Leicester.

BOOTLE.—Telephone exchange. Architect, Bromley & Watkins, Prudential Buildings, Nottingham.

CAMBRIDGE.—House (£1,933). Architect, A. P. MacAllister, 20 St. Andrew's Street, Cambridge.

CHESTER.—Skating rink. Architect, W. T. Lockwood, 88 Foregate Street, Chester.

CREWE.—Police station. Architect, H. Beswick, Newgate Street.

DARLINGTON.—Skating rink. Architects, Kitching & Lee, 14 Blackwellgate, Darlington.

DEVONPORT.—Sunday school at St. Mark's Church, Ford (£970). Architects, Hine, Odgers & May, 23 Lockyer Street, Plymouth.

DUBLIN.—A Local Government Board inquiry was held on Friday into an application by the North Dublin Union for sanction to borrow £2,000 for electric lighting at the Workhouse and North City Dispensaries.

FALKIRK.—Skating rink. Architect, A. Gauld, High Street West, Falkirk.

GLASGOW.—Addition to church (£7,000). Architect, J McKellar, 45 West Nile Street, Glasgow.

LEEK.—Tenders are invited for wiring Mount Pleasant Chapel. Particulars from Mr. H. Ellerton, Derby Street, Leek.

LIVERPOOL.—Telephone exchange. Architect, T. M. Deane, 15 Ely Place, Dublin. Builders, Isaac Dilworth, Liverpool

LONDONDERRY.—Police court. Architect, P. H. Elliot, 12 Castle Street, Londonderry.

MANCHESTER.—Tenders are invited by the Manchester Board of Guardians for the installation of electric lighting at their offices in New Bridge Street. Particulars from the Clerk, and tenders by June 15th.

MIDDLESBOROUGH.—Block of offices. Architects, Moore & Archibald, 27 Albert Road, Middlesborough.

RHYL.—Hospital. Architect, P. Waterhouse, Staple Inn Buildings, Holborn, W.C.

STALYBRIDGE.—School, Waterloo Road (£9,452). Architect, G. Rowbottom, Portland Chambers, Stalybridge.

SWANSEA.—Roller skating rink, East Burrows Yard. Messrs. Jackson, Rochdale.

Technical college (£750). Builders, J. & F. Weaver, Manselton Steam Joinery Works, Swansea.

WREXHAM.—Alexandra Schools (£3,700). Architects, Burrell & Willey, Market Place Chambers, Durham.

Digitized by Google

TENDERS RECEIVED AND ACCEPTED

CLECKHEATON.—The tender of Messrs. Siemens Bros. & Co., Ltd., has been accepted for the supply of cables for tramway purposes at £723.

HULL.—The Telephone Committee have accepted the tender of the British Insulated & Helsby Cables, Ltd., for new cable at £253. A German firm quoted a lower price, but the committee decided to give the order to an English company.

LONDON: *London County Council.*—A contract has been placed with Messrs. Dick, Kerr & Co. for the supply and laying of pipes for cables across Blackfriars Bridge in connection with the working of the tramways from the Victoria Embankment. The estimated cost is £1,200.

A tender has been placed with Messrs. Reid Bros., for the laying of cable ducts between St. George's Circus and Blackfriars Bridge, and between St. George's Circus and Westminster Bridge. The estimated cost of laying is £3,500. About 40,000 ducts will be required, of which 25,000 are to be taken from stock, and the remaining 15,000 purchased at £9 per 1,000.

Marylebone.—The Council have accepted the tender of Mr. Haydn Harrison for 1906 twin lamp lanterns and 23 triple lamp lanterns for the conversion of street lamps to electric lighting. The details of the contract are as follows:—Fittings for twin lamp lanterns, 12s. 3d. each, fixing on site 3s. 6d.; fittings for triple lamp lanterns, 16s. each, fixing on site 4s.; wooden rods for turning on and off, 1s. each; spare parts: complete switch in chamber, 5s. 6d.; sealing chambers, 1s. 9d.; reflectors, two-light, 3s. 9d., three-light, 6s. 6d.; enclosed fuse carriers, 4d. each.

Southwark.—The Council has accepted the following tenders for ampere-hour meters:—The Electrical Co., Ltd. (4s. extra for self-adjusting brushes), 5 amperes, 25s.; 10 amperes, 25s.; 15 amperes, 29s. Gillespie & Beales, 5 amperes, 31s.; 10 amperes, 32s.; 15 amperes, 38s. Venner & Co., 50 amperes, 54s.; 100 amperes, 63s.

PARTICK.—Messrs. Siemens Bros. Dynamo Works, Ltd., have received a contract for the supply of carbon filament lamps and tantalum lamps to the Council.

SOUTHEND.—The tender of Messrs. Callender's Cable & Construction Co., Ltd., has been accepted for the supply of single conductor cables.

SUNDERLAND.—The tender of Messrs. Crompton & Co. has been accepted for the supply of arc lamp carbons for the ensuing six months.

YORK.—With reference to the notice in our last issue that the Corporation had accepted the tender of Messrs. Dick, Kerr & Co. for the construction of tramways, it appears that since the tenders were received Messrs. Dick, Kerr & Co. have written reducing theirs by £300 owing to a mistake having been made in a certain specification. This was put before the Corporation at its last meeting, when it was moved that the tender of Messrs. Dick, Kerr & Co. for carrying out the electrical portion only of the work should be accepted, and that of Messrs. Stark & Co., of Glasgow, for the permanent way. It was stated that if this were done there would be a saving of £1,200 over the combined tender of Messrs. Dick, Kerr & Co. After some discussion the matter was adjourned until the June meeting of the Council.

COMPANIES' MEETINGS AND REPORTS

MUSSELBURGH & DISTRICT ELECTRIC LIGHT & TRACTION CO.—The report shows a net balance of £4,024. Deducting debenture interest for the year and interest paid, less interest received, £2,412, there is a balance of £1,611. The directors recommend appropriating to reserve and renewals fund—tramways £400, lighting £200, paying a dividend on the preference shares for the year at the rate of 2 per cent. £880, and carrying forward £131. The profits show an increase of £169, of which the tramways are responsible for £125, and the lighting undertaking £44, compared with the previous year.

LEWES & DISTRICT ELECTRIC SUPPLY CO.—The report for 1908 states that the capital expenditure during the year amounted to £3,671, making a total capital outlay of £30,206. The gross revenue amounted to £2,294, being an increase of £202 over the preceding year. Expenditure amounted to £2,065, leaving a profit of £229, which, added to the sum of £54 brought forward from the previous account, makes an available balance of £283. The directors recommend that there be placed to depreciation and renewals account £250, carrying forward £33.

BERGMANN ELEKTRICITATS-WERKE AKT.-GES., BERLIN.—At the general meeting, the report, which recommended a dividend of 18 per cent., was adopted. Further shares to the value of 10 million marks are to be issued. The contracts obtained in the first four months of this year exceed those of the corresponding period of last year by three million marks.

HARTMANN & BRAUN AKT.-GES., FRANKFURT.—The report for the past year shows a reduction in the net profits, and in consequence a dividend of 11 per cent., as against 12 per cent. for the previous year, is recommended.

KORTING & MATHIESEN AKT.-GES., LEIPZIG.—At the general meeting, the report, recommending a 20 per cent. dividend, was adopted. The report states that the payment of this high dividend is rendered possible in spite of a considerable falling off of business in all branches, on account of the economies practised in previous years in the form of the building up of a large reserve fund, &c.

KALGOORLIE ELECTRIC POWER & LIGHTING CO.—The report for 1908 shows a profit of £21,644. The directors have allocated £7,500 to reserve for depreciation; debenture interest absorbs £2,156; preference dividends £9,000, and 4 per cent. dividend on the ordinary shares, £1,250. After meeting dividend tax in Australia, the sum of £1,226 is carried forward.

At the meeting on Thursday, the report and accounts were adopted. It was stated that although a new generating set had been installed out of the funds in hand, additional plant was required in order to meet the increased use of electricity at the mines. This, however, the Chairman stated, involved the question of raising new capital, and was a matter to which the directors would give their careful consideration.

SUBMARINE CABLE TRUST.—The report for 1909 states that the revenue amounted to £25,433 and the expenses to £1,167, leaving a balance of £24,315, including £49 brought forward. After providing £18,105 to meet payment of the coupons, the sum of £5,982 has been transferred to the redemption fund, leaving £228 to be carried forward.

RANGOON ELECTRIC TRAMWAY & SUPPLY CO.—The report for 1908 states that during the year an additional 1,500-kw. turbine has been installed. The municipal street lighting was finally completed on July 1st, 1908. The company have just been granted a licence by the Government of Burma to light the military cantonments of Rangoon. The gross profits for the year amount to £26,119, and after deducting expenditure and adding the balance from last account, there is a balance available of £13,856. After deducting preference dividend to Dec. 31st, 1908, and preliminary expenses written off, the balance carried forward is £383.

At the meeting last week, the report and accounts were adopted. It was stated that the proportion of expenditure to receipts was 60 per cent., but it was hoped to get this down to 50 per cent. in the current year.

WINCHESTER ELECTRIC LIGHT & POWER CO.—At an extraordinary meeting recently the articles of association were amended, by which the directors' fees may be increased to £400 per annum.

CALCUTTA ELECTRIC SUPPLY CORPORATION.—The net profit for 1903 amounted to £58,188, compared with £57,275 for the previous year. Adding the balance brought forward, namely, £4,160, and deducting the interim dividend on the ordinary and preference shares, &c., there remains an available balance of £41,668. The sum of £15,000 is allocated to depreciation and renewals, and a final dividend of 9½ per cent. is recommended on the ordinary shares. The number of units sold during the year was 6,765,792, an increase of 25 per cent. over 1907.

DIESEL ENGINE CO.—The accounts of the year ended March 31st show a balance of £21,275, including £5,919 from last year. A dividend of 10 per cent. is recommended, the sum of £5,000 is added to general reserve, and £6,275 are carried forward.

WEST AFRICAN TELEGRAPH CO.—The report for 1908 states that the revenue amounted to £56,316, from which is deducted £16,682 for the ordinary expenses, and £8,147 for expenditure relating to maintenance of cables, leaving £31,487, to which is added £831 brought forward, making a total available balance of £32,318. The sum of £1,343 has been provided for income tax, £20,000 has been transferred to general reserve fund, and an interim dividend of 2 per cent. (free of income tax), absorbing £4,622, was paid on December 1st last. The directors now recommend a final dividend of 2 per cent. free of income tax, making, with the interim distribution, 4 per cent. for the year, the balance of £1,731 being carried forward.

At the meeting last week, the report and accounts were adopted.

WESTERN TELEGRAPH CO.—The report and accounts for the half-year ended Dec. 31st, 1908, states that the revenue amounted to £343,668, and the working expenses to £133,673. After providing for debenture stock interest and for income tax, there remains a balance of £188,333; to this is added the sum brought forward, making a total of £192,593. First and second interim dividends have been paid, and after transferring £100,000 to the general reserve fund, £5,000 to the maintenance ships' reserve fund, £10,000 to the marine insurance fund, and £10,000 to the land and buildings depreciation fund, there remains a balance of £5,214 10s. 4d., which is carried forward to the next account.

At the meeting last week, the report and accounts were adopted.

Digitized by Google

EASTERN TELEGRAPH CO.—The report and accounts for the six months ended Dec. 31st, 1908, shows that the revenue for the period amounted to £566,100, and after deducting ordinary expenditure and expenditure relating to maintenance of cables, &c., there is a balance of £312,458, to which is added £53,765 brought forward. After providing for income tax payable in England, interest on mortgage debenture stock, and dividends on the preference stock, there remains a balance of £284,434, out of which the directors have placed £70,000 to the general reserve fund, and have paid an interim dividend of 1¼ per cent. on the ordinary stock. The directors now recommend the declaration of a final dividend on the ordinary stock of 1¼ per cent. and a bonus of 2 per cent., making a total distribution of 7 per cent. for the year. It is proposed to carry forward the balance of £34,434.

At the annual meeting last week the report and accounts were adopted.

BRITISH WESTINGHOUSE ELECTRIC & MANUFACTURING CO.—At the annual meeting on Monday, the report and accounts given in our issue for May 20th were adopted. Mr. J. Annan Bryce, deputy chairman, who presided, pointed out that the falling off of trading profit was due to universal depreciation in business. With regard to the item in the accounts of completed contracts, he said there was several old matters still in dispute, the most important of which was in connection with a contract dated 1901 with the Underground Electric Railways Company of London, Ltd., under which machinery was supplied to the Chelsea power house. The amount involved was large, but as the question had been referred to arbitration it was inexpedient to discuss it at present. Any losses resulting from the settlement of these matters must be charged to revenue, as no reserve had been provided therefor. Dealing with the general position and prospects of the company, he stated that a comparison of the results of the past four years led the directors to the conclusion that the many changes and improvements which had been made had resulted in a marked increase in efficiency, and that notwithstanding the heavy handicap of a large plant, restricted volume of business, and severe cutting of prices, the accounts showed that the percentage of gross profit returned on the apparatus manufactured had been satisfactory. With regard to the future, at present the manufacturing power of Great Britain was largely in excess of the demand of the home markets, and the hope of an increased volume of orders depended on the possibility of a larger export business, and an extension of the company's trading territory, proposals for which had been laid before the American house. For the moment, however, the export business did not offer any great prospect owing to the results of the American financial crisis of 1907. There were, however, signs that the wave of depression was passing away, although it might be doubted whether the position of the electrical industry in Great Britain would become permanently sound until British purchasers realised the advantages of standardisation.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £60 15s. to £61 5s. (last week, £60 10s. to £60 15s.).

BANKRUPTCIES, LIQUIDATIONS, WINDINGS UP, &c.—The General Electric Sign & Engineering Co., Ltd., is to be wound up voluntarily.

The last day for receiving proofs in the bankruptcy of G. Sutcliffe, electrical engineer, 22 Church Street, Abertillery, Monmouthshire, is June 10th. The trustee is Mr. E. F. Gardner, 144 Commercial Street, Newport, Mon.

A meeting of the Cornwall Electric Power Syndicate, Ltd., will be held at 3 London Wall Buildings, London, E.C., on June 29th, at 10.30 a.m., to hear the liquidator's account of the winding up.

The La Capital Tramways Co., Ltd., is to be wound up voluntarily. A meeting of the creditors will be held at noon to day, Thursday, at 62 London Wall, London, E.C.

Messrs. F. W. Pixley and H. Allen, of 58 Queen Street, London, E.C., have been appointed liquidators of the Amalgamated Radio Telegraph Co., Ltd.

The statement of affairs in the failure of Messrs. Middleton & Co., electric wiring contractors, of 11A King Street, Dover, shows gross liabilities of £789, of which £771 are expected to rank for dividend. The deficiency, including rates and taxes, is £789. The cause of the failure is "want of capital and heavy expenses in conducting the business."

An application was made in the Bradford County Court last week, for the discharge from bankruptcy of W. T. Garnett, trading as Garnett's Cable Co., of Barker End Mills, Bradford. The liabilities amounted to £31,329. A first dividend of 3s. in the £ has been paid, and there is a prospect of a further dividend of 1s. in the £. In granting the discharge, subject to the usual suspension for two years, Judge Graham stated that it was only fair to the bankrupt to say that after an investigation of his affairs he found nothing that reflected dishonour upon him.

DISSOLUTION OF PARTNERSHIP.—The partnership between E. H. Johnson, A. R. F. M. Reinhardt, A. J. Grose, R. Niepel, and J. M. Bein, under the style of the E.M.F. Manufacturing Company, at 10 Ironmonger Lane, in the City of London, has been dissolved.

MESSRS. VICKERS, SONS & MAXIM'S LONDON OFFICE.—We are informed that in view of the growth of their electrical business, and for the greater convenience of their customers in London, Messrs. Vickers, Sons & Maxim, of Sheffield, have appointed a representative at 28 Victoria Street, S.W. This branch of the business will be under the management of Mr. C. S. Thomson, M.Sc., M.I.E.E., who will deal with the large range of electrical machinery made at the Sheffield works, and also the smaller motors and generators manufactured by the Electric & Ordnance Accessories Co. at Birmingham, under the control of the Vickers Co.

SMALL TRANSFORMERS.—The Brockie Pell Arc Lamp Co. (Wimbledon) inform us that they are putting a new pattern of auto-transformer for metal filament lamps upon the market. The connections are made in a readily accessible porcelain chamber under a cast-iron cap at the transformer, and the windings are enclosed in a well-ventilated cast-iron cover forming the completion of the case.

NEWALL ENGINEERING CO.—In October last we notified a change of proprietorship in the business of the Newall Engineering Co., and mentioned that the works and offices would be removed to Blackhorse Lane, Walthamstow. This removal is now completed, the new factory fully equipped and running, and all arrangements satisfactorily made for continuing, on improved lines, the production of those articles associated with the Newall name, and of such additions to standard products as may, from time to time, be found requisite for satisfying the needs of engineering firms whose attention is now being more closely given to the questions of gauge and toolroom equipments.

FOR SALE.—The Dundee Corporation have for sale two continuous-current generating sets and four Lancashire boilers. See advertisement on another page.

The Locksbrook engineering works of Messrs. Kramos, Ltd., will be sold by auction on Tuesday, June 15th, at 11 a.m. Further particulars in an advertisement on another page.

COWPER-COLES ENGINEERING CO., LTD.—As announced in our last issue, a new Company has been formed entitled "The Cowper-Coles Engineering Co., Ltd.," with a working capital of £40,000, and its offices are at Grosvenor Mansions, 82 Victoria Street, S.W. The objects of the Company are to develop the business of Sherard Cowper-Coles & Co., Ltd., and to carry on the work of electro-metallurgists and chemical engineers. The Company will have a large exhibit of their special products, machinery, and apparatus at the London International Exhibition.

APPOINTMENTS AND PERSONAL NOTES

The successful candidate for the post of assistant to the Mains Engineer of the Birmingham Corporation Electricity Department is Mr. E. C. Jennings, who is at present with the British Thomson-Houston Co., Ltd.

Mr. C. S. Thomson, formerly Superintending Engineer to the Brush Co., and for the last six years connected with the export business of the British Westinghouse Co. in London, has severed his connection with the latter, and has taken up the position with Messrs. Vickers, Sons & Maxim, announced in another column.

MISCELLANEOUS CITY NOTES

CHIPPING NORTON & DISTRICT ELECTRIC LIGHT & POWER CO.—A prospectus for £1,500 5 per cent. first mortgage debentures at 96 per cent. was issued last week.

ALUMINIUM CORPORATION.—In the Companies' Winding-up Court last week, a scheme of arrangement was sanctioned on the petition of the company and the liquidators. It was explained that the company was incorporated in 1907 with a capital of £500,000 in 440,000 preference shares and 60,000 ordinary shares. There is a debenture mortgage to the bankers of £24,192, and the proposal was to pay the bankers in full, and to treat the vendors' liens as secured debts.

DEMERARA ELECTRIC CO.—The capital of this company has been reduced from £170,000 to £85,000.

Telegraph Traffic.—The submarine cable between Dakar and Conakry ceased working on the 13th inst., and the cable between Tangier and Cadiz broke down on the 19th inst. The cable of the West India & Panama Telegraph Co. between Jamaica and Colon is once more restored to working order. The telegraph lines of the Indo-European Co. were repaired on the 21st inst. Telegrams for other than coast stations in Venezuela are only accepted at senders' risk. The stations referred to are Caracas, Coro, La Guayra, and Puerto Cabelio. The *Times* Publishing Co. is complaining of the action of the Canadian telegraph companies in charging private message rates on all Press messages to Glace Bay intended for transmission by Marconi wireless. It is stated that this is not only injurious to the newspaper publishers, but also defeats the object the Government of Canada had in view in lending financial assistance towards establishing the Marconi wireless at Glace Bay.

INSTITUTION OF ELECTRICAL ENGINEERS

Annual Meeting and Report

At the annual general meeting of the Institution of Electrical Engineers, held on Thursday last, the Officers and Council for the ensuing session, nominated by the Council, of whom a list with a few biographical notes and portraits was given in ELECTRICAL ENGINEERING, April 22nd, p. 363, were declared duly elected, as no other nominations had been sent in.

PREMIUMS.

The following awards were announced:—

Mr. J. H. RIDER, the Institution Premium (£25), for his Paper on "The Electrical System of the London County Council Tramways."

Messrs. L. ANDREWS and R. PORTER, the Paris Electrical Exhibition Premium (£10), for their Paper on "The Use of Large Gas Engines for Generating Power."

Messrs. W. CRAMP (member) and B. HOYLE (student), an Extra Premium (£10) for their Paper on "The Electric Discharge and Production of Nitric Acid."

Mr. T. SWINDEN, an Extra Premium (£10) for his Paper, "Researches on the Magnetic Properties of a Series of Carbon Tungsten Steels."

Mr. E. A. WATSON (student), an Extra Premium (£10) for his Paper on "The Dielectric Strength of Compressed Air."

Mr. H. S. HALLO, an Extra Premium (£5) for his paper on "The Theory and Application of Motor Converters."

Messrs. J. C. MACFARLANE and H. BURGE, an Extra Premium (£5) for their Paper on "Output and Economy Limits of Dynamo Electric Machinery."

Mr. J. S. PECK, an Extra Premium (£5) for his Paper, "Flywheel Load Equaliser."

Messrs. C. C. PATERSON and E. H. RAYNER, an Original Communication Premium (£10) for their communication, "Non-inductive, Water-cooled Standard Resistances for precision Alternating-Current Measurements."

STUDENTS' PREMIUMS.

Messrs. B. E. STOTT and J. HARGROVE (Manchester), A First Student's Premium (£10), for their Paper, "The Design of Small Direct-Current Machines"; Mr. L. H. A. CARR (Manchester), a Second Student's Premium (£5), for his Paper, "Notes on the Elimination of Sparking." Three Extra Students' Premiums, each of the value of £5, were also awarded to Mr. P. C. JONES (Manchester), for his Paper on "The Single-Phase Railway"; to Mr. W. S. LONSDALE (Singapore), for his Paper on "The Direct-Current Variable-Speed Motor and its Application to Modern Machine Tools"; to Mr. C. S. RICHARDS (Manchester), for his Paper on "The Utilisation of Exhaust Steam for Electric Driving."

SCHOLARSHIPS.

Mr. J. MOULD, Salomons Scholarship (£50); Mr. H. MAXWELL-BROWN, David Hughes Scholarship (£50).

BENEVOLENT FUND.

On December 31st, 1908, the capital account of the Fund stood at £3,000, as compared with £2,735 9s. 11d. at the end of 1907. The donations to the Fund in 1908 include one of £105 from Mr. W. B. Esson, and another of £75 from the Committee of the Electrical Engineers' Ball. The Wilde Benevolent Trust Fund stands at £1,744 16s.

THE NEW INSTITUTION BUILDING.

The purchase of the lease of the site and building on the Victoria Embankment at £50,000 and a ground rent of £2,201 is to be completed by June 1st. For the present the Institution will occupy the whole of the ground floor and a portion of the first floor, which will form a Library, of nearly 3,000 sq. ft., facing the river. It is proposed to enlarge the Entrance Hall and the Lecture Theatre. The remaining portion of the building has been let for three years to the present owners, the Royal Colleges of Physicians and Surgeons. It is expected that the Institution will be transferred to the new building in the autumn, and that the enlarged Theatre will be available early in 1910.

MEMBERSHIP.

The Annual Report of the Council records an increase of the total membership (including students) from 6,068 last year, to 6,097. The number of full members has increased by 43, and of associate members by 193, but there have been slight decreases in the totals of associates, students, and foreign members.

WIRING RULES.

A new edition of the Institution's wiring rules, containing certain modifications to meet the new Home Office Regulations, and to permit of less expensive systems of wiring being used, is in course of preparation.

EXAMINATIONS FOR ASSOCIATE MEMBERSHIP.

The Council are considering the question of requiring candidates for Associate Membership to pass a qualifying examination.

ANNUAL ACCOUNTS.

The report of Mr. Robert Hammond, the Hon. Treasurer, shows that the balance carried to the General Fund at the end of 1908, being excess of income over expenditure, was £3,253 9s. 3d., as compared with £3,678 9s. 2d. for 1907. From the balance sheet it is seen that the total assets amount to £51,552 11s. 1d., against which are to be set liabilities amounting to £1,064 19s. 5d., leaving as the net assets of the Institution £50,487 11s. 8d. The following increases are reported in special funds: Entrance fees, £701 17s.; building fund, £1,219 11s. 2d.; general fund, £3,253 9s. 3d.; total, £5,174 17s. 5d.

Institution of Electrical Engineers.—The following is the result of the ballot of new members at the meeting on Thursday:—Associate Members: C. Beech, W. H. Brownjohn, B. E. Bumpus, W. E. Butcher, E. L. Castle, H. S. Davidson, T. H. Dennis, J. Dubbin, J. L. Duus, A. W. Empson, M. Fitzgerald, J. A. Forde, A. G. Fox, J. Graham, W. V. Haslam, W. Hockley, W. Jamieson, E. G. Lunn; C. E. May, T. May, R. E. Parnham, F. W. Peasnell, A. E. A. Ridgway, P. M. Robinson, J. A. Shaw, R. Stockbridge, T. P. Strickland, C. W. Thompson, T. E. Turner, H. S. Walker, W. R. Warren, H. L. Williams, B.A. Associates: W. Murray, R. Robertson, H. C. Stoddart, H. R. Todman. Students: W. K. Burke, Nanigopal Mukerjee, W. H. Walton, T. M. Wheeler, E. Whitehouse.

Use of Electric Oscillations in Surgery.—A sensational paragraph headed "Surgery by Wireless" appeared recently in the *Daily Mail*, and described an apparatus designed by Dr. Horace Manders for the employing of "wireless currents" for the removal of diseased growths. The apparatus referred to is one for utilising the heating effects of the high-frequency spark discharge. Dr. Manders obtains a sustained oscillatory discharge between sparking points of zinc and aluminium, and from this feeds a transformer. In consequence of the sustained oscillations the heating effect of the sparks are enhanced, and as they are quite short the action is limited to the point where the electrode is applied. If a small-bladed knife is used as the electrode, and this is moved along the line of the proposed operation wound, the streams of sparks burn away the tissue in such a way that an effect like that of a cutting operation is obtained, but without any bleeding, as the heat sears the blood vessels. The edge of the knife should not be in actual contact with the tissues, but at a distance of a millimetre or two from them. The heating effect being confined to the actual spark, it is very localised, and there is no general burning of the tissues, which seem cut as with a knife.

Extension of the Central Battery System.—On May 15th the National Telephone Co. transferred the subscribers to its Dalston Exchange (London) and its Rusholme Exchange (Manchester) to the C.B. equipment. Both equipments were manufactured and installed by the Western Electric Co., of North Woolwich. The Dalston Exchange has been transferred to new premises, which have been specially designed. The new equipment is of the No. 1 C.B. type, consisting of 18 subscribers' positions, giving accommodation for 2,020 lines, and eight in-coming junction positions. The ultimate capacity of this type of switchboard is 10,000 lines. There are no features embodied in the Dalston equipment which call for special comment, it being of similar design to that installed at the company's Birmingham Midland and Hillhead Exchanges. (A full description of the Birmingham Midland Exchange appeared in ELECTRICAL ENGINEERING of March 4th, 1909.) The new equipment of the Rusholme Exchange is of the No. 10 C.B. type, and has seven subscribers' positions, giving accommodation for 900 lines, and four in-coming junction positions. The ultimate capacity of this type of switchboard is 1,600 lines. The characteristic features of the No. 10 type of switchboard were outlined in a short article relating to the Great Yarmouth Exchange, which appeared in ELECTRICAL ENGINEERING of March 11th, 1909 (p. 230).

THE G.B. SURFACE-CONTACT SYSTEM ON THE L.C.C. TRAMWAYS

Mr. Mordey's Final Report

IN ELECTRICAL ENGINEERING, April 22nd, p. 375, we published extracts from a series of reports of Mr. Mordey, who was called in by the London County Council to investigate the practicability of continuing the service on the Aldgate–Bow tramway line, which had been equipped on the G.B. surface-contact system, and overcoming the difficulties which had led to the suspension of running. We have now received from the G.B. Surface Contact Co. a copy of the last report, dated April 5th, which was submitted to the Council just before the meeting at which the abandonment of the scheme was finally decided upon.

In this report, Mr. Mordey writes as follows:—

I am obliged for the copy of the report of the Highways Committee, and note that the Chief Engineer and the Chief Officer of the Tramways are of opinion that the experiments so far carried out do not satisfactorily remove all the objections which they brought to your notice in July, 1908, and as the result of which they recommended the discontinuance of the system. I have again examined the reports of these officers, dated respectively September 1st and August 26th last, and now enclose the Chief Officer's statement of defects with my notes thereon. I refer in the same way to the two main defects referred to in the Chief Engineer's statement. You will see that all the points have been dealt with except one or two which, as already reported, I did not consider it necessary to deal with at this stage, as they presented no difficulty or uncertainty. I am sorry I have not had an opportunity of going over these points in detail, either with the Committee or with the officers in question, as I am sure it would only have been necessary to examine them one by one to dispose of them. The trial runs have been few and short in duration, but as they showed that the main difficulty was overcome, and as they revealed nothing that was not obviously capable of easy remedy, I did not think it necessary to delay making my recommendation, believing that ample opportunity would be found for clearing up the two outstanding points.

The summary of defects sent by the Chief Officer of Tramways to Mr. Mordey on August 26th, 1908, and referred to above, is given below, with Mr. Mordey's notes regarding each point raised in italics:—

BROKEN STUD HEADS.

Causing cracked stoneware T pieces through which water and other matter leaks, thus making the studs sticky in action, so that when a car passes they either remain dead or alive. [*Using cast steel instead of cast iron will prevent breakage. In trial* 1,000 T *pieces examined—more than* 100 *slightly cracked, but only one had allowed water or other matter to leak in.*]

In several instances the shank of the stud under the head was found broken. [*This can be prevented by suitable adjustment of the head.*]

In a few cases the cement joint between the T piece and the cable pipe became defective, probably due to the vibration of the heavy traffic. [*No such case found on trial track.*]

LEAKAGE BETWEEN STUD HEAD AND RAIL.

Causing:—(1) Live studs, the circuit being maintained through an arc between the carbon contact and the cable by leakage from the stud head to the rail through wet road refuse. [*These live studs are now prevented.*] (2) Excessive leakage to earth during adverse weather conditions. [*This leakage is quite unimportant so far as cost is concerned. On the average it is certainly not as much as* 1/50*th of a penny per car mile.*]

DEFECTS IN STUD MECHANISM CAUSING LIVE STUDS.

Defective enamelling on "knock-on" causing rust and consequent stickiness. [*No such case found on trial track.*]

Some of the trouble in the studs was probably due to the small current-carrying capacity of the leads. [*Tests already reported show current-carrying capacity sufficient. Further borne out by condition of studs on trial track.*]

Destructive effect of gas generated when arcing took place between the carbon contact and cable. [*No evidence of this found. In any case, arcing, which is supposed to cause it, is now prevented.*]

Insulators to which springs were attached found broken. [*Prevented by small insulators of improved design at the cost of less than* 1*d. each.*]

Flexible leads getting jammed between the spring and the guide. [*None found on trial track—might be caused occasionally by arcing, which is now prevented.*]

Stickiness in studs, probably caused by carbon deposit and moisture. [*Absence of arcing and reasonable drying of conduit will prevent this.*]

RESISTANCE STUDS.

Not properly designed for current which they had to carry. Unsuitable design of stoneware T piece, making it most difficult to connect up stud, even with a very small lead. [*Both these avoided by proposed modification of special work.*]

ACCESS BOX COVERS.—[*These have been already partly dealt with. They present no serious difficulty.*]

VENTILATION.—[*Already reported on. This presents no difficulty.*]

SKATES.—The Chief Officer's statement, after referring to preliminary difficulties, proceeds:—"The cars inspected by the Board of Trade—and all cars subsequently run in service were fitted with two three-coil skates. The great disadvantage of this arrangement was that the magnets absorbed an abnormal amount of energy. [*The energy absorbed is now less than that taken up by one* 16 *c.p. lamp.*]

The G.B. Company were requested to submit a design for a two-skate equipment which would allow for the necessary gap for the plough carrier between the two skates. This design has, I believe, been prepared, but whether this would give any better results than those obtained from the skate equipment originally designed by the G.B. Company is extremely doubtful. [*It is a great improvement. It halves the energy, and doubles the speed.*]

Great disadvantage of the two-skate equipment would be that each stud would be operated twice when a car was passing. [*This seems to give rise to no difficulty, but in report of March* 31*st, I point out that one of the collectors can very probably be dispensed with altogether.*]

DEFECTS IN COLLECTOR SKATES.

Being insulated with wood sheathing, the water and mud permeates the fibres, and causes electrical leaks of considerable magnitude during wet weather. The large area of highly magnetic metal under each car is responsible for the collection of a large quantity of metal débris, resulting, in some cases, in very serious short-circuits. [*Greatly improved results should be obtained with the new design. No trouble met with in trial run.*]

The magnet must of necessity be carried close to the level of the road; consequently any displacement of setts or wood block paving results in the fouling of the skate therewith, and breakage of the equipment. [*Risks from this cause are very slight with the L.C.C. standard of paving.*]

Breakage of the collector chains in service, resulting in short circuits and damage to equipment generally. [*I agree, and had arranged for steel instead of cast-iron chains. This would prevent breakage.*]

Electricity versus Gas for Church Lighting.—Mr. P. J. Pringle (Borough Electrical Engineer, Burton-upon-Trent) sends us particulars of the saving that has been effected in a church in that town by the substitution of electric light for gas. It appears that the church referred to was previously lit up by 12 coronals of fish tail burners, each coronal having 24 burners, but the whole of these burners were not in use. The lighting is now carried out by 75 "Osram" lamps of 25-c.p. each. It is stated that the electric light bill for two quarters amounted to £3 10s. 8d., against £13 7s. 7d. which had been paid for gas for the corresponding period of the previous year.

An Electrical Musical Instrument.—An instrument, in which vibrations of strings are produced by electromagnetic influence, has been devised by Messrs. M. L. Levey and G. B. Sinclair, of Boston. It is claimed that as the vibrations of the strings are produced without mechanical contact such as that of a bow, a much more complete series of overtones results, as the strings are free to pulsate from end to end. According to the *Electrical World* (New York), rich full tones are produced. The instrument has been named the choralcelo, and is controlled from an ordinary keyboard, which actuates suitable contacts. The volume of sound is sufficient to fill a large hall, and the current consumption is said not to exceed 6 amperes at 110 volts.

Dublin Section of the Institution of Electrical Engineers.—At the annual meeting last week the following were elected officers of the Dublin Local Section of the Institution of Electrical Engineers for next session:—Chairman, Wm. Brown (Royal College of Science, Dublin). Vice-chairman, Wm. Tatlow. Committee, A. Hosgood (Assistant Electrical Engineer, Pembroke Council), S. T. Land (Assistant Electrical Engineer, Rathmines Council), S. L. R. Price (Electrical Engineer, Pembroke Council), M. Ruddle (Chief Electrical Engineer, Dublin Corporation), P. H. Stewart (Electrical Engineer, Messrs. A. Guinness, Son and Co.), R. N. Tweedy (Messrs. W. Coates and Son), A. W. Wheldon (Chief Electrical Engineer, Great Northern Railway Co. of Ireland), G. F. Pilditch (Electrical Engineer, Rathmines Council), P. S. Sheardown (Electrical Engineer, Dublin United Tramways Co., Ltd.). Hon. Secretary, T. Tomlinson.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published May 20th, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

26,981/07. **Separation of Oxides of Nitrogen from Air.** Sir W. Ramsay. In the electrical manufacture of nitrates from atmospheric nitrogen the oxides of nitrogen present in the air that has been blown through the arc form a very small percentage of the total volume of gas. To concentrate and finally separate these oxides, the mixture is passed under pressure into a system of pipes surrounded by liquid air. The mixture condenses and is caused to flow down a fractionating column and meet the products of evaporation of the liquid air. Rectification takes place, and nitrogen escapes from the top of the column. The oxygen and the oxides of nitrogen are returned to the tank containing the liquid, but the oxygen is continually evaporating. When the oxides of nitrogen are sufficiently concentrated in the tank, the liquid is run off and evaporated, the gases being passed through a solution to form nitric acid or a nitrate. The oxygen is passed with fresh air to the electric furnace, and increases the percentage of oxides produced. In a modified arrangement the different gaseous constituents are separated by fractional liquefaction. Three claims, three figures.

9,222/08. **Multiple Carbon Arc Lamp.** C. A. Carpenter and O. T. Banks. In this lamp the clockwork mechanisms controlling the successive feeding of the different pairs of carbons are arranged in a row at the top of the lamp. The regulating lever, when lifted by the influence of the shunt coil, releases all the movements simultaneously, but each train of wheels is held by a separate locking tooth operated by a pin on one of the wheels of the adjacent mechanism. By this means the mechanisms are released in succession, the carbons being consumed one pair at a time. Shutters over the openings in the economiser roof prevent the carbons falling and touching, and when one pair is consumed the next pair is automatically released so as to touch, and short-circuit the burnt-out pair. The swinging and fixed guide frames are detachably mounted on the main frame. Four claims, two figures.

9,241/08. **Flame Arc Lamp Carbons.** A. D. Jones (Jandus Arc Lamp & Electric Co.). The flame carbon of the Jandus enclosed flame arc lamp has a fluted carbon core of star section, the chemicals being pasted in between the radiating ridges. According to this invention, these ridges are supplied with projections at their extremities, so as to hold in the paste mechanically. Three claims, five figures.

25,443/08. **Manufacture of Metal Filaments.** Dr. H. Kuzel. In the formation of filaments from colloidal mixtures, it is necessary to raise the threads to a white heat to destroy the colloidal formation and reduce them to pure metal filaments. It has been usual to perform this operation in an atmosphere of an inert gas at, or slightly below, atmospheric pressure, but the filaments produced in this way frequently contain cavities which, besides causing an irregular resistance, make the filaments liable to break. According to this invention, the heating is carried out in a stream of gas containing 20 per cent. of hydrogen and 80 per cent. of nitrogen at a pressure of about 30 mm. An absolute vacuum would be better, but is not practicable; the gases are kept flowing so as to prevent a harmful rise of pressure due to the gases given off by the filaments. Filaments formed in this manner are rarely porous, as the gases escape before cavities can be formed. The filaments are brought up gradually to a white heat, and are subjected to tension during the heating by hanging weights or other suitable means. The gases given off increase the pressure somewhat, but it should not rise above 150 mm. Five claims.

4,762/09. **Apparatus for Producing High-Frequency Oscillations.** Dr. W. Peukert. This consists of two polished metal discs spaced a very small distance apart. One disc is fixed and the other is rotated at a high speed. Oil is fed continuously between the discs, and a thin film is formed which prevents direct contact between the discs. If this oil gap is connected across an inductance and a capacity to form an oscillating circuit in the usual way, the resistance of the oil film will be alternately reduced by the electric stress across the gap, and restored by the fresh supply of oil, and oscillations will be set up in the circuit. The frequency will be fixed by the values of the inductance and capacity, and the amplitude will be constant if the speed and the supply of oil are regular. Two claims, two figures.

Opposition to Grant of Patent

1,777/08. **Live Steam Feed Water Heater.** G. Wilkinson. A patent has been granted on this application, in spite of opposition. Full particulars are given on page 480 of this issue.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

Arc Lamps: Mount and Beck Flame Lamp, Ltd. [Mounting and feeding of carbons] 15,346/08; Timar and Von Dreger [Lamp with tangentially arranged carbons] 27,143/08.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: British Thomson-Houston Co., and Wedmore [Distributing systems] 11,634/08; Lake (*Standard Varnish Works*) [Solid insulating compound] 16,885/08; Voigt & Haeffner Akt.-Ges. [Distributing stations] 22,562/08.

Dynamos, Motors, and Transformers: Prott [Control of motors] 4,950/08; Jackson [Control of motors] 7,335/08; Vidal and Vidal [Electric transmission of motive power] 14,312/08.

Electric Ignition: Wicke [Igniting device for miners' lamps] 9,662/08; Best [Apparatus for igniting miners' lamps] 10,838/08.

Electrometallurgy and Electrochemistry: Voelker [Electric furnaces] 28,276/08.

Incandescent Lamps: Westinghouse Metal Filament Lamp Co. (*Westinghouse Metalfaden Gluhlampen Fabrik-Ges.*) [Manufacture of tungsten filaments] 14,942/08; British Thomson-Houston Co. (*General Electric Co., U.S.A.*) [Supports for filaments] 23,069/08; Siemens & Halske Akt.-Ges. [Manufacture of tungsten filaments] 25,854/08, and 2,853/09; British Thomson-Houston Co. (*General Electric Co., U.S.A.*) [Manufacture of filaments] 3,951/09.

Storage Batteries: Boult (*Schlesische Akkumulatoren-Werke Akt.-Ges.*), 10,037/08; Fiedler [Plates] 24,224/08.

Switchgear, Fuses, and Fittings: Hilliard and Parsons [Switches] 9,756/08; Felten & Guilleaume-Lahmeyerwerke Akt.-Ges. [Automatic cut-out] 9,844/08; British Thomson-Houston Co. (*General Electric Co., U.S.A.*) [Electro-magnetically controlled switches] 14,967/08; Wilkins [Lamp adapters] 15,030/08; Snowdon [Switches] 17,142/08; Peyrusson [Insulation of switches] 22,426/08.

Telephony and Telegraphy: Cutmore [Telephone mouthpiece cover] 12,346/08; Rawdon [Telegraphic repeaters] 355/09.

Traction: Kordin [Stopping trains independently of driver] 9,571/08; Boult (*Union Switch & Signal Co., U.S.A.*) [Control of speed of trains] 11,804/08; Commin [Operating tramway points] 24,641/08; Busse [Tramway rails] 3,522/09; Mahoney and McCurdy [Magnetic brakes] 8,521/09.

Miscellaneous: Vaccaneo [Illuminated sign] 18,487/08; Centralstelle für Wissenschaftlich-Technische Untersuchungen-Ges. [Production of long arcs] 2,216/09; Schiessler [Electric condensers] 4,028/09.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Wolters [Electric safety lamps] 10,213/09; Pralon, Francon, and Fournier [Distributing electrical energy] 10,456/09.

Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: A. Kronstein [Acid- and water-proof insulating materials] 2,679/01; G. F. Mansbridge [Telegraph and telephone cables] 2,963/03.

Dynamos, Motors, and Transformers: B. G. Lamme and J. P. Mallett [Armature windings of A.C. machines] 15,138/99.

Electrometallurgy and Electrochemistry: R. Grisson [Electrolytic valve and condenser] 3,163/02; O. Rank [Ozoniser for sterilising milk] 2,593/04.

Instruments and Meters: G. Hookham [Mercury-disc meters] 2,683/96.

Switchgear, Fuses, and Fittings: B. N. Jones [Switchgear for push-button lift control] 2,939/02; A. D. Smith [Cartridge fuse] 3,116/02; J. R. Craig [Quick-break switch] 2,746/03; W. Kingsland [Traction controller mechanism] 2,774/03; G. Irving [Lamp pendant] 2,766/04.

Telephony and Telegraphy: G. Lambert [Central battery telephone system] 2,700/02; G. Lambert [Telephone jack] 2,701/02; W. Harrison [Aerials for wireless telegraphy] 17,484/04.

Traction: R. B. Ransford (*Soc. Anon. des Brevets Dolter*) [Junction boxes for use in surface-contact system] 2,394/01; Johnson-Lundell Electric Traction Co. (*J. G. V. Lang*) [Automatically released brakes] 2,564/03.

Miscellaneous: Siemens Bros. & Co. (*Siemens & Halske Akt.-Ges.*) [Watertight bells for mines] 2,357/00; W. M. Mordey [Adjustable choking coils to compensate for capacity in A.C. circuits] 2,384/00; W. J. Fowler [Electrically heated brush] 3,060/02; E. Weintraub [Mercury vapour rectifier] 2,580/04.

ELECTRIC DRIVING OF NON-REVERSING ROLLING MILLS

MR. W. F. MYLAN read a Paper on the "Electrification of Steam-Driven Non-reversing Rolling Mills" recently before the Leeds Section of the Institution of Electrical Engineers. He gave a list of some non-reversing mills now in operation in this country, driven by motors varying from 130 to 1,000 h.p., numbering thirty, and all except four employing three-phase motors. It is estimated that in Europe at the present date there are upwards of 230 electrically driven non-reversing mills in operation, the horse-power of the motors used exceeding a total of 200,000 h.p.

The author emphasised the necessity for considering every case separately in designing a suitable equipment for a mill, and pointed out some of the difficulties that are introduced owing to the change having to be made with the minimum interference with the working of the mill. The size of motor required may be estimated partly by means of a series of continuous indicator diagrams of the engine, but allowance must be made for the increased output and heavier duty required of the motor due to the higher average speed, with consequent greater output following on the more even torque exerted by the electric motor as compared with the less even turning effort of the steam engine. It is better, he said, to estimate the horse-power of the motor by calculating the work it will be called upon to do from the data already obtained under the same or similar conditions. Knowing the total output of the mill during a certain period, the nature, size, and section of the raw material; the size of the finished product; and the cycle of operations, it is possible by comparison with figures already known from other installations to estimate very closely the horse-power of the motor to be installed.

A properly designed flywheel is of great assistance in reducing the size of the motor and enabling it to get over the peak loads without absorbing too great a current from the line. The use of a flywheel for levelling the output demanded of the motor is not generally practicable if the time in rolling one pass exceeds about 30 seconds, and in such cases the introduction of a heavy flywheel would be open to very serious objections, inasmuch as the motor would, after a certain point in the pass, have to pull the flywheel round in addition to supplying the power required for rolling. This is the case in rolling long bars, rails, &c., and here a comparatively light flywheel is desirable, levelling only the smaller peaks and variations in the load, the motor being designed to deal with the main peaks without any external assistance. In those cases where a heavy flywheel is employed with the object of relieving the strain on the motor it is usual to employ an automatic device to ensure that the flywheel carries its fair share of the load. With direct-current machines the motors are always compounded, and to increase the strength of the field, further use is made of a separate excitation, which increases the field current, so reducing the speed still further and obtaining a return of the flywheel energy during the correct period. With alternating equipment a slip regulator is employed automatically, introducing a resistance in the rotor circuit at times of heavy load. The proper place for the flywheel is, of course, on the highest running shaft; but this is not usually feasible, and consequently it is generally found that the flywheel is fitted on a motion direct geared to the mill, thus preventing the extra strain on the motor and its gears or ropes. Flywheel equalisers are occasionally employed to level up the demands on the power supply, but these are open to the same limitation as the direct use of a flywheel.

In merchant mills it is an advantage and practically a necessity to be able to vary the speed of the mill motor. With a direct-current power supply this is a comparatively simple matter, by means of field regulation only. In such cases the efficiency of the motor is to all intents and purposes unaltered by variation in speed, but unfortunately the same cannot be said where the source of power is alternating-current. The only practical way of reducing the speed of an alternating-current motor is either by the introduction of resistance into the rotor circuit, or by choosing a suitable combination on the number of poles in the stator and distributing to stator winding to suit, to run at two, or, at the most, three, speeds with economy, these speeds being obtained according as the windings are connected to give one-half or one-third the normal number of pairs of poles.

The method adopted of transmitting the power from the motor to the mill rolls is worthy of careful investigation. In the large majority of cases it is impossible to direct couple the motor to the mill, and some form of speed reduction is essential. In such instances, however, where the motor can be direct coupled, it is advisable, with the view of reducing the sudden shocks and strains on the motor, to introduce a flexible coupling.

Owing to the heavy and frequent overloads that the motor must deal with, the shaft must be stiffened, and great care must be taken to see that the end windings of the motor are properly braced to prevent distortion. Where slip-ring motors are employed the rings should be of ample section. Occasionally one meets motors where the smallness of the rings has a serious effect in very much reducing the overload capacity of the motor owing to the smallness of the rotor currents, which can be dealt with without excessive sparking and heating at the rings. A circuit breaker should always be provided in the main circuit of the motor, the breaker being fitted with overload and no-volt release. The provision of a no-volt release is important, as this allows of the fitting of emergency switches at each housing and other suitable points, allowing the mill to be quickly stopped in case of necessity from any of several points. For starting large motors, the author favoured a liquid controller.

Particulars were then given of some mills which have been successfully converted from steam to electric drive. One of these was a cold rolling brass merchant mill, consisting of one set of breaking-down rolls, one set of second breaking-down rolls, and two sets of finishing rolls. The breaking-down rolls are 20 in. diameter, 30 in. long, and all are driven at 6 revs. per minute by a long train of gear-wheels.

The usual size of ingots dealt with in this mill are 3 in. × 1½ in. × 7 ft. These ingots are rolled down to various gauges, No. 8 being about the average and also the usual size. The ingot is first rolled into strip; this strip is then put through the cutting-up machine, resulting in pieces of rectangular section, which are then passed on to the draw benches to be drawn into ordinary brass wire.

In this case the motor is a 200-h.p. 25-period 400-volt 3-phase 240-revolution slip-ring motor, direct geared, by means of cast-iron gear, to the mill. The gear ratio is about 4·8 to 1, the gears being 3½-in. pitch and 12-in. face. The motor is fed from the secondary of a 3-phase 5,000 to 400-volt transformer. No flywheel is provided. Starting is carried out by a liquid starter, and a number of emergency switches are provided which open circuit the no-volt attachment on the primary oil-break switch. Another example mentioned was an iron and steel merchant mill rolling a large variety of sections, and consisting of 5 pairs of 12-in. rolls running at 80 revs. per minute as a minimum, driven through double helical steel gears, ratio 1 to 2·5. In this mill the 5 pairs of rolls practically comprise two mills having two gangs of men who work quite independently of one another. It thus often happens that several passes are made at the same moment, but as the motor is very generously rated no difficulty has been experienced through an exceptional load coming on and pulling up the motor. The supply in this case is direct current, and the motor has a normal output of 200 B.H.P. at from 200 to 450 revs. per minute. The machine is fitted with commutating poles, speed variation being obtained by the use of a field rheostat. As the rating of the motor is extremely liberal, overloads of 100 and 150 per cent. can be carried for fairly long periods without sparking or harm to the machine. Since the mill was electrified an increase of output of over 30 per cent. in material rolled and a decrease in the power consumed by 60 per cent. has been obtained.

An example of a sheet-iron mill is one being operated by a 350-B.H.P. slip-ring motor off a power company's supply. The mill has three pairs of housings of the two-high type barring, roughing, and finishing rolls, and deals on an average with 600-lb. blooms rolled into sheets 10 ft. × 4 ft. × $\frac{1}{16}$ in. The motor is designed to run normally at 400 revs. per minute when fed from a three-phase 40-period 400-volt supply. It is fitted with rope pulley 4 ft. 6 in. diameter arranged for twenty-two 1½-in. ropes, the outer end of the shaft being carried on a pedestal bearing, and the whole carried on a bedplate and slide rails. The control of the motor is effected by means of a hand-operated liquid starter and regulator, the controller being fitted with cooling coils. The motor drives by means of the ropes on to a second pulley 10 ft. 6 in. diameter and weighing 14 tons. The shaft of this pulley is geared to the mill ratio 1 to 3·75, giving a normal speed of the mill of about 45 revs. per minute. The gears are 17 in. face 4½ in. pitch. Since having had experience of the above it has been decided to equip electrically a second and larger mill at the same works.

Some figures were then given as to the current consumption

Digitized by Google

required for different classes of work. For example: girders 11 in. × 6 in. can be rolled for about 50 units per ton, channels averaging 1½ in. × ¾ in. × 0·02 in. require 66 units, sheets (iron) 8 ft. 3 in. × 33 in. × 0·064 in., 95 units per ton, and cut sheets 10 ft. × 48 in. × 0·125 in., 60 units per ton.

Among the advantages of electric driving is the possibility, owing to the steadiness of the torque, of running the mill at a considerably higher speed than formerly, and a better product with more uniform finish results, as well as a larger output. An increased output can also be looked for due to the convenient and rapid manner in which the mill can be controlled and handled.

The efficiency of the electrically operated mill, as estimated by the actual cost of rolling as compared with steam-driven mills, is beyond dispute. In this connection it should be borne in mind that the actual decreased power costs in rolling are not due so much to the fact that it is an electric motor doing the work, but that the electric motor enables one to either purchase power at low rates from one of numerous supply companies.

A very important advantage which follows on the introduction of electricity is the possibility of arriving at very exact figures of the actual power consumed under any conditions.

A very material saving in floor space is certain where a mill is converted to electricity, and this is a great advantage, as it enables the space around the mill to be used for the more rapid handling of the material required to feed the mill, and for the disposal of the finished product. Very often the motor can with advantage be installed below the floor level, the only gear on the shop floor being the comparatively insignificant control gear. An electrically operated mill has in any case less stand-by losses, and in the case of the motor fed from a supply company's main, none at all. Where a motor is employed for driving a mill a great advantage accrues through being able to start up immediately, and a further reduction in cost of rolling is obtained through less labour being required to handle the same material.

Finally, on the question of capital cost, speaking generally, the actual electrical equipment of a rolling mill is at the worst only equal to, and in the majority of cases considerably cheaper than, the corresponding steam equipment. If, however, electrification involves either the putting down of a generating plant or the extension of an existing plant, then there is no question that the electrification of the mill will entail the expenditure of a larger sum of money than that involved by putting down a new steam plant, and in such cases one must look in other directions to justify the conversion. Usually in any works having a rolling mill there are a great number of auxiliaries on which the existing drive can, with considerable economy, be replaced by one introducing the use of a motor, and it is the extra and more even load due to these motors that will justify the installing of a generating plant of capacity sufficient to carry the load on the mill, and in addition that due to the auxiliaries. It would be impossible to run a plant feeding one mill only, and generate with economy unless some other load less variable is also to be obtained, and consequently in such a case it is necessary to consider the broader scheme if any benefit from the electrification is desired. In the case of the works where a plant is already installed, and a comparatively cheap extension is all that is necessary, the problem is much simpler, and there is no difficulty in making out an excellent case for the electrification.

Diesel Engines for Generating Stations.—In our issue of last week, on page 476, Mr. W. H. Booth is reported to have given the fuel cost per b.h.p. hour in certain Diesel engine tests as having been 0·69d. at full load and 0·449d. at quarter load. This should have been that the cost was that of 0·69 lb. and 0·449 lb. of fuel respectively.

Birmingham and District Electric Club.—A Paper was read recently before the Birmingham and District Electric Club by Mr. W. Smith on "Illumination." In comparing different illuminants, the author gave the comparative cost of lighting by oil, gas, and electricity as in the ratios of 1, 0·46 and 1·1 respectively, taking paraffin oil at 9d. per gallon, gas at 2s. 3d. per 1,000 cub. ft., and electricity at 4d. per unit. In considering the amount of illumination required in rooms, he stated that one candle foot was about sufficient to enable the average person to read with comfort. A great deal depended on the colour and reflecting power of the decorations. In the course of some remarks upon workshop and exterior lighting, Mr. Smith referred to the glaring effects of powerful flame arcs outside shops, and suggested that Mr. Lloyd George might do worse than make these blinding annoyances a source of revenue. With reference to street lighting, he said that side streets should have something like 1 c.p. per 200 sq. feet of ground area, but that leading thoroughfares should be much more liberally supplied.

ELECTRICITY WORKS AND REFUSE DESTRUCTORS

Discussion in Dublin

THE Paper read by Mr. J. A. Robertson in April before the Glasgow section of the Institution of Electrical Engineers on "Combined Electricity Works and Refuse Destructors," was discussed by the Dublin section of the Institution on May 13th. In this paper, which, together with a report of the Glasgow discussion, was given at some length in ELECTRICAL ENGINEERING, April 22nd, p. 369, Mr. Robertson dealt fully with a number of points in destructor design, and gave the results of tests and of the first year's working of the plant at Greenock.

The Dublin discussion was opened by Mr. G. H. PILDITCH (Resident Electrical Engineer, Rathmines), who said that he was not altogether in favour of combined stations for several reasons, including the dust trouble, the fact that while it was best to burn the refuse continuously the demand for steam was very uneven, and the great variations in both the quantity and quality of the fuel. At Rathmines they had obtained good results from the combined plant, because they were able to make use of all the steam generated whenever it was available. An evaporation of 1·25 lbs. of water per lb. of refuse was obtained, and 35 to 40 units per ton destroyed, while steam was also supplied for the clinker crusher and forced-draught fans. The conditions were favourable to the use of a battery. At Rathmines, as at Greenock, owing to the electricity undertaking having been in operation for some time before the destructor, they were able to make a fairly close estimate of what the coal consumption would be if all the steam were still being obtained from coal-fired boilers, and the difference between the value of the coal actually used and the estimated value, as above, was taken as the value of the steam supplied by the refuse destructor.

Mr. S. L. R. PRICE (Electricity Works, Pembroke) thought that more might be done with financial advantage in the direction of clinker paving block manufacture, and instanced the case of Fulham. With regard to arrangement of cells, he favoured the arrangement in which the cells were isolated from one another, discharging their burning gases in parallel into a common combustion chamber, as giving a more even supply of heat to the boiler. It was also then easy to isolate a cell for repair. He had had bad experience of dampers, which led to bricking up the bypass with a dry wall, which was so arranged that it can easily be knocked down, if desired, in a few minutes. As there were two boilers, variations of steaming could be obtained by shutting off one or other, or allowing the gases to divide up and flow through both in parallel by means of the dampers *past* the boilers where the gases are spent and harmless. He estimated that the electricity department virtually saved the destructor quite £200 per annum, which amply repaid them for the steam supplied, adopting a similar basis of calculation to that set out in the Paper.

Mr. S. T. LAND (Assistant Engineer, Rathmines) had had satisfactory experience with the destructor at Canterbury of the Beauland and Deas type, in which the refuse was stewed on a drying hearth. Regarding the installation of a large battery in installations combined with a destructor, he agreed with the author that, as a rule, such a course was not as a rule advisable; but, as mentioned by Mr. Pilditch, the circumstances at Rathmines rendered such a procedure advisable. Mr. Land did not agree with the author's statement that refuse from coal-mining districts possessed a higher calorific value; at Wakefield, which was a mining district, the quality of the refuse was very much worse than at Canterbury, where coal was naturally expensive. The dust gaining ingress to the engine-rooms in all the combined undertakings with which he had been connected was not sufficient to cause trouble.

Mr. T. TOMLINSON said that the Paper should have been discussed ten years ago, as then many experts were enthusiastic enough to imagine that the combination of refuse destructors with electric generating stations would revolutionise the business of electricity supply. At that time Professor Forbes stated that in most towns there was just sufficient refuse to provide 8 c.p. of light per head of population, but another well-known expert promised to provide all the power required as well as light. Mr. Tomlinson's dictum was that you must burn the refuse inoffensively first, and afterwards produce as much steam as possible.

Mr. N. HOSGOOD (Assistant Engineer, Pembroke) also spoke commenting on the insanitary methods of refuse collection usually employed.

A New Paper Shade.—We have received from the "Sylverlyte" Shade and Reflector Co. (4 Milk Street, E.C.) a sample of a new cardboard conical shade, in which the interior surface is roughened and coated with a reflecting metallic paint.

It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.

SUMMARY

A 16-c.p. Osram lamp for pressures between 100 and 130 volts, and a 32-c.p. lamp for pressures up to 260 volts, have been put on the market by the General Electric Co., of London. The former consumes 17 watts, and the latter 40 watts. We are able to publish some tests made on nine 222-volt 50-c.p. Osram lamps at the National Physical Laboratory for the General Electric Co. which show that the lamps were remarkably uniform in their behaviour. Five of the lamps lasted over 2,000 hours. The figures show that the average candle-power at the end of that period was 87 per cent. of the initial value, and the watts per candle averaged 1·45 over the 2,000 hours. The average watts per c.p. during the first 1,000 hours were well below 1·3, and at the end of 1,000 hours the candle-power was higher than at the start. (Page 501.)

The Phœnix Fire Office has issued a new edition of its wiring rules, which is reviewed in an article on Page 502.

The application of steam turbines to the utilisation of exhaust steam, either from condensing or non-condensing engines, is discussed in an article which also contains illustrations of machinery of this class manufactured by Messrs. Willans & Robinson. (Page 503.)

Descriptions are given of the latest form of a well-known make of electric fans, a new self-contained petrol-driven electric lighting set, and a line of continuous-current machines which has been recently introduced. (Pages 504 and 505.)

A large octuple rotary press, electrically-driven and controlled on the Crompton-Kohler system of multiple push-button control, has recently been installed in the printing office of *The Times*. The press can be controlled from sixteen different points, and a very gradual start and a wide range of speed is obtained. A small motor is used for the lowest speeds, the load being transferred to a large motor when a certain speed has been attained. (Page 506.)

The annual report of Mr. G. S. Ram, Electrical Inspector of Factories and Workshops to the Home Office, comments on certain dangerous conditions often met

Digitized by Google

with, both in public supply stations and factories, and indicates means by which some of these could be avoided. He particularly urges the necessity for a better design of plugs and sockets, and emphasises the necessity for more efficient earthing of motor frames, &c. Fourteen fatal and 312 non-fatal accidents were reported, many of which Mr. Ram considers were of a preventable nature. He makes a few comments on the exhibits at the recent Manchester Exhibition, many of which indicate, in his opinion, that greater attention is now being paid to the question of the safety of the worker. (Page 507.)

FOUR young English telephone engineers, accused a year ago of stealing documents and trade secrets from the Bell Telephone Co., of Antwerp, on leaving to take up an engagement with the General Electric Co. in this country, were placed on trial on Thursday. (Page 509.)

THE accounts of the Brighton Corporation electricity department for the year to March 31st, show a profit of £564, against a loss of £3,657 in the previous year.—There was a profit of £2,222 upon the Carlisle electricity undertaking last year.—The Local Government Board have refused to sanction a loan to the Gravesend Corporation unless the system of account keeping is entirely rearranged.—The receipts upon the Sunderland Corporation tramways department for the past year are the lowest since 1903. The revenue of the electricity department decreased by £10,000 during the same period. (Page 509.)

A 200-kw. alternator is required by the Barking Council. The West Ham Corporation are to seek a loan of £5,000; and the Dundalk Council a loan of £25,000. L.G.B. inquiries have been held at Hereford (£8,000) and Worthing (£3,900). Electrical stores are required at Devonport; a 100-h.p. motor at Leeds; and a traction battery and automatic booster at Dudley. (Page 511.)

THE Norwegian Nitrate Works, Ltd., the owners of the Birkeland-Eyde patents, are working in conjunction with the Badische Anilin- und Sodafabrik and its allied companies in connection with the electrical manufacture of nitrates for fertilising purposes, and some large works are being constructed in Norway for this purpose. Experiments are now progressing to determine the most efficient form of arc furnace. The furnace developed by the German company consists of a long metal tube, the arc being blown down the centre by a spiral current of air; in that of the Norwegian company, the arc is blown out into a disc by the action of a strong magnetic field. We describe the former furnace in some detail. Mr. Eyde gave a full description of the other furnace and the process of manufacture in a Paper before the Royal Society of Arts last Wednesday. (Page 515.)

WE are able to publish the results of comparative tests of the experimental gas and flame arc street lighting, which has been put down in a street in Bradford. These show that although the distribution of light is not so uniform with the arc lamps as with the gas lamps, owing to the latter being placed close together, the average and the maximum illumination was much greater in the case of the electric lighting, notwithstanding the fact that the cost of the electric lighting works out at 6s. 5d. per yard, as against 7s. 5¾d. per yard for gas (taking gas at 2s. 1d. per thousand cu. ft., less 12½ per cent.). Owing to reasons, however, which are not immediately apparent, gas lighting has been chosen. (Page 517.)

AMONG the specifications published by the Patent Office on Thursday last is one by the Westinghouse Metal Filament Lamp Co. for a process of making tungsten filaments without using any binding agent to make the tungsten powder into a paste. F. Wilkins has a specification describing a lamp cap for incandescent lamps, provided with a hood which prevents the access of water to the holder. The use of tetrachloride of carbon instead of oil in the tanks of H.T. switches is patented by A. E. Peyrusson; and the British Thomson-Houston Co. have protected a new form of support for metal filaments. The filament passes through a small tungsten loop held by a springy, nickel wire, which is itself welded to a copper support. A new method of producing a ductile nickel-tungsten mixture for drawing into filaments is described in another specification by Siemens & Halske Akt.-Ges. A patent taken out in 1898 by B. G. Lamme for the regulation of the D.C. voltage of rotary converters by means of tappings on the transformer has been dropped. (Page 519.)

THERE are signs of greatly increased activity amongst the various manufacturers of metal filament lamps. In spite of the fact that when the lamps were first introduced several experts expressed the opinion that it would be next to impossible to produce a tungsten filament giving a comparatively low candle-power at a high voltage, this is already being accomplished. As mentioned elsewhere in this issue, the General Electric Co. have now placed a 16-c.p. 100- to 130-volt Osram lamp on the British market, and a 32-c.p. lamp of the same make for pressures up to 260 volts can now be obtained. That this does not yet represent the limit is shown by the fact that the Allgemeine Elektricitats Gesellschaft, of Berlin, are already advertising in the German papers a 25-c.p. 200- to 250-volt tungsten lamp, and we understand that the Sunbeam Lamp Co., of Gateshead, will be in a position to deliver 22-c.p. tungsten lamps for pressures up to 250 volts in the course of a few weeks. This movement is very different from one which has always characterised the carbon filament lamp market, namely, that irresponsible agents have pushed the sale of cheap lamps rated for high initial efficiency and short useful life among the more ignorant classes of lamp buyers. Experience has shown that such lamps as the Osram fulfil far more than the public has demanded from them and than the makers and sellers have claimed. The long life and constancy of candle-power and efficiency is well demonstrated by the results of the tests made on some 50-c.p. 220-volt Osram lamps by the National Physical Laboratory, which we publish in this issue; and there is no reason to doubt that the Osram lamps of lower candle-power, more adapted to the use of the average consumer, will be of an equally high quality. As to the prices of the new lamps, the keen competition ensures that these will be kept down to the lowest practicable values. One effect of the arrival of the new low candle-power tungsten lamps is already to be seen in the reduction in the price of tantalum lamps, which we also announce in this issue.

Telegraph Traffic.—Censorship has been established on telegrams to and from Monte Christy, Republic of Domenica, the result, no doubt, of some local insurrection, as telegrams for other towns are not apparently affected.—The line between Bagdad and Bassorah was down for a short time on 31st ulto.—Telegrams for Ecuador, excepting those destined for Guayaquil and St. Helena, are only accepted at sender's risk, and this also applies to the Isthmus of Panama, with exception of the towns of Colon and Panama.—Sender's risk and Censorship also rules on telegrams to Costa Rica, Nicaragua, and Honduras. In fact, it appears hardly likely that the Central American Republics will be able to permit free telegraphic intercourse for some considerable time.

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, JUNE 3RD.

Royal Institution.

3 p.m. Afternoon Lecture I., by Prof. W. E. Dalby, on "A Modern Railway Problem: Steam *v.* Electricity."

Röntgen Society.

8.15 p.m. Annual General Meeting at 20 Hanover Square, London, W. Mr. R. S. Wright will show and explain the new "Snook" Röntgen apparatus.

FRIDAY, JUNE 4TH.

Royal Institution.

9 p.m. Evening discourse by Prof. J. A. Fleming, F.R.S., on "Researches in Radiotelegraphy."

MONDAY, JUNE 7TH.

East London College.

8 p.m. Special Lecture on "The Technical Aspect of the G.B. System of Electric Tramways," by Prof. J. T. Morris. Mr. W. H. Patchell will preside.

THURSDAY, JUNE 10TH.

Royal Institution.

3 p.m. Afternoon Lecture II., by Prof. W. E. Dalby, on "A Modern Railway Problem: Steam *v.* Electricity."

FRIDAY, JUNE 11TH.

Physical Society.

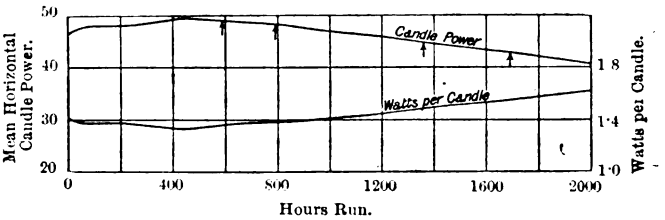
8 p.m. Meeting at the Imperial College of Science, South Kensington. Among the Papers down for reading are the following:—(1) "The Arthur Wright Electrical Device for Evaluating Formulæ and Solving Equations," by Dr. A. Russell and A. Wright; (2) "The Proposed International Unit of Candle Power," by C. C. Paterson; (3) "Inductance and Resistance in Telephone and other Circuits," by J. W. Nicholson; (4) "Note on Terrestrial Magnetism," by G. W. Walker.

Royal Institution.

9 p.m. Evening Discourse on "Problems of Helium and Radium," by Prof. Sir James Dewar, F.R.S.

OSRAM LAMPS

A 16-c.p. 100-Volt Lamp
Life Tests on 220-Volt Lamps



THE 16 candle-power Osram lamp for pressures between 100 and 130 volts has now appeared on the British market in company with a 32 candle-power lamp for pressures between 200 and 260 volts. The General Electric Company inform us that they are now prepared to deliver these lamps in any quantities. The price of the 16-c.p. 100/130-volt lamp is 2s. 9d., and that of the 32-c.p. 200/260-volt lamp, 4s. 3d.; the prices of the other sizes of Osram lamps, including the high candle-power lamps, will be found in our advertisement columns.

The new 16-c.p. lamp takes 17 watts and gives 16 Hefner candles (14·4 British c.p., taking the conversion factor as 0·9), and the efficiency is 1·06 watts per Hefner candle, or 1·18 per British candle. It is made in two patterns: in a spherical globe with an overall length of 4½ inches, and in the normal "Osram" shape with an overall length of 5¼ inches. The filament is, of course, finer and shorter than that of the larger lamps, but otherwise it is the same filament, and the separate loops are supported in the usual manner by platinum-iridium wires with hooks, which keep them in tension. We are informed that the small diameter of the filament renders it more elastic than the filaments of larger candle-power lamps, with the result that there are even fewer breakages with the new lamps. The life of the lamps is said to average about 2,000 hours, as in the case of the other Osram lamps, and they are all suitable for series running and burning at an angle.

The 32-c.p. lamp takes 40 watts, and reckoning the British candle-power at 28·8 c.p., the efficiency is 1·39 watts per candle. No life tests have as yet been carried out on this lamp, but there is every reason to believe that it will attain to the average of 2,000 hours. The overall length of this lamp is 5½ inches.

In the meantime, thorough tests of the older patterns of 220-volt Osram lamps show extremely good results. The following are the results of tests made at the National Physical Laboratory for the General Electric Company on nine 222-volt 50-c.p. Osram lamps which, we are informed, were not selected, but taken from stock. Before the life tests were commenced an initial test showed that the mean horizontal (British) candle powers varied between 43·6 and 48·2, the average being 46·6. The watts consumed averaged at 65, and the watts per candle 1·4. The lamps were then tested in a pendant position at a constant pressure of 222 volts, and readings taken at intervals over a period of 2,000 hours, at the end of which time five of the lamps were still burning. On the occasion of a filament breaking no attempt was made to re-fuse the limbs together; and if fusion occurred automatically, the lamp was counted as having broken. The points where the four lamps broke down are marked by arrows in the accompanying curves, which show the average results for the nine lamps.

It will be seen that the candle power increased initially until a maximum was reached after about 400 hours. Subsequently a slow decline took place, the initial value being reached again after 1,100 hours. The average watts per candle are also plotted. Curves of the performance of the individual lamps accompany the report, and these show that the behaviour of the lamps was strikingly uniform. All the lamps reached a maximum candle power (which varied between 47·5 and 50·5 c.p.) shortly after 400 hours, and the candle powers of the five remaining lamps at the end of the 2,000 hours' run were within the limits of 39 and 42 c.p. The average candle power throughout the life of 2,000 hours of lamps burning at any time was 46·2 c.p., and the average watts per candle over the same period 1·45. The four breakages occurred at 600, 800, 1,350, and 1,700 hours respectively. The curve for average candle power shows that after 1,000 hours the candle power was higher than the initial figure, and that after 2,000 hours it had fallen to 87 per cent. of its initial value. The other curve shows that the consumption was lower than the rated figure of 1·4 watts per candle for the first 950 hours, falling as low as 1·33. At the end of the 2,000-hour test it had risen to only somewhat over 1·6 watts per candle.

AVERAGE CURVES OF LIFE TEST ON NINE 222-VOLT 50-C.P. OSRAM LAMPS.

Managers' Section of Municipal Tramways Association.—A meeting of the Managers' Section of the Municipal Tramways Association was held at the Newcastle Town Hall on Thursday, under the chairmanship of Mr. A. L. C. Fell. Sir Joseph Ellis, chairman of the Newcastle Corporation Tramways Committee, welcomed the visitors. A number of Papers were discussed in private.

Examinations in Wireless Telegraphy.—We have received from Dr. Walmsley, principal of the Northampton Polytechnic Institute, London, a copy of the first examination paper set on the subject of wireless telegraphy. The examination was held last month on the conclusion of a course of lectures delivered at the Institute by Dr. J. Erskine Murray. Of the students who attended the course, 83 per cent. took the examination, and the average marks obtained were 68 per cent. The questions included some general ones on the generation and transmission of electric waves, and others on aerials for directive transmission and on detectors. The different methods of coupling oscillatory circuits, and the measurements made in wireless work were also referred to.

THE NEW PHŒNIX FIRE OFFICE WIRING RULES

MR. S. G. CASTLE RUSSELL, Electrical Adviser to the Phœnix Fire Office, has sent us an advance copy of the thirty-eighth edition of the Phœnix Fire Office Rules for electric light and power installations, &c. The most noticeable alteration is the reduction in their length, a large amount of repetition and redundant matter having been omitted. The last edition of the rules occupied 60 pages, and the present edition fills only 38. Another alteration noticeable is that the expression "to the approval of the technical adviser of the Fire Office" is not made use of quite so frequently, and an endeavour has been made to explain the precise requirements of the Fire Office more definitely in the rules themselves. The word "approved" is, however, retained here and there. For instance, "switch lamp-holders must be of approved type," and "lamp-holders and caps must be of approved design and construction." With regard to the key holders, this is nevertheless an advance over the previous regulations, as hitherto it was specified that switches contained in lamp holders would only be allowed "in those places and under those circumstances for which permission has been obtained from the technical adviser of the Fire Office," a regulation which we think must have been very frequently disregarded.

The introductory note to the regulations has been retained. In this the opinion of the Phœnix Fire Office is expressed that electric light is the safest of all illuminants and preferable to any other, and is at the same time accompanied by a warning that "any firm by arranging to place inferior quality of work in your premises can easily underprice other firms who are more conscientious." A new paragraph at the foot of this introduction strongly recommends the retention of advising engineers to design and supervise the erection of installations, to conduce to both safety and economy.

In the rule as to conductors, a sectional area at the 1,000 ampere per sq. in. rating is still specified. All conductors of larger sectional area than 16 S.W.G. must be stranded, and no conductor is to have a smaller section than 18 S.W.G. except in fittings; in fittings No. 20 or 3/22 is to be the smallest size.

Wood casing and open seam piping with socket connection is only allowed for surface work. All buried wires must be in welded or solid-drawn iron or steel pipes "or other approved fireproof and water-tight bushed pipes."

All the rules do not contain the word "must." For instance, "all joints in piping should be treated with aluminium paint. . . . The use of tee-pieces and elbows is not recommended; plain junction boxes should be used throughout."

Lead-covered wiring is now officially recognised by the Phœnix office; it must be earthed, and for A.C. work the two wires must be in the same lead tube or covering.

In the matter of earthing there is a rule which must obviously be frequently disregarded if earthing is to be done at all efficiently; this is that "the connection of the earth wire to gas piping and hydraulic mains is strictly prohibited." There are electricity supply undertakings which do not allow wiring contractors to earth on to the sheathing of their cables, and in such cases where a lead-covered system or an iron-barrel system of wiring is employed, it is far safer to earth to the water main than to leave it to the wiring contractor to improvise an earth.

Unprotected wiring is now allowed when the consent of the Fire Office has been obtained. The conductors are then to be wired on insulators, or with porcelain or earthenware cleats. They "should have a clearance of 4 in. apart horizontally, and no conductors should be less than 4 in. free from any conducting material, unless special precautions have been taken against contact. . . . In no case should the supports for any conductor be so far apart that, if the conductor broke close to the insulator, either end could reach the floor or ground below." Surface systems of flexible twin wiring are allowed where the wires will not be liable to mechanical injury or damp, chemical action, &c., if the system method of fixing, &c., and the insulation and protective covering are carried out to the approval of the Fire Office

Among the rules for flexible wires, there is one to the effect that flexible cords "must not be joined to hard wiring except by means of screw connections in a fireproof junction box." Flexibles are to be insulated with two laps of pure rubber, each 10 mils thick. There is to be a lap of cotton next to the rubber, and two laps of cotton between the rubber and the external braiding. The insulation must not be less than 1,000 megohms per mile "dry test." Vulcanising rubber insulation is also permitted for flexibles. It is to have an insulation of 600 megohms per mile of 24 hours' immersion in water. There is to be a layer of pure rubber between the copper and vulcanising rubber It is to be noted that the term "vulcanising rubber" is specifically used, so presumably the Phœnix Office is satisfied in this case with compound rubber which has not been actually vulcanised. Flexible cords used in shop windows containing inflammable goods must have an efficient flame-proof outer covering. Flexible cords "should" not be used for wiring the interior of electroliers.

Arc lamps are not allowed in cotton mills and similar "hazardous" risks unless they are of the double enclosed type, or are inverted arcs. In the latter case instructions are given for the amount which the lower reflector must project beyond the arc.

In the case of floor and wall sockets, unless combination switch and wall sockets are used, the groups of wall sockets in each lamp must be controlled by a switch.

The rule as to distributing boards, if interpreted literally, implies that in the case of iron or steel barrel systems, a cast-iron case with glazed front should be used. We do not think that this can be intended, and as the word "should" is employed, contractors would be quite safe in employing the ordinary distributing boards with hard wood cases when they desire it.

The Phœnix rule for fuses "more honoured in the breach than in the observance" is still that a fuse must blow at 50 per cent. overload. The latest edition of the rules of the Institution of Electrical Engineers specifies 200 per cent. We believe that the majority of consulting engineers and contractors work to 100 per cent. in the case of house wiring.

The size of the circuits from the distributing boards is 5 amperes for 100, and 3 amperes for 200–250 volts as hitherto; but 25 volt and 50 volt systems are now recognised, in which cases the maximum currents permissible from each way are 8 amperes and 6 amperes respectively.

The rule for auto-transformers is as follows:—"Auto-transformers must be of sufficient capacity to stand an overload of 25 per cent. for short periods. Pressure of supply must not be transformed to a lower voltage unless the wiring is of the capacity required under these rules. The transformers must be totally enclosed in strong cast-iron cases with removable lids. Terminals to be within the iron case, and the leading-in holes for cables fitted with bushes, except when metal pipes are screwed direct into the case. The metal cases and frames of transformers must be earthed." The second sentence of this might be made a little clearer, for irresponsible wiremen might be inclined to reconnect 200 volt 1,000-amperes-per-square-inch wiring on to a 25 volt system, with the result that wires which had been working at the full current density at 200 volts would be working at 2,700 amperes per sq. in. at 25 volts, even after allowing for the reduced current consumption of the metal filament lamps.

The rules for motors have been entirely revised and abbreviated. Motors of the ventilated type are specified. The frames of the motors and metal case apparatus in connection with them must be earthed. This regulation will doubtless be much neglected on 100-volt and 200-volt work, and it also appears unnecessary in the case of the numerous small motors which take little or no more current than an ordinary portable lamp. It is also stated that each motor should be furnished with an "approved automatic no-voltage and overload release"; the word "should" is here used, and, of course, it is quite unnecessary in the case of such small motors as those referred to above. We should prefer, however, to see a rule that all motors above a certain horse-power "*must*" have a starting switch with no voltage and overload release, and the rules might very well contain a provision that these starting switches should be protected by covers. An ordinary switch has to have a cover, and yet contractors very frequently put in open type starting switches which introduce quite an unnecessary amount of danger in the installation. There should also be a definite rule that starting switches must not be used as regulating switches unless specially designed for the double purpose.

In the rules as to service wires, it is stated that the conductors should be carried in iron barrel, but we can see absolutely no objection to the very common practice of using ordinary armoured cable for service wires.

Rules are included with regard to telephone wires, specifying that the insulation of a telephone circuit inside a building should never drop below one megohm, and that a high-voltage fuse must be placed upon the telephone wire. Both of these regulations seem unnecessary in ordinary cases.

In the rules under the heading, "Electric Heating," it is only those in which the word "should" instead of "must" is used that will be disregarded. For instance, it is stated that all radiators should be fixed to, or stand upon, approved fireproof insulators, and that a wire guard should protect the radiator lamps. On the other hand, in the case of laundries and similar places, the precaution of earthing electrically heated flat irons is called for and is reasonable, although this means utilising a three-wire flexible.

The insulation resistance now specified for lighting installations is 40 megohms, divided by the number of points, which is double that in the previous edition of the rules, and nearly double that of the Institution of Electrical Engineers rules.

A short rule has been added relating to temporary installations.

In this article we have only reviewed some of the leading features and points of novelty of the new Phœnix rules; the whole book will repay careful perusal by wiring contractors and consulting engineers.

VACUUM TURBINES

MESSRS. WILLANS & ROBINSON (Rugby) have given a good deal of attention to the construction of "Vacuum" turbines for working in conjunction with reciprocating engines, and we are able to give a few illustrations of actual machines now working in this way. It is perhaps not always realised that although the greatest savings are to be achieved with vacuum turbines where the existing engines are working non-condensing, in as much as the whole of the exhaust steam can then be utilised in the turbine to produce additional power without calling upon the boilers to generate more steam than previously, yet savings worthy of serious consideration can also be made where the existing engines are working condensing, by the introduction of a vacuum turbine between the engines and the existing condensing plant. Indeed, it may almost be said that there is a larger field for the vacuum turbine in condensing stations than in non-condensing stations, because in a non-condensing station the lack of cooling water for condensing may present too many difficulties to justify a vacuum turbine with its attendant condenser being added. On the other hand, whilst the cost of installing condensing plant in connection with reciprocating engines might not be justified, the adoption of condensing plant may easily be justified with a combination of reciprocating engines exhausting into a vacuum turbine.

As the introduction of a vacuum turbine into a non-condensing station necessitates a supply of cooling water for the condensing plant, this is the first point requiring attention. Where the lack of cooling water has been the cause of previously running non-condensing, it will no doubt be found, owing to the peculiar capacity which a turbine possesses for "utilising a vacuum" to its uttermost extent, that the saving in steam consumption in a combined reciprocating engine and turbine set is so great that the cost of cooling towers or ponds is often justified in order to introduce condensing plant and to make possible the adoption of a "vacuum" turbine.

It should also be borne in mind that, whereas when running non-condensing the exhaust steam is lost (excepting that portion —if any—which is used for heating the boiler feed water), this exhaust steam would now be saved if a surface condensing plant is installed. Further, that with a surface condensing plant of the vacuum augmenter type, the temperature of the air-pump discharge is approximately the temperature corresponding to the vacuum, thus enabling the condensed steam to be passed into the boilers through an economiser without previously heating it.

Since the Willans-Vacuum Turbine is primarily designed for receiving steam at about atmospheric pressure, and non-condensing engines discharge their steam at this pressure, the

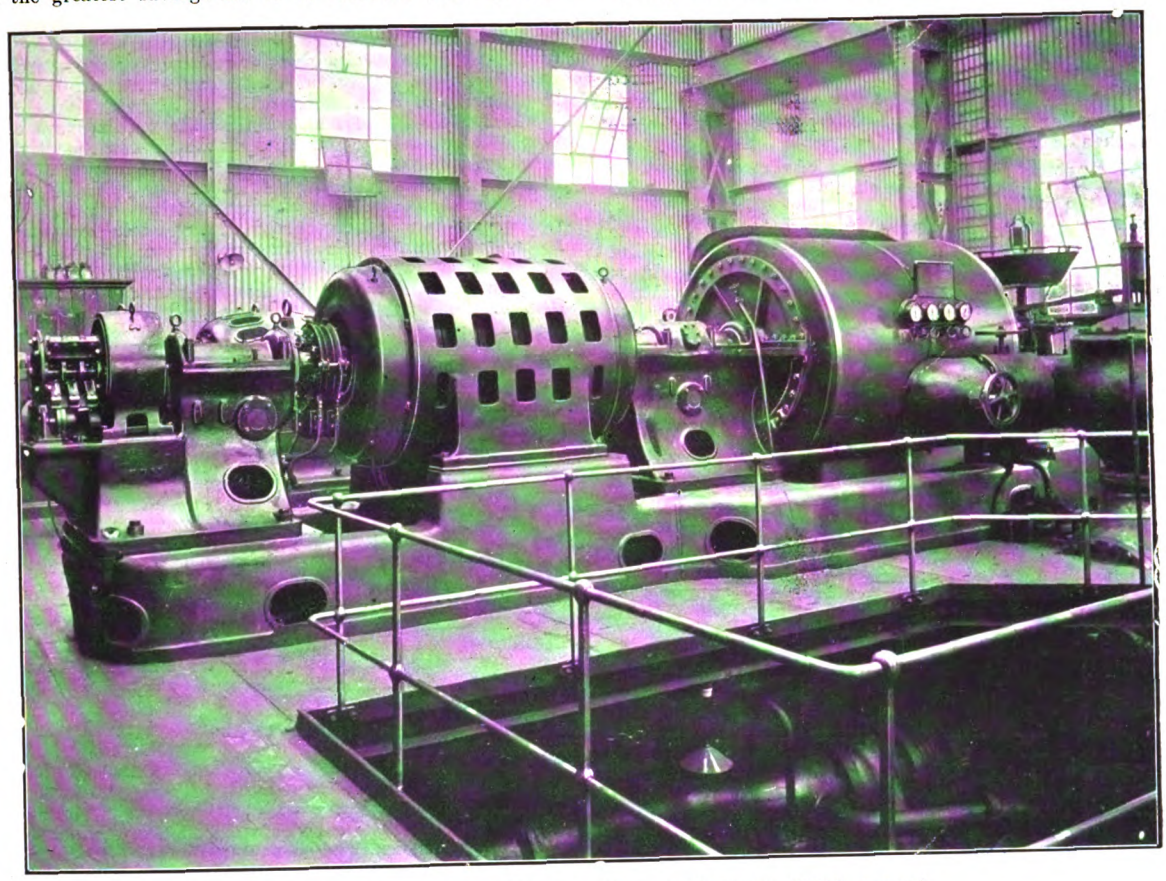

FIG. 1.—WILLANS-PARSONS 1,350 KW. VACUUM TURBINE (2,400 R.P.M.).

FIG. 2.—ROTOR OF 1,350 KW. WILLANS VACUUM TURBINE, RUNNING AT 2,400 R.P.M.

E

Digitized by Google

engines will develop the same power whether discharging their steam to the atmosphere or into the turbine, without any alteration to their valve-gear or cylinders. Further, the same output will be obtained from the reciprocating engine without using more steam than previously, and the power which the turbine can produce from this steam is a net gain less the small amount of power required for driving the condensing plant. As an example of the power obtainable from the exhaust steam from reciprocating engines, it may be said that in the case of a 500 kw. engine running compound non-condensing with steam at the stop valve at a pressure of 160 lbs. per sq. in. and superheated by 100° F., a vacuum turbine can render available an extra 320 kw. less 5 per cent. of 320 kw. required for driving the condensing plant, or 304 kw. net.

Scarcity of cooling water is not a usual feature in condensing stations, but should such be the case the addition of cooling towers or ponds to supplement the exsting supply of water would often be fully justified. When contemplating installing a turbine for working with the exhaust steam from reciprocating engines, already condensing, the following points arise :—(1) Can the output of the existing engines be maintained when exhausting into the turbine instead of into the condenser? (2) If it is impossible for the existing engines to maintain their output under the altered conditions, to what extent will their output be reduced, and to what extent will this loss be counter-balanced by the output obtained from the turbine set? (3) Is the existing condensing plant of sufficient capacity to deal with the steam and maintain a sufficiently good vacuum for purposes of the turbine? If not, what means can be adopted for improving the vacuum without installing new condensing plant?

The introduction of a turbine between an existing engine and condenser necessitates the raising of the pressure in the exhaust chamber of the engine, and if the previous output of the engine is to be maintained this can only be done by an alteration to the valves or cylinders of the engine, and at the expenditure of a larger quantity of steam than previously. In many cases no difficulty will be found in supplying more steam to the engine than before, and as shown below this additional steam will produce power at an extremely economical rate, and consequently the introduction of a turbine not only increases the combined output of the plant, but appreciably improves the steam consumption of the plant. Taking as an example a 500 kw. triple expansion engine using steam at a pressure of 160 lbs. per sq. in., superheated by 100° F., and exhausting into a 25 in. vacuum, the introduction of a turbine will necessitate this engine exhausting at a pressure of, say, 16 lbs. absolute. The output of the engine will remain the same as before, but it will require about 30 per cent. more steam, and assuming an average case where the engine was using 9,500 lbs. of steam per hour (19 lbs. per kw. hour) when condensing, it will now be using 12,350 lbs. of steam per hour, but the output of the plant will be increased from 500 kw. to 800 kw.

That is to say, the additional 300 kw. is produced at a cost of 2,850 lbs. of steam, or for 9·5 lbs. of steam per kw. hour. Thus the over-all efficiency of the plant has been improved from 19 lbs. of steam per kw. hour to 15·44 lbs. of steam per kw. hour.

Even in those cases where it is impossible to maintain the same output from the engine when exhausting into a turbine instead of into a condenser, savings may be expected by installing a vacuum turbine. Taking the same 500 kw. engine as above, but with no alterations to valves, &c., the output of the engine can be assumed to fall to 380 kw., and whilst the engine was previously using 9,500 lbs. of steam per hour it will now be using at 380 kw. about 10,050 lbs. per hour. This quantity of exhaust steam enables the turbine to produce about 240 kw. Here an additional 120 kw. has been produced for an expenditure of 550 lbs. of steam, or at the rate of 4·58 lbs. of steam per kw. hour, and the over-all efficiency of the plant has been improved from 19 lbs. of steam per kw. hour to 16·2 lbs. of steam per kw. hour.

These two examples asume that the turbines are exhausting into a vacuum of about 27·5 in., and consequently that the existing condensers are capable of maintaining a vacuum of 27·5 in., and the question naturally arises whether the existing condensers are capable of this, and, if not, what alterations are necessary. It will be gathered that the total quantity of steam to be dealt with is increased in each case, and therefore where a separate condenser is fixed to each engine the vacuum under the new conditions will be less than under the previous conditions. This would result in the estimated output from the turbine falling short of that laid down above—unless alterations could be made to raise the vacuum to 27·5 in. Where one central condensing plant serves two or more engines, it is possible that the introduction of a turbine will enable one engine to be shut down altogether, in which case the load on the condensing plant will be reduced, and it will probably be found capable of maintaining the desired vacuum without any alteration. In case, however, the condensing plant is not able to maintain a sufficiently good vacuum for the turbine, the desired results will usually be attained either by increasing the quantity of cooling water, or fitting a vacuum augmentor. Although the above remarks have been confined to surface condensing plants, Messrs. Willans and Robinson point out that their turbine is equally capable of working with jet condensers.

The foregoing deals only with the salient points arising when the installation of a vacuum turbine is contemplated, but the following additional points might with advantage be borne in mind :—Where an existing engine is at present being worked continuously beyond its normal full load capacity, this overload may be transferred from the engine to a turbine arranged for working with the exhaust steam from the engine. Where the engines are no longer able to give their normal full load output, due to a reduction in the boiler pressure, the installation of a vacuum turbine will make up for the deficiency in question. A vacuum turbine installed for working in conjunction with a reciprocating engine can be supplied with high-pressure steam in the event of the reciprocating engine being out of commission. In the event of the turbine being out of commission, the engine would exhaust, as previously, into the condenser. In Fig. 1 is shown a 1,350 kw. Willans-Vacuum Turbine which is one of two sets installed at the works of Sir Bernard Samuelson & Co., Middlesbrough-on-Tees, and Fig. 2 shows the construction of the rotor of this class of machine.

STURTEVANT PROPELLER FANS

THE Sturtevant Engineering Co., Ltd. (147 Queen Victoria Street), have given us some particulars of their latest patterns of electric propeller fans. A continuous-current Sturtevant fan is illustrated complete in Fig. 1, while Fig. 2 gives an idea of the construction of the motor employed by showing the various parts dismantled. Fans of the propeller type are designed for use where resistances are slight and velocities low. For forcing or drawing air through extensive systems of piping,

FIG. 1.—STURTEVANT CONTINUOUS-CURRENT FAN.

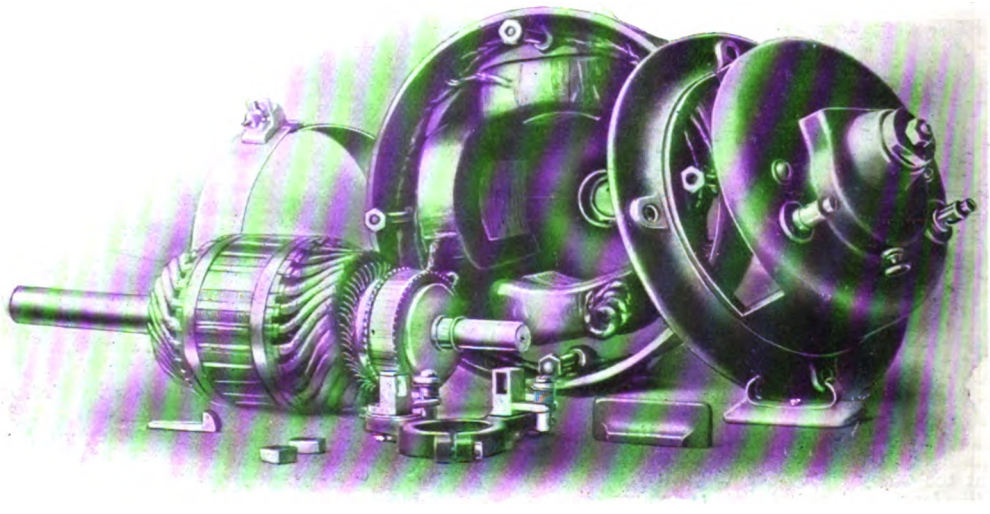

FIG. 2.—FAN MOTOR DISMANTLED.

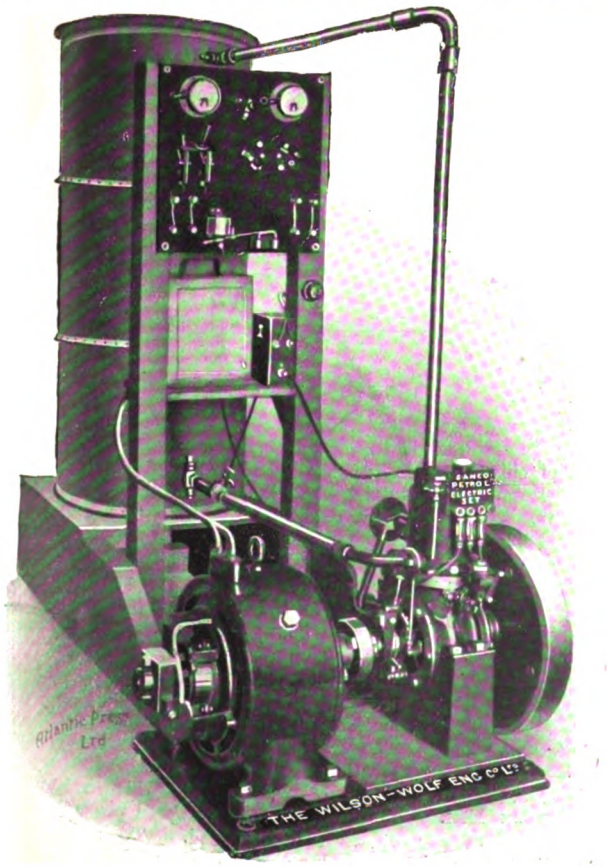

Digitized by Google

for the production of mechanical draught for boilers, or for conveying material, centrifugal fans of the cased type are necessary, but where it is required to move large volumes of air against low resistances, propeller fans are both efficient and low in first cost. The results obtained from exhaustive experiments with various types of blades have induced the firm to adopt the open or propeller type in preference to the so-called "box-blade" on account of the superior efficiency of the former, and the ease with which the angle of pitch can be adjusted to suit various conditions. The fan-wheel is keyed direct on to the motor-shaft, so that only two bearings are required. The fan-wheel itself consists of six blades, shaped to prevent the possibility of reverse air-currents, and to give the maximum air displacement in an axial direction with a minimum of friction and noise. The blades are of sheet steel riveted to substantial wrought-iron arms, which are screwed into the cast-iron hub and held in place by locknuts. With this arrangement the blades may be set at any desired angle, but are always adjusted to standard gauge before leaving the works.

The motors which have been specially designed for this particular work are of the totally enclosed and dust proof multipolar type. The body consists of a cast-iron shell which is bored out to receive the field stampings, the back part of the shell forming one end cover and containing one bearing. The front end cover is a separate casting, and is fixed in place by bolts extending right through the laminated yoke. It is fitted with an adjustable thrust-block, which takes up the thrust of the fan with a minimum of friction. The cover is further provided with a polished brass or planished sheet steel enclosing band, secured by a milled head nut and easily detachable. On removing this band the brush-gear and commutator are easily accessible. A special feature of these motors is that all sizes from 12 in. upwards are fitted with ring oiler bearings. When the fan is intended for running with vertical spindle, the bearings are solid, and provided with grease lubrication by means of self-feeding Stauffer lubricators.

SMALL PETROL-DRIVEN ELECTRIC-LIGHTING SETS

THE accompanying illustration represents a complete petrol-driven electric lighting outfit which has been brought out by the Wilson Wolf Engineering Co., Ltd. (Thornton Road, Bradford), under the name of the "Sanco" petrol-electric set for country-house lighting and similar purposes. The engine which drives the dynamo is a single-cylinder petrol engine, with a two-stroke cycle with a patent scavenging valve which is claimed to make back-firing impossible, and to give great economy in fuel consumption. There are no valves exposed to the extreme temperature of the burning gases, the ingress of the explosive mixture and egress of the products of combustion being controlled by the piston covering and uncovering two ports in the cylinder. The method of operation of the scavenging device is as follows:—An intermediate chamber is provided between the crank-case and cylinder, and at each revolution of the engine this chamber is filled with pure air, which enters the cylinder under pressure immediately after each explosion, and effectually sweeps out the burnt gases before the new charge of explosive mixture enters. The whole outfit is supplied complete with switchboard and a special wooden stand ready for piecing together, so that the labour and cost of erection is very small. The sets are made in four sizes, from 50 to 130 lights, and are designed for use with 25-volt 16-c.p. metal filament lamps, and for 50-volt lamps. The 50-light set requires one-third of a gallon of petrol per hour. A 14-cell or 28-cell battery is used in conjunction with the sets, according as they are for 25 or 50 volts.

PETROL-DRIVEN ELECTRIC LIGHTING OUTFIT.

SOME NEW CONTINUOUS-CURRENT MACHINES

THE British Thomson-Houston Co. (Rugby) have sent us particulars of an entirely new design of continuous current machines, both motors and dynamos, known as the DH type, which embody some interesting features. The construction of the armature in this type calls for no particular attention, except that, at the ends of the core and also in each ventilating duct, steel spacers are provided to support each tooth. This prevents the vibration which may occur with unsupported teeth. The winding consists of former wound coils. The magnet frame is of cast iron, but the main poles are built up of laminated steel, and can be removed with the field spools, without displacement of the armature. The bearings are carried either in end shields, bolted to the frame, or in pedestals. In the former case, the end shields and bearings can be turned through 90° or 180°, thus allowing the motor to be mounted on the floor, wall, or ceiling. The carbon brushes are carried in brush holders of the clock spring type.

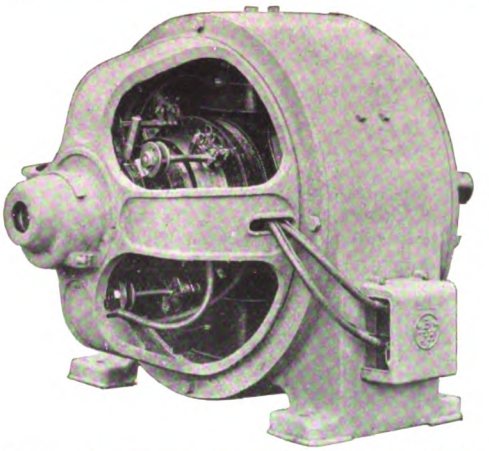

FIG. 1.—PROTECTED MOTOR (COMMUTATOR END).

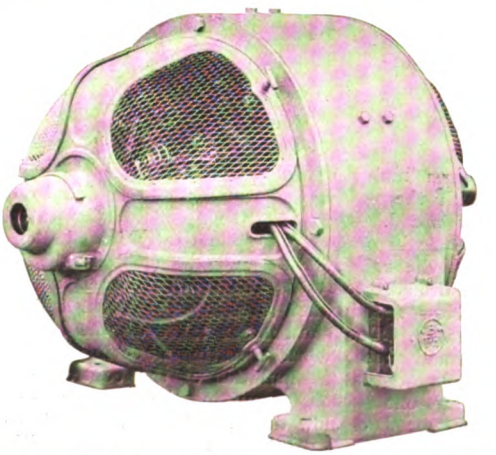

FIG. 2.—MOTOR WITH EXPANDED METAL COVERS.

The accompanying illustrations show two motors of this type. All machines will stand full load for six hours with a temperature rise (by thermometer) not exceeding 40° C. (72° F.), and will stand 25 per cent. overload for one hour and 50 per

Digitized by Google

cent. momentarily. They can be obtained with expanded metal covers, or perforated metal covers. In the latter case, with ½ in. diameter holes, the temperature rise on any standard rating will not exceed 45° C. (81° F.). With totally enclosing covers, the ratings are special. Solid covers provided with holes at the bottom of the commutator and pulley end shields can be obtained, and in this case the armature is equipped with a fan which circulates the air inside the motor, drawing in the cool air at the commutator end. These latter machines are rainproof. If required to be dustproof, a pipe can be led from a source where clean air can be obtained. Machines fitted with these covers will have a temperature rise not exceeding 40° C. (72° F.) for any standard rating, and are particularly suited for tool-driving where small chips of metal are liable to drop into the motor; for services in exposed positions; for paint-mixing machines, pumps, &c.; and for wood-working machines, coal hoists, &c., where falling dust is likely to enter the motor. Ratings of machines with flame-proof covers are special. Machines without commutating poles may be increased in speed 10 per cent. from normal by variation of excitation without causing excessive sparking, but when the required speed variation exceeds this, commutating poles will be required. The list describing this new line of machines gives very full particulars as to dimension and weight, and a complete list of all the different outputs, pressures, and speeds for which they can be obtained.

THE ELECTRICALLY-DRIVEN ROTARY PRESSES AT "THE TIMES" PRINTING OFFICE

A LARGE octuple press, electrically-driven and controlled on the Crompton-Kohler system, has recently been installed at the printing office of *The Times*, and was used for the first time on May 24th, when it printed the "Empire Day" edition. This press is the first of four machines of the same pattern which are to be installed. Each will be a double machine, capable of printing 60,000 copies of *The Times* per hour, and if required, the two units of each press can be worked separately. The system of control is the well-known "Kohler" system, developed by Messrs. Kohler Bros., of 56 Ludgate Hill, E.C., and the motors are by Messrs. Crompton and Co., Ltd., London and Chelmsford.

The equipment consists of two 60 h.p. and two 10 h.p. motors for each press, and the standard "Kohler" four-motor controller with sixteen push-button control stations at various points about the press, each station comprising a small iron box with five push buttons. The main 60 h.p. motor is coupled direct to an extension of the press shaft as shown in Fig. 1, which represents one of the two-motor sets of the first *Times* press. A worm-wheel runs free on the main shaft, but carries a ratchet-wheel, which engages with pawls pivotted on a disc keyed to the press shaft. The rotation of the worm by the

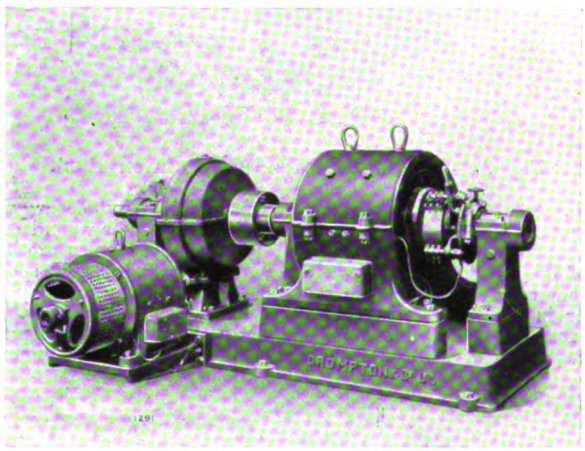

FIG. 1.—ONE OF THE TWO-MOTOR SETS FOR THE "TIMES" PRESS.

small 10 h.p. motor starts the worm-wheel and engages the ratchet with the pawls, and causes the machine to be driven at a slow speed. When the small motor has attained full speed, the main motor is automatically put in circuit, the pawls leave the ratchet free, and the small motor and worm-wheel are brought to rest. The small motor is used for operating at slow speed when dressing the press and leading in the paper web. The main motor takes up the load and over-runs the small motor when operating at printing speed.

The whole of the manipulation of the controller is carried out from any one station, permitting the operator to start, stop, run up the speed, or slow down, and also to lock the controller at any given speed or to lock it at the stop position. Thus absolute control of the movements of the press is placed in the hands of the operator from the point where he is working. For example, when putting on fresh plates, &c., the operator can make his adjustments and move the press just exactly to the point required without leaving his position, and when in that position he can lock the control so that the press cannot be moved until he has completed his task. This printing press can be used either as a whole to produce papers of 24 to 32 pages, or as two separate presses producing papers of 4 to 16 pages. Therefore, two separate motors and control outfits are provided, and these can be run either as two sets or as one set; in the latter case the motors and push buttons are automatically paralleled when the mechanical clutch connecting the two units is placed in gear. The four-motor con-

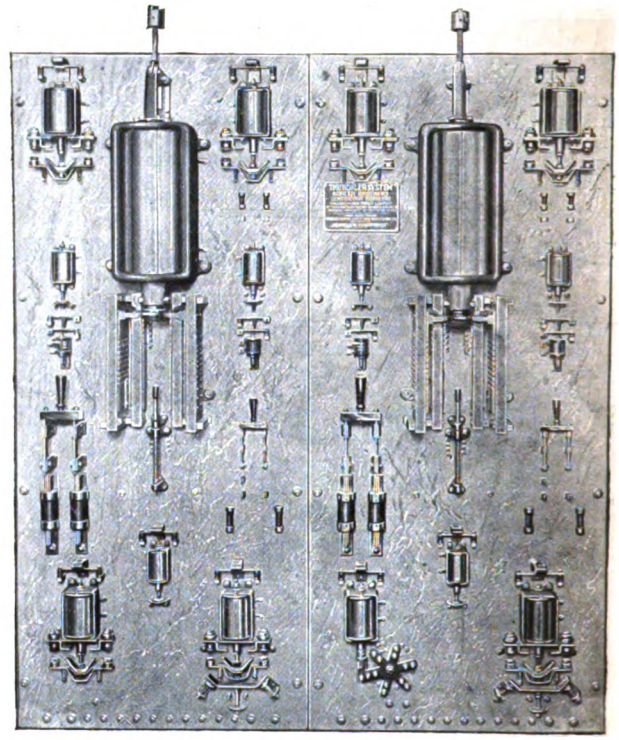

FIG. 2.—FOUR-MOTOR CONTROLLER FOR OCTUPLE ROTARY PRESS.

troller used with *The Times* press, is shown in Fig. 2, and a push-button box is illustrated in Fig. 3.

The chief features of the "Kohler" system of control are as follows:—For putting on blankets or plates, the cylinders can be brought to any desired position, and a movement of only ⅛ of an inch can be made. Again, the speed of the plate cylinders can be varied from ten revolutions per minute through several intermediate speeds to the maximum speed. While a press is being made up, and a pressman is working on any part of it, he can make it impossible for anyone to start the press by pressing the "safe" button. To start the machine he must press the "on" button. The "safe" button only prevents any alterations being made to the existing conditions; thus, pushing this button when running at a certain speed prevents increase or decrease of speed. To accelerate, the "on" button is pressed, and to slow down the "off" button is pressed. Pushing the "stop" button stops the machine in a few seconds. Whenever the machine is stopped the controller automatically returns to the starting-point. The time required to bring the press from standstill to maximum speed can be adjusted, but is usually twenty seconds. The time required to stop the press is only the few seconds neces-

FIG. 3.—PUSH-BUTTON BOX.

Digitized by Google

sary to prevent stripping the gears. Owing to the gradual start and graduated acceleration, the power consumption is reduced to a minimum. The control circuit, including push-buttons, solenoids, &c., is operated at the motor voltage off the supply circuit. The control boxes are well insulated, and resistances are connected in series with the solenoids to limit the control current to the necessary value.

The press is first started up on the small 10 h.p. motor through the worm gearing by pressing the "on" button, which releases a plunger, seen in the centre of either of the boards illustrated. The plunger descends slowly, cutting out the starting resistance of the small motor; its descent can be arrested by pressing the "safe" button. If allowed to descend further, the small motor reaches its maximum speed, and the large 60 h.p. motor takes up the load. The contacts behind the plunger belong to the starting resistance of the small motor, and the side contacts belong to that of the larger motor. On pressing the "off" button, the plunger rises slowly, reducing the speed and eventually, unless arrested, transferring the load on to the smaller motor in case it is desired to run at a slow speed or to move the rollers to any particular position. The starting resistances for the large motor would have to be abnormally heavy if it was necessary to run this at the slow speeds; and, moreover, the small and certain movements rendered possible by the use of the small worm-geared motor would be impossible to attain with the large motor only. Both the main and the small motors are compound-wound, and the former are provided with interpoles. A variation of speed between 550 r.p.m. and 700 r.p.m. is obtained on the main motor by shunt regulation, the rest of the regulation being by series resistances. The other solenoids on the boards illustrated are connected with the control system, and means for paralleling the control circuits of the two machines and the four motors is also provided. The main switches, shown in the bottom right-hand corners of the two boards, are controlled by the "stop" button and the overload and no-voltage cut-outs. When the main switches open, they short-circuit the motors at the same time, which brings the machines to rest in one or two seconds.

The Times plant was originally steam-driven, but two years ago, an electrically-driven rotary was installed, and, very soon, the whole of the plant will be electrically-driven. Power is taken from the Charing Cross & City Electricity Supply Co., with a stand-by from the mains of the City of London Co. The necessary change-over switchboard, and a large main distributing switchboard have been installed, the latter in a gallery in the machine-room. The main switchboard has ten panels; of these, two are change-over panels for the lighting and power respectively, three are press panels, two are motor panels, and two are lighting panels; the remaining panel contains the recording instruments. The overall length of the board is approximately 26 ft., and the height 7 ft.

Among the other installations installed by Messrs. Kohler Bros., in conjunction with Messrs. Crompton, is that of the *Statesman* in Calcutta, for which paper two complete equipments were supplied. This system of control has been in use at the printing offices of the London *Morning Post* and the *Manchester Chronicle* for some five years, and has also been adopted by the *Daily Mail* and the *Daily Mirror* in this country, by *Le Matin* in Paris, by the *Rotterdamsche Courant* in Holland, and in America by many of the leading newspapers and printers. We understand that there are over six hundred of these outfits in use, and that many have been in use for several years, giving very satisfactory results as to expenses of maintenance.

"ELECTRICAL" ACCIDENTS IN FACTORIES AND WORKSHOPS

THE annual report of the Chief Inspector of Factories and Workshops for the year 1908, which is accompanied by the sectional reports of the inspectors for various districts and by a long report by Mr. G. S. Ram, the electrical inspector, has just been issued, and may be obtained from the publishers, Messrs. Wyman & Sons (Fetter Lane, E.C.), or through any bookseller; price 2s. 4d. The sectional reports contain references to electrical matters which show the increase in the use of electric power in factories generally, and under the heading "electric accumulators" are a few complaints from various districts that insufficient precautions have been taken, particularly in dealing with prevention of dust. In the report for the North-Eastern District, two fatalities due to electric shocks were recorded. In the first case a boy stumbled and fell against an electric arc lamp which had been lowered close to the ground; in the second case a young person was entrusted with the dangerous work of painting the fittings inside a transformer station, and he accidentally touched a live wire.

Mr. Ram's report commences with some figures giving an idea of the increase as against the previous year in the use of electric power, and a table of accidents at electrical generating stations and sub-stations during 1908. Three non-electrical fatal accidents and 346 non-electrical non-fatal accidents are reported, of which 35 were on private stations. Two fatal electrical accidents are recorded, one coming under the heading of "cleaning, repairing, &c., at live switchboards or other live conductors," and the other under "miscellaneous." The non fatal electrical numbered in all 90, of which 16 were in private stations. The increase in the number of accidents over the previous year is partly accounted for by the inclusion of generating stations and sub-stations of certain electric railways not included in previous tables.

Of the electrical accidents, those under the heading of "cleaning, repairing, &c., at live switchboards or other live conductors," are the most numerous. Probably, writes Mr. Ram, the greater number could have been avoided altogether, it not having been really necessary that the work should have been undertaken while the conductors were live. Several occurred to labourers or other unskilled persons when put to work in dangerous places without adequate precautions or proper supervision. In the fatal case, a labourer was set to work in a high-pressure switchboard passage-way at a cell which had been made dead, but which adjoined another where there were unprotected live conductors. No adequate supervision was given, and he was found dead opposite the live cell after he had been left ten minutes alone. In another case a pupil was cleaning a dead switch, the adjoining panel being alive at extra high pressure, and was severely injured by making a connection therewith. Three accidents from short circuit occurred through persons using metal rules. Amongst the miscellaneous accidents there were three due to the use of hand lamps, one being fatal. In this case the lamp was being used inside a boiler. The pressure was 200 volts alternating. A remarkable feature of the accidents of this class is the number which occurred on extra high pressure systems without fatal results, although in most cases the injuries were very severe, and in some cases probably caused permanent disablement.

Of the reported accidents in works other than generating stations, 12 were fatal. Two of these were attributed to unprotected conductor, &c., one to an unskilled person working on live conductors, and the remaining nine, four of which were in electrical manufacturing works, are classified as miscellaneous. The number of these accidents is less than the previous year, but the number of fatalities is greater. Accidents due to arcing of switches occurred with only a few exceptions at motor switches and starters. The injuries, burns to the hand, arm, or face, were due to the absence of any protection or to inadequate protection of the switches. The cause of the arcing was, however, various—some cases being due to the faulty construction or condition of the switches themselves, others to short circuits, &c., at the motor. Those due to the arcing of fuses are mostly due to the absence of any protection at the fuse wires. Most of the accidents in replacing fuses were due to short circuits with bare metal fuse wires owing to there being no switch by which the pressure could be first cut off from the terminals. The number of accidents in the use of portable apparatus is considerable. Fifteen of them occurred when inserting the plug of the connector into the socket. Plug connectors as ordinarily designed, continues Mr. Ram, are not satisfactory. Portable apparatus, whether a hand lamp or anything else, and its flexible wires are very liable to get damaged when not in use, a short circuit in the conductors being formed. This is not detected until the next occasion that the apparatus is brought into use. Such accidents might be entirely avoided if electrical manufacturers would give these matters consideration in the design of the plugs. Such a plug should be arranged, first, so that the flexible wires enter it from below and not at the end, so that the wires do not pass through the hand of the person using it. This arrangement offers the further advantage that the wires are not bent at the point where they enter the plug, and, further, the wires are less likely to get loose in the terminals, as persons cannot pull the plug out by means of the flexible wires. There should be a sufficiently large handle to afford a good grip. Between this handle and the live metal of the contact pins, terminals, &c., there should be a circular disc or shield to protect the user's hand in case of a flash at the moment of inserting the plug. The guard disc need not be large, for small plugs suitable for a hand lamp, 2½ in. diameter would be sufficient. The flexible wires should enter the plug on the side of the guard disc away from the handle.

The accidents through unprotected conductors are mostly of a preventable nature. In the fatal case reported as due to an unskilled person working on live conductors, a boy of 16 was instructed to reverse the connections at the terminals of an alternating current motor working at 275 volts pressure. There was no switch provided in the circuit whereby the pressure could have been first cut off.

The accidents in testing departments of electrical manufacturing works include four fatal cases. Three of the fatalities occurred in connection with pressure testing. One was due to

Digitized by Google

the inadequate guarding of a wire carrying a pressure of 20,000 volts. There was only a single bar wood fence insecurely fixed to screen off this wire and the apparatus in use from the rest of the test room. Another of the fatal cases also emphasises the necessity of adequate fencing to keep persons away from danger during pressure testing. At the testing tank in a cable works, there was a single bar barrier at the entrance to the gangway alongside the tank and danger notices were exhibited. A man employed at the test tank passed the barrier and the notices, and came into contact with a 6,000 volt lead, and was instantly killed. Another case was of an unusual kind, and appears to have been due to a very high instantaneous pressure, produced by breaking the field circuit of a large motor, giving a severe shock to a man holding the hand wheel of a rheostat in the circuit, although the hand wheel was insulated from the moving arm of the rheostat sufficiently for ordinary purposes.

One of the "miscellaneous" fatalities occurred at an electric welding plant. The man, who was a smith's striker, took hold of the end of a bar of metal which was being heated, and was killed by shock. Although the normal pressure in the welding circuit would be only a few volts, a leakage had occurred in the transformer from the primary winding where the pressure was 300 volts. In this case the welder was of a type having one insulated jaw, the other being in metallic connection with the frame. The accident could not have occurred if the frame had been properly earthed. Another accident from fatal accidents. I also investigated, on behalf of the Mines Department, an electric shock fatality in a coal mine. This occurred on a concentric system with bare outer conductors earthed at the generating station. On the branch circuit where the accident occurred there were, however, fuses on both conductors. The outer conductors had become charged up, owing to the connection with earth having become broken by reason of the fuse having blown while the fuse on the inner continued to hold. There should, of course, have been no fuses or break of continuity of any kind in the outer conductor. There was, however, a local earth connection beyond the fuses, but it did not prevent the outer conductor from becoming charged so that the man who grasped it was killed, his hand being burnt to the bone. This local earth connection was made to a water-pipe nearly 200 yards in length, partly lying in water. The connecting cable was, however, loose, both on the outer conductor and on the water-pipe, and did not, therefore make a good contact. It is unfortunately a very prevalent idea in regard to work above ground as well as in mines, that any kind of connection is good enough for earthing purposes. Joints in earth connections require just as careful making as those in conductors.

Mr. Ram then passes on to emphasise the necessity for efficient provision for earthing metal work, motor frames, &c. He points out the disadvantages of small isolated earth plates, and says that it is a better plan to run a special earth cable or copper strip with the necessary branches throughout the installation, connecting to the various metal frames and covers, &c., which require earthing, this cable or strip being itself connected to earth. It need be so connected only at one point if a really good earth is provided. In this way, in a self-contained installation, *i.e.*, one having its own generating station, no large current has to flow through the earth, the earth cable providing a low resistance path for the leakage current. If faults occur on opposite poles, the fuses protecting the branches on which they occur will blow. In the case of installations having the wires run in stout metallic tubing, properly jointed and electrically continuous, the tubing can be utilised in place of the earth cable.

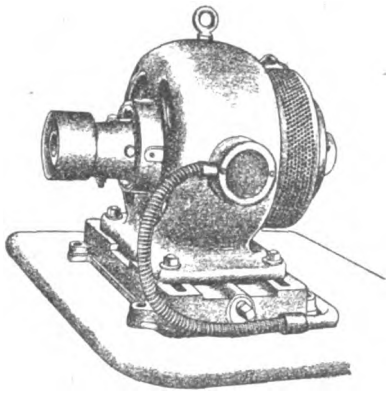

FIG. 1.

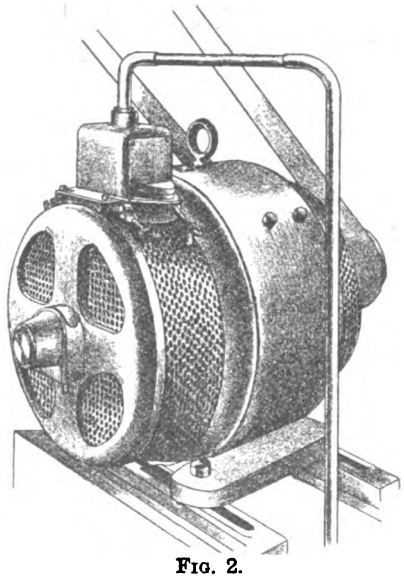

FIG. 2.

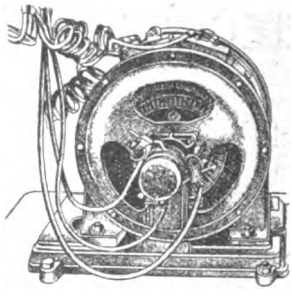

FIG. 3.

shock occurred to a man when taking hold of a leaky lamp fitting on a rising and falling pendant. The voltage was 200 alternating. He was in connection with earth through some metal he was holding with the other hand. He could not leave go, but was forcibly pulled away by others. Another accident again shows the danger of leaky lamp holders in places where the person handling them is in connection with earth. A man standing on earthed metal was about to change a lamp, and on taking hold of the holder received a severe shock, rendering him insensible.

The report then passes on to consider some examples of dangerous conditions of electrical plant which were come across in inspections during the year. For example, Mr. Ram found in electrical stations of authorised electricity supply undertakings a number of dangerous switchboard passage-ways, some where there was no protection at the high-pressure or extra high-pressure conductors and apparatus. In some the blades of isolating switches when in the "off" position, in which position, however, they were live, projected into the fairway of the passage, in two cases just at the entrance where a person would be most likely to inadvertently come into contact with them. The complete absence of any protection in the case of sub-stations of one local authority was admittedly due to the desire to keep down capital expenditure, yet in the generating station there are art tiles on the walls, oak panelling, and mosaic floor.

I found, continues Mr. Ram, on factory premises and in generating stations, examples of motor switches both for continuous and alternating current, of a dangerous type, where the hand is liable to touch live metal when grasping the handle, fixed over iron floor plates, where the user is in danger of getting a severe shock to earth, the precise conditions which have, in fact, led to fatal accidents. I found a number of cases of series incandescent lighting on 500-volt alternating circuits, with the lamp-holders and metal shades not earthed, suspended out of doors or over iron floors, where a leakage in the lamp-holder might readily, as it has done before, lead to

Mr. Ram then makes some comments on the Manchester Electrical Exhibition, the exhibits at which showed that considerably more attention is, on the whole, now being paid to the question of the safety of the persons by whom the apparatus will be used.

In many factory installations, where the wiring may be well carried out in good metal tubing, there is frequently a gap between the end of the tubing and the terminal box of the motor, where three or four feet of the cables is left entirely unprotected. These unprotected tail ends of the cables frequently get trodden on, or otherwise damaged, and become a source of trouble and sometimes of danger. The excuse for these loose wires is generally that the motor may require to be shifted on its bed, at any rate where it drives machinery by a belt, and that it is therefore impracticable to take the rigid tubing up to the terminal box of the motor. One firm had an excellent exhibit of motors, showing how this difficulty can be readily overcome. The end of the rigid tubing and the terminal box are connected by flexible metallic tubing, properly secured at each end by a suitable metal union. The wires pass through this flexible tubing, and the position of the motor can be adjusted without difficulty (*see* Fig. 1). Fig. 2 shows another method for accomplishing the same object used in several large factories. The metal tube containing the cables is rigid, and is securely attached to the terminal box of the motor. This box is capable of adjustment in regard to the

Digitized by Google

motor, allowing the latter to be moved sufficiently for belt-tightening purposes, the connections within the box being flexible. Besides making a far better and safer job, these methods incidentally add greatly to the neat appearance of the work: compare Fig. 3, which shows a class of work frequently found.

The report concludes with a reference to the establishment of the new Home Office Regulations, which come into force on July 1st next, except as regards electrical stations, where they do not generally come into force until January 1st, 1910. Mr. Ram hopes that these regulations will have the effect by improving the standard of work generally of reducing the number of preventable accidents.

PROSECUTION OF FOUR ENGLISH TELEPHONE ENGINEERS IN ANTWERP

TOWARDS the end of March, 1908, four young English telephone engineers who were leaving the employment of the Bell Telephone Co., in Antwerp, to take up an engagement with the telephone department of the General Electric Co., at Manchester, were arrested on the charge of stealing documents belonging to the Bell Telephone Co. Considerable excitement was occasioned in the English colony in Antwerp by the fact that they were retained in prison for about a month, at the end of which time they were released on £800 bail.

The four telephone engineers, whose names are Cecil Cowan, Frederick Burton, Horace Hogarth, and Richard Robinson, and whose ages are from 23 to 25 years, have now returned to Antwerp to take their trial, which commenced last Thursday, and continued on Friday and Saturday.

It is stated that the three first-named stole trade secrets or plans, drawings, important or confidential documents, and various objects, such as telephonic accessories and drawing paper, and that Richard Robinson stole trade secrets, or, at all events, one important or confidential document.

In defence it is stated that the documents, &c., found in possession of the accused were either their own property or were taken away in error, and that in any case the imputations against the accused are erroneous. After the evidence of the police officer who arrested the accused and took possession of the documents in dispute, and formal evidence by one of the directors of the Bell Co., an expert, Mons. Cornet, was called. For the accused, it is contended that in the most recent treatises on telephony are to be found all the details which are contained in the documents they are said to have stolen, whereas Mons. Cornet's evidence was directed to prove that these publications do not give details of practical applications and all the special combinations which form the trade secrets alleged to have been stolen.

Mons. Pierard, Chief Engineer to the Belgian Government Telegraphs and Telephones, whose evidence was felt to be much in favour of the accused, stated that engineers made a practice of making notes, and that he himself possessed documents belonging to the State.

Mons. Damoiseau, of Brussels, who gave expert evidence on behalf of the accused, said that the documents which, it is alleged, have been stolen, could not lead to practical improvements in any other system but that of the Bell Co. He exhibited a book sent from London, exactly similar to a book which had been seized as one of the stolen documents.

Mr. Connor, Manager of the Telephone Department of the General Electric Co., of Manchester, created a good impression in giving his evidence. To quote the *Matin*, of Antwerp, "He is a phlegmatic Englishman, a fine type of the race, very strong, saying frankly what he knows, and weighing his expressions." He said that he was formerly Chief Engineer to the Bell Telephone Co., and had supervised a number of important contracts in Brussels and elsewhere. He also said that there had never been any secrets at the company, and in his opinion the documents in question were of no value. He maintained that trade secrets in telephony were an impossibility. In conversation with him, the accused may have said that things were done in this way or that way at the Bell Co., but no information of that sort could be of any value to him. He spoke highly of the technical ability and moral conduct of the accused. On being asked whether he had not tried to take away engineers from several competing companies, Mr. Connor vigorously protested against insinuations that were irrelevant to the case, and said that he had made an offer to one engineer whom he knew to be particularly competent, but others had offered their services themselves. The case was adjourned from Saturday to Wednesday, and had not yet concluded at the time of our going to press.

The account of the proceedings given above is partly taken from telegrams to the English daily papers, and partly from the Antwerp *Matin*.

LOCAL NOTES

ABERDEEN: *Electric Wiring Regulations.*—The Corporation have approved additional regulations for wiring, and for the use of alternating current supply. Special rates are to be quoted for the supply of electrical energy to the Aberdeen Royal Asylum.

AUSTRALIA: *Rochester* (*V.*).—A contract for an electric lighting scheme has been signed, and work upon it has been commenced. The contractors are Messrs. Franki & Co., of Sydney.

BLACKBURN: *Electric Lighting Accounts.*—In his report upon the municipal electrical undertaking for the year to March 31st, Mr. P. P. Wheelwright, the Borough Electrical Engineer, states that the year has been a period of depression, to a large extent attributable to the general falling off of trade, and also to the use of more economical methods of illumination. Nevertheless, the net financial result upon the Blackburn undertaking still shows a fair profit. The income amounted to £55,156, and the expenditure to £18,287. Capital charges absorb £15,893, leaving a net profit of £976, compared with £1,443 in the previous year, and £1,528 for the year before. The reserve fund now stands at £3,400, but Mr. Wheelwright considers this altogether inadequate, taking the capital outlay of the undertaking into consideration, and he recommends the committee to transfer the surplus from the year's working to the credit of this fund. During the year 4,212,000 units have been sold, an advance of 70,000 units on the previous year; the number of consumers has increased from 1,700 to 2,000. The total connections in equivalent of 30 watt lamps is 175,550.

BRIGHTON: *Electric Lighting Accounts.*—The accounts of the municipal electricity undertaking for the year to March 31st show a net profit of £564 against a loss of £3,657 in the previous year. The revenue for the year increased from £88,082 to £88,815, whilst the expenditure was reduced from £46,755 to £43,572. Capital charges absorb £44,677. The expenditure during the year amounted to £6,170. The number of units sold were 8,037,711 against 8,002,376 in the previous year. Total costs were 1·12d. per unit against 1·26d. per unit in the previous year. The number of 8-c.p. lamps, equivalent, connected was 333,143 against 319,628, and the number of consumers now is 4,773 against 4,523 in the previous year.

Supply for Electric Omnibuses.—Arrangements have now been completed for supplying electrical energy to the new garage of the Brighton & Hove Omnibus Co. for the purpose of charging the batteries of the new electrically-driven omnibuses which are to be put into service by the company.

CARLISLE: *Electricity Accounts.*—The revenue accounts of the electricity department for the year to March 31st shows a gross profit of £6,851, and after meeting capital charges, there is a net surplus of £2,222. Last year the credit balance was £235.

CROYDON: *Electricity Charges.*—The Lighting Committee recommend that from June 30th the flat rate for electricity supply be reduced from 4½d. to 4d. per unit.

EXETER: *Tramway Accounts.*—The accounts of the municipal tramways undertaking for the year to March 31st shows receipts of £15,873, against £15,420 for the previous year. The total working expenses were £10,913, the expenses per car mile being 6¼d. After meeting capital charges, the debit balance brought over from the previous year has been reduced by a few shillings.

FALKIRK: *Electric Supply.*—A special Committee has been appointed to consider and report on the whole question of electric supply in the borough.

GLASGOW: *Tramway Receipts.*—The receipts from the Corporation tramways for the year to May 31st were £890,000, or £18,000 less than the previous twelve months.

GLOUCESTER: *Electricity Accounts.*—The accounts of the electricity department for the year to March 31st show an income of £12,353 and an expenditure of £6,738. After meeting capital charges, there is a balance of about £10, compared with a deficit of £1,206 for the previous year. The total number of units sold during the year was 1,390,253, compared with 1,320,782 in the previous twelve months. During the year, the equivalent of 4,514 8-c.p. lamps were connected to the mains. The cost per unit sold has dropped from 1·38d. to 1·13d.

GRAVESEND: *L.G.B. and Proposed Loan.*—A letter has been received by the Corporation from the Local Government Board with reference to the application for sanction to borrow £6,000 for purposes of the electricity undertaking. The Board regard the failure to supply details of the excess expenditure on the undertaking as most unsatisfactory. They gather that the difficulty arises from the fact that proper accounts of the capital expenditure have not hitherto been kept, and from the practice of applying loan monies to various items of expenditure as they arise, without regard to the specific purposes for which each of the loans was sanctioned. In the circumstances the Board will not be prepared to consider further the application now before them unless the Town Council give an undertaking by resolution (of which a copy should be forwarded to the Board) that in future a separate account will be

kept of the expenditure under each loan sanction. The Electricity Committee recommend that the request of the Local Government Board be complied with, and that the accounts be kept as requested by them in future.

HANDSWORTH: *Tramway Inspection.*—Major Pringle officially inspected the Handsworth electric tramways on Thursday.

HEYSHAM: *Provisional Order.*—In answering a communication from the Council regarding the Board of Trade's recent decision to revoke the Electric Lighting Order, the Board state that they see no reason to alter their decision.

LANCASTER: *Electric Lighting Accounts.*—The accounts of the electricity undertaking for the year to March 31st show receipts amounting to £9,754, against £9,881 for the previous year. After meeting expenditure and capital charges, there is a net profit of £711, against £1,078 for the previous year. A sum of £700 has been transferred to relief of rates.

Tramway Accounts.—The tramway accounts for the year to March 31st show a deficit of £3,235 after meeting capital charges. In presenting their report, the Committee draw attention to the imperative necessity for providing a substantial depreciation fund. At present the sum available is only £1,000, whereas from £8,000 to £10,000 is considered necessary.

LONDON: *Fulham: Electricity Accounts.*—For the twelve months ended March 31st, there was a surplus on working the electricity undertaking of £3,573, as against £1,408 in the previous year. From the first-named amount, however, there must be deducted, in accordance with the requirements of the District Auditor, the accrued proportions of principal and interest from the date of last payment to March 31st, 1909, although such payments are not made until some considerable time later. These accrued proportions amount to £1,695, leaving a net surplus of £1,914, to which should be added £408, last year's surplus. The Electricity and the Finance Committee have agreed as to the advisability of transferring £2,000 of the available surplus this year to the machinery maintenance and reserve fund, bringing the credit balance of this account up to £5,068.

Testing Stations.—The Committee have received notice from the London County Council requiring the local authority to establish and maintain six testing stations for electricity. The committee were advised that to carry out these requirements would entail considerable expense. The Town Clerk has been requested to draw the attention of the London County Council to the efficiency of the Fulham electricity supply, and the regularity of the pressure and the extremely small number of complaints received. Other Metropolitan Borough Councils possessing electricity undertakings are to be communicated with with a view to joint opposition to the proposed requirements of the London County Council.

LYME REGIS: *Electric Supply.*—The Lyme Regis Electric Light & Power Co. commenced supply on Tuesday. Underground cables have been laid in the principal streets, and overhead mains elsewhere.

NEW BRUNSWICK (CANADA): *Large Power Plant.*—The contract for constructing an electrical plant at Grand Falls on the St. Johns River in New Brunswick, where there is a fall of 135 feet, has been granted to a New York firm. The plant is expected to cost £1,000,000, developing 120,000 h.p., and power will be furnished to numerous towns in Maine and New Brunswick.

NEWTON-IN-MAKERFIELD: *Electric Lighting Order Revoked.*—The Board of Trade have revoked the electric lighting provisional Order granted to the Council in 1903.

RANGOON: *Electric Supply.*—The Governor-General has granted a licence to the Rangoon Electric Tramway Supply Co. for the supply of electricity.

SEVILLE (SPAIN): *Electric Supply.*—A Consular report upon the trade of Seville for 1908 states that a German company enjoys a practical monopoly of providing electric power for Seville. It is now completing the installation of large works on the Prado de San Sebastian, which will be able to supply three-phase current to the surrounding district. The company supplies both alternating and continuous current. Another company, called La Hidro Eléctrica del Guadiaro, has much local support. It will obtain power from the falls in the mountains of Ronda. When this company is in a position to enter into competition there should be a demand for electrical plant of all kinds, offering an opportunity for British enterprise. Details of the importation of electrical dynamos show that 49 tons came from Germany, 116 tons from Belgium (these also being of German origin), 27 tons from France, and 2 tons from the United Kingdom. The large imports from Germany are accounted for by the construction of the works above mentioned.

SUNDERLAND: *Tramway Accounts.*—The accounts of the municipal electric tramways undertaking for the year to March 31st shows a balance of £3,723. The receipts, which amount to £60,224, are the lowest since 1903. The number of passengers carried during the year, namely, 14,857,779, is less than the number carried in the previous year by 2,130,119. Of the total net profits, the sum of £2,640 has been allocated to reserve and renewals fund, £472 for cars and the Wheat Sheaf offices, and £420 for the Roker Baths siding. The percentage of working expenses to receipts were 63·35, and the revenue per car mile was 9·79d.

Electricity Accounts.—The report of Mr. A. S. Blackman, the City Electrical Engineer, dealing with the electric supply undertaking for the year to March 31st, states that the revenue amounted to £48,480, compared with £58,203 in the previous year. The gross profit, however, in spite of the falling-off of revenue to the extent of £10,000, was £26,151, compared with £23,121 in the preceding twelve months. This fact, Mr. Blackman considers, indisputably demonstrates the soundness of the undertaking. The decrease on the whole output is 23·8 per cent., whilst the revenue is reduced by 17 per cent. This shows, the report states, that the average price obtained has been better, due to the falling off in the industrial or low-priced units being considerably greater than the decrease in the other departments. With regard to the reduction in working expenses a saving of £5,487 has taken place in coal, oil, and repairs, and it is considered that, with the return of the industrial demand, working expenses can be further substantially reduced. After meeting capital expenditure, however, there is a deficiency of £2,965 against £1,908 in the previous year.

WESTHOUGHTON: *Electric Lighting Order.*—The Electric lighting provisional order in the hands of the Council has been transferred to the Lancashire Electric Power Co.

WILLESDEN: *Bulk Supply.*—Mr. J. F. C. Snell has reported to the Council upon the offer made by the North Metropolitan Electric Power Supply Company as to the proposed revision in the rates for bulk supply. The report has been referred to the Electricity Committee.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

BARKING.—The Electrical Engineer has been instructed to obtain quotations for a 200-kw. alternator.

CARLISLE.—The Corporation invite tenders for underfeed type automatic stokers for Lancashire boilers, superheaters, and a 300-kw. mixed pressure direct-current turbo-generator. Particulars from the City Electrical Engineer, and tenders by June 14th.

DUNDALK.—The Urban Council is about to apply for sanction for a loan of £25,000, of which sum £20,000 will be devoted to electric lighting schemes. The latter provides for a suction gas-driven plant, including three 75 kw. sets, at a total cost of £14,653 for power, station, mains, which will be underground in the principal thoroughfares, flame, arc, and metallic filament lamps. The committee in charge of the scheme recommended the adoption of the scheme of Messrs. Miller, Wilson, & Pegg, Belfast, and the scheme has been approved of by Sir A. B. W. Kennedy.

GLASGOW.—Tenders are invited for various works in connection with the proposed alterations and additions to the Port Dundas Electricity Station, including the erection of an electric goods elevator. Particulars from Mr. W. W. Lackie, electrical engineer, 75 Waterloo Street, Glasgow, and tenders by June 16th.

GRIMSBY.—The Borough Electrical Engineer has been authorised to obtain tenders for superheaters.

HEREFORD.—A Local Government Board inquiry was held last week into an application by the Corporation for sanction to borrow £8,000 for electrical extensions.

OLDHAM.—A Local Government Board inquiry was held yesterday into an application by the Council for sanction to borrow £10,250 for electrical extensions.

SALFORD.—Tenders are invited by June 14th for a battery, together with booster and switchgear. Particulars from the Electrical Engineer, Mr. V. A. H. McCowen.

WEST HAM.—Application is to be made to the Local Government Board for sanction to borrow £5,000 for mains and services during the ensuing twelve months.

WILLESDEN.—An additional cable is to be laid between Dollis Hill Lane and Melrose Avenue, and an extension thereof to the sub-station in Salusbury Road, at a total estimated cost of £3,050.

WORTHING.—A Local Government Board inquiry was held on Tuesday into an application by the Council for sanction to borrow £3,900 for electrical extensions.

Miscellaneous

CLACTON.—Tenders are invited for stores during the ensuing twelve months, including electrical service fittings, joint box compound, &c. Particulars from the Clerk to the Council, and tenders by June 16th.

DEVONPORT.—Tenders are invited for stores for the electricity department. Particulars from the Electrical Engineer, Newport Street, East Stonehouse, Devon.

HASTINGS.—One hundred and thirty street gas lamps are to be converted to electric lighting, at an estimated cost of £500.

ITALY.—The municipal authorities of Rome will shortly invite tenders for the construction and working of two electric

Digitized by Google

tramways in that town. It is estimated in this connection that the purchase of rails and accessories alone will involve an expenditure of about £14,600, the supplying of which material will be open to international competition.

LEEDS.—The Tramways Committee invite tenders for a 100 h.p. motor. Particulars from the General Manager, and tenders by June 8th.

SOUTH SHIELDS.—The Tramways Committee invite tenders for stores. Particulars from the Manager and tenders by June 14th.

YORK.—In order to supply electrical energy for the light railways, extensions will be necessary to the switchboard, at a cost of £550. An application is to be made to the Local Government Board for a loan.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

E.—School, Fairclough Street, St. George-in-the-East (£15,991). Builders, Holliday & Greenwood, 144A Loughborough Park, Brixton, S.W.

School, Southgate (336 places). H. G. Crothall, Architect, Middlesex Education Committee, Guildhall, Westminster, S.W.

N.E.—Roller skating rink, Kirkdale Road, Leyton. Architect, P. Cornish, 64 High Road, Leytonstone, N.E.

Fire station, Wood Street, Walthamstow. E. Morley, Surveyor, Walthamstow U.D.C.

N.W.—School, Torriano Avenue, St. Pancras (£12,530). Builders, E. Lawrence & Sons, Wharf Road, City Road.

PROVINCES.

BELFAST.—Additions to Purdysburn Asylum (£60,000). Architects, Watt & Tullick, 77A Victoria Street, Belfast.

Residence, University Square (£1,000). Architect, W. Fennell, Scottish Buildings, Belfast.

Block of offices. Architect, S. Stephenson, 83 Royal Avenue, Belfast. Builders, McLaughton & Harvey, Belfast.

BURNLEY.—Skating rink. Architect, C. Riley, Hargreaves Street, Burnley.

DENBIGH.—Tenders are invited for fitting the North Wales County Asylum with telephones, fire alarms, &c. Particulars from the Clerk to the Committee, Denbigh.

DUBLIN.—A Committee has been appointed to consider the question of having the Trades Hall wired for electric lighting.

FRIERN BARNET.—School, Holly Park (£4,888). Builders, Mattock Bros., Winkfield Road, Wood Green, N.

GLASGOW.—Tenders are invited by June 19th for electric motors, &c., in connection with the oxidiser plant at the Shieldhall outfall works. Particulars from the office of Public Works, City Chambers, and tenders to the Town Clerk.

NORTH SHIELDS.—Concert hall. Architect, J. Meadows, Howard Street, North Shields.

SOUTH SHIELDS.—The new women's imbecile wards at the workhouse are to be wired for electric lighting.

STOKE-UPON-TRENT.—Tenders are invited for the wiring of a portion of the Cottage Homes by the Board of Guardians. Particulars from the Clerk at the Union Offices, Stoke-upon-Trent, and tenders by June 9th.

TORQUAY.—Wing at Hydropathic (£5,293). Architects, Waymouth, Johnson & Webber, Tormoham Manor House, Torquay. Builder, E. P. Bovey & Son, Torquay.

WARRINGTON.—Skating rink. Architect, Garnett & Wright, 45 Sankey Street, Warrington.

WEST HARTLEPOOL.—New block, Henry Smith School (£12,000). Architect, J. Garry, 47 Church Street, West Hartlepool.

WIGAN.—Institute, Platt Bridge (£2,000). Architect, J. Thornley, 45 Market Street, Darwen.

WREXHAM.—School (£3,700). J. G. Burrell, Market Place, Durham.

YORK.—The City Electrical Engineer is to report upon the cost of a scheme for the electric lighting of the proposed light railway routes.

Diesel-Engine Reserve Plant.—A 1,100 h.p. Diesel-engine generating station is to be installed as a reserve for the Lucerne-Engelberg electricity supply system, at a total cost of approximately £11,000. The water-power station was described in ELECTRICAL ENGINEERING of September 19th, 1907, Vol. II., page 459, and the transmission system in the issue of March 12th, 1908, Vol. III., page 389.

Telegraph Wires Cut in France.—On Monday evening a number of telegraph and telephone wires were wilfully damaged in various parts of Paris and outside Nancy. It is stated that these acts are the result of circulars issued by a Paris anarchist organisation inciting the reader to damage the State-owned telegraph and telephone lines, and giving instructions how to carry this into effect.

TENDERS RECEIVED AND ACCEPTED

AUSTRALIA.—The tender of Messrs. Staerker & Fischer, of Melbourne, has been accepted for the supply of an electrically-driven air compressor for the Cassilis Gold Mining Co., Victoria. The air compressor, which will supply 1,600 cubic feet of air per minute, at a pressure of 110 lbs. per square inch, is one of Messrs. Bellis & Morcom's vertically enclosed type, the motor being by the A. E. G. Co.

BRIDLINGTON.—The tender of Mr. M. H. Fell, of Scarborough, has been accepted for extensions to the boiler-house at the Council's electricity works. Nine tenders have been received for a Lancashire boiler, and that of Messrs. Holdsworth & Sons, of Bradford, at £648 10s., has been accepted.

LONDON: *London County Council.*—The tender of Messrs. G. Hayward & Co. has been accepted for the supply and fixing of 78 movable platforms for car cleaning at the Hackney Car Shed.

L. & N.W. RAILWAY.—Messrs. William Geipel & Co. have secured the contract for the London & North-Western Railway Co. for the whole of the carbons required during the year ending June 30th, 1910, including open type, enclosed type, and flame carbons of Henrion make, for whom this firm are sole representatives for the United Kingdom. We understand that the contract is for 1,170,000 carbons.

WALTHAMSTOW.—The Council has accepted the tender of W. T. Henley's Telegraph Works Co., Ltd., for a supply of paper-insulated cables.

COMPANIES' MEETINGS AND REPORTS

JOHNSON & PHILLIPS.—The profit for 1908, after providing for bad and doubtful debts and charging to revenue £3,427 for maintenance of buildings, &c., amounts to £16,910, including £6,873 brought forward. Debenture interest, reserve *re* debenture sinking fund, directors' fees, depreciation, &c., absorb £16,229, leaving a balance of £681, which is carried forward. The directors report with regret a considerable falling off in the profits, owing to low prices and to the general depreciation. Their cable business, however, shows signs of a decided improvement, which is considered highly satisfactory, forming, as it does, the major part of the business. At the annual meeting on Thursday the report and accounts were adopted. Mr. R. W. Blackwell, the chairman of the company, who presided, stated that the fall which had occurred in the business was practically wholly due to the stagnant condition of the electrical manufacturing industry. The cable business, which had for many years been the backbone of their concern, had been well maintained, and it was the directors' belief that this would continue to prosper. In fact, there were signs that the current year would be very much in excess of what it was during the past year, in respect of the cable industry. With regard to the manufacturing side, the directors were especially satisfied with the appearance of the new form of arc lamps which had been evolved by Mr. James Brockie, who had really done all the research work in connection with the Brockie-Pell arc lamp. The new lamp was about to be placed on the market in both the magazine and flame types, and they expected there would be a considerable trade in these.

BARNSLEY & DISTRICT ELECTRIC POWER CO.—The report for 1908 shows a net profit of £2,015, after adding £262 from the previous accounts. After adding £200 to depreciation account, £500 to sinking fund for redemption of loans and debentures, and meeting preference dividend for the year, there is a balance of £196, which is carried forward.

PERTH ELECTRIC TRAMWAYS.—The report for 1908 shows a gross profit of £28,720, against £31,176 for the previous year. After meeting interest and sinking fund on the first and second debentures, there is a balance of £12,099, including £945 brought forward. A dividend of 5 per cent. is recommended on the ordinary shares, carrying forward £1,099.

ELECTRIC TRACTION CO. OF HONG KONG.—The accounts for the year to December last show a considerable decrease in traffic receipts over those of the previous year. After meeting all working expenses and debenture interest, there is a profit of £4,286, including the amount brought forward. The sum of £4,000 has been allocated to depreciation and renewals, bringing this fund to £16,000, and the balance is carried forward.

ARON ELECTRICITY METER.—The report for the year ended March 31st, states that, after providing for general charges and depreciation, there is a net profit of £20,067, making, with the balance carried forward from last year, a total available profit of £24,039. The directors recommend the payment of a dividend of 7 per cent. on the preference shares and a transfer to the reserve towards goodwill and patents of £5,000, leaving to be carried forward the balance of £6,549.

PARA ELECTRIC RAILWAYS AND LIGHTING.—At the annual meeting on Thursday, the report and accounts were adopted. The chairman, Sir William Evans-Gordon, stated that as the last of the mule-drawn cars only disappeared in June of last year, the full effect of electric traction could not be judged by the accounts for the year. Receipts from the tramways for

Digitized by Google

the full year to November 30th were £139,509, compared with £137,098, and for the lighting business the receipts were £65,802, compared with £67,485 for the previous year. The total expenses on the two undertakings were £152,627, against £162,951. The gross profit was £52,674, against £41,632 for the year to November 30th, 1907. Since the contract for the construction of the lines was carried out, and the outstanding questions between the different parties interested were settled, the Board called in Mr. Laffin, until recently manager of the Manila Electric Railroad and Lighting Corporation, to report upon the manner in which the contract has been completed. Mr. Laffin reported favourably upon the whole business of the company.

CALLENDER'S CABLE & CONSTRUCTION CO.—At the annual general meeting on Thursday the report and accounts given in our issue for May 20th were adopted. Mr. H. Drake, chairman of the company, presided. Mr. T. O. Callender, the managing director, said that the year 1908 would long be remembered as an exceedingly bad one, especially in the engineering trade, for in addition to strikes in the north and in Lancashire the year had been marked by great financial stringency. During the latter part of 1908 there had also been a bitter warfare between the leading electrical manufacturers, and contracts had been carried out at shocking prices. It had not been a question of leaving a profit, but of how small the loss would be. This bitter warfare, however, was dying out.

METROPOLITAN AMALGAMATED RAILWAY CARRIAGE & WAGON CO.—At the annual meeting on Thursday the report and accounts were adopted. The year's working has resulted in a profit of £323,584, of which £100,000 have been carried to reserve. A dividend of 10 per cent. per annum is declared upon the ordinary shares, together with a bonus of 1s. per share, carrying forward £55,932. The reserve fund now stands at £450,000.

PARLIAMENTARY INTELLIGENCE

NORTH-EAST LONDON RAILWAY BILL.—This Bill was before the Unopposed Committee of the House of Commons last week. It proposes a further extension of one year in which to raise the capital for the construction of the electric railway authorised in 1905 from the City to Waltham Abbey. When the Bill was originally passed, a clause was inserted imposing upon the promoters the raising of half the capital within twelve months, but a number of extensions of time have since been granted. Last year the Chairman of the Unopposed Committee stated that the promoters must not come for a further extension for this purpose. In introducing the Bill, however, last week, the Parliamentary agents apologised for applying once more for an extension of time, the reason being that the unfavourable condition of the money market had prevented the capital being raised. The contractors for the line were prepared to take £800,000 of stock, and the promoters were advised that the conditions for raising the capital were rapidly becoming more favourable. The Chairman stated that the Committee would require financial evidence on this point, and the consideration of the Bill was adjourned.

PROGRESS OF ELECTRICAL BILLS.—The Gateshead and District Tramways Bill was read a second time in the House of Lords last week.

Electric Lighting and Traction in Vladivostock.—The *Financial News* states that for some time past the City of Vladivostock has been anxious to instal electric light and traction undertakings among a number of other public improvements. A draft agreement has now been completed with Messrs. White & Co., of London, which provides for the placing in London of a 7 per cent. loan for 6,000,000 roubles. The firm will carry out and control all the undertakings, the profits of which are guaranteed to pay the loan interest.

Wireless Telegraphy.—In compliance with the judgment of the Court of Chancery, confirmed by the Court of Appeal, the Marconi Company is now equipping Lloyd's station at the North Foreland, and when this is in operation, the present Marconi station there will be disestablished.

The Puget Sound Tugboat Co., of Seattle, Washington, have recently had all their tugboats fitted with wireless equipments for the purpose of maintaining communication between the tugs and land. Ships desiring to communicate with their owners can do so on arrival off the coast, through the medium of the equipments on the tugs, at moderate rates.

A British Consular report states that a French company is now engaged in erecting a wireless station at Puntales, Cadiz, for communication with others 1,850 miles distant, the Canary Islands being the chief objective. The telegraph office at Cadiz is to be connected with the Puntales station.

The Direct West India Cable Co., Ltd., have obtained a license from the Jamaica Government for a coast wireless station. Both the arc and spark systems will be tried in order to see which will be most satisfactory to West Indian climatic conditions. According to the license the installation must be complete by August 25th next. The radius of the station will be 300 miles.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net. c.i.f. port of arrival, quoted on Tuesday night, was £61 10s. to £62 per ton (last week £60 15s. to £61 5s.).

LONDON WHOLESALE HARDWARE CLUB.—A river trip is being arranged for July 10th, and those desirous of taking part are requested to communicate with the Secretary at Royal London House, Finsbury Pavement, London W.C. We have received a pamphlet which sets out the objects of this club. It is a trade-promoted organisation aiming for unity and co-operation in the hardware and allied trades, and all interested should apply as above for a copy.

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—Mr. A. G. Robson, of 60 Pilgrim Street, Newcastle-on-Tyne, has been appointed liquidator in the winding-up of the Eldon Electric Co., Ltd., in succession to Mr. W. Sparks, who has resigned.

A creditors' meeting of the General Electric Sign & Engineering Co., Ltd., will be held at the offices of Messrs. Hayes & Co. 28 Basinghall Street, London, E.C., on June 10th, at 2 p.m.

A meeting of the Buenos Ayres & Belgrano Electric Tramways Co. will be held at 52 Moorgate Street, London, at 12 noon on June 30th, for the purpose of hearing the liquidator's report of the winding-up.

The statement of affairs in the bankruptcy of Messrs. J. G. S. Cunnington and H. P. Allison, trading as Messrs. Laing, Wharton & Cunnington, electrical engineers and contractors, Great Newport Street, London, W.C., disclosed liabilities of £6,541, and assets of £3,785. The failure is attributed to judgment against the firm for £4,000, for which the debtors stated they had received no consideration. Mr. A. Page, 28 King Street, Cheapside, chartered accountant, was appointed trustee.

The trustee in the bankruptcy of R. S. Blackburn, electrical engineer and contractor, Osborn Street, Hebden Bridge, Yorkshire, has been released.

A first and final dividend of 1s. 3d. in the £ will be paid in the bankruptcy of T. A. Evans, electrical and mechanical engineer, Swansea, on June 10th, at Government Buildings, Swansea.

A meeting of the Buenos Ayres and Belgrano Electric Tramways Co. will be held at the offices of the liquidator, 52 Moorgate Street, London, E.C., on June 30th, at twelve noon, for the purpose of hearing the liquidator's account of the winding up.

AGENCY.—Mr. G. Wüthrich, of Oswaldestre House, Norfolk Street, London, has appointed Messrs. W. B. & J. Bain, 65 Waterloo Street, Glasgow, to represent him in Scotland for the sale of machinery, plant, and apparatus manufactured by the Maschinenfabrik Oerlikon, near Zurich, Switzerland.

APPOINTMENTS AND PERSONAL NOTES

The salary of Mr. J. Downie, Chief Clerk in the Aberdeen Corporation Electricity Department, is to be increased to £200 by three yearly instalments of £15, £15, and £20 respectively.

Mr. F. H. Corson, Chief Assistant Electrical Engineer to the Blackburn Corporation, who has been appointed Chief Electrical Engineer at Gloucester, has been presented with a solid silver coffee pot by the employees at Blackburn.

MISCELLANEOUS CITY NOTES

BOMBAY ELECTRIC SUPPLY & TRAMWAYS CO.—Subscriptions are invited at 94½ per cent. for £150,000 5 per cent. second mortgage debentures, redeemable by annual drawings at 101 per cent.

MEXICAN LIGHT & POWER CO.—Dr. F. S. Pearson, the president of this company, has cabled to the London office with regard to the rumours concerning alleged difficulties in connection with the water supply at the company's power house. He states that owing to an unprecedented drought season there has been a small shortage, but rain is now falling, and all the power users in the Federal district of Mexico are being fully supplied.

MIDLAND ELECTRIC CORPORATION FOR POWER DISTRIBUTION.—The accounts for the year to December 31st, 1908, show a loss of £11,517. The debit balance on the company's working to date is £82,602.

SIEMENS BROS. & CO.—A dividend of 4 per cent. is recommended for 1908. The sum of £2,528 has been written off shares in other companies, and the pension fund has been credited with £3,459.

COMPANIES TO BE STRUCK OFF REGISTER.—Notice is given that the names of the following companies will be struck off the Register of Joint Stock Companies at the expiration of three months, unless cause is shown to the contrary:—Anglo-Iberian Electric Light and Power Co.; Carl Oppermann Electric Carriage Co.; Electric Carriage and Storage Co.; London Electric Supply (Joint Committee).

CANADIAN GENERAL ELECTRIC CO.—A dividend of 1¾ per cent. has been declared upon the common stock for the three months to June 30th.

Digitized by Google

NEW COMPANIES

PALMER & CO. (ELECTRICIANS).—Registered on April 20th, with a capital of £1,000, to acquire the business carried on at 7 Gt. Castle Street, London, as Palmer & Co., and to carry on the business of electricians, engineers, dealers in electricity, motive power and light, &c. The subscribers are G. B. Sear, 24 St. John's Road, Penge, S.E.; R. D. Marr, 68 Millais Road, Leyton. Private company. W. H. Palmer is the first secretary. Registered by McDiarmid & Son, 5 Newmans Court, Cornhill, E.C.

ARCHIBALD WATSON & CO.—Registered in Edinburgh on April 23rd, with a capital of £10,000, to purchase the business of Archibald Watson & Co., electrical engineers, brassfounders, plumbers and contractors, of 36 George St., Glasgow. The subscribers are:—Archibald Watson, 36 George St., Glasgow; David Dundas, 36 George St., Glasgow, electrical engineer. Private company. The number of directors is to be four; the first are A. Watson, W. W. Watson, D. Dundas, and G. B. Young. Remuneration £2 2s. for each meeting attended. Registered by Oswald & Son, Edinburgh.

DAVEY ELECTRIC CO.—Registered, on May 3rd, with a capital of £2,000, to carry on the business of electrical, mechanical, and general engineers, manufacturers of and dealers in electric lamps, electricity meters, electrical switches, cut-outs, and other electrical apparatus, &c. The subscribers are W. Martin Davey, Tower Building, Liverpool, consulting engineer; J. Andrews, 20 North John Street, Liverpool, accountant; C. F. Heard, Tower Building, Liverpool, consulting engineer; J. Wilson, 28 Chapel Street, Liverpool, engineer; C. P. Boucher, 28 Chapel Street, Liverpool, engineer; H. R. Jones, 24 Belgrave Street, Liscard, Cheshire, electrical engineer; S. R. Wilson, 16 Hampden Road, Higher Tranmere, Birkenhead, electrical engineer. Private company. The number of directors is not to be less than two nor more than four; the first are not named. Qualification, £100. Registered by T. T. Hull & Son, 22 Chancery Lane, W.C.

POLLAK VIRAG RAPID TELEGRAPH CO.—Registered on May 8th, with a capital of £100,500 in 100,000 preferred ordinary shares of £1 each and 10,000 deferred shares of 1s. each, to adopt an agreement with Pollak Virag Syndicate, Ltd., to carry on the business as a telegraph, telephone, and electric light and power supply company, to establish control and regulate telephone and telegraph exchanges, to transmit and facilitate the transmission of telephonic and telegraphic communications and messages, &c. The subscribers are:—H. Pettitt, 18 Austin Friars, solicitor; P. J. Hellis, 3 Merthyr Terrace, Castelnau, Barnes, clerk; A. K. Sterne, 18 Austin Friars, E.C., gentleman; A. B. Potter, 18 Austin Friars, E.C., secretary; C. H. Tolley, 18 Austin Friars, E.C., gentleman; H. E. Williams, 28 Charnock Road, Clapton, N.E., gentleman; A. G. Dobrantz, 22 Wakefield Street, Regent's Square, W.C., clerk. Minimum cash subscription, 10 per cent. of the shares offered to the public. Three of the first directors shall be nominated by the Société Generale de Telegraphic Rapide (Pollak Virag). Two of the first are H. F. Bouillon and Bela Steiner, managing director and director respectively of the said Société. Qualification, £200. Remuneration, £200 each per annum (chairman, £400). Registered by Slaughter & May, 18 Austin Friars, E.C.

CARDWELL, BOORMAN.—Registered on April 26th, with a capital of £1,000, to acquire the business of Cardwell, Boorman, Ford-Lloyd, Ltd. (in liquidation), and to carry on the business of electricians, electrical and mechanical engineers, founders, manufacturers of, and dealers in, electrical, telegraphic, and telephonic apparatus and appliances, &c. First directors: C. Stirling (chairman) and A. F. Ward (managing directors). Registered office:—Boswell Court Works, Boswell Court, Devonshire Street, W.C.

RADIUM LAMP.—Registered on April 27th, with a capital of £100, to carry on the business of manufacturers of, and dealers in, lamps and parts thereof for lighting, heating, or otherwise by the agency of electricity, gas, or other means, &c., and to adopt an agreement with R. Schreiber and J. F. Wakelin. The subscribers are:—J. F. Wakelin, 45 Adelaide Road, Hampstead, N.W., electrical engineer; P. N. B. Tibs, 18 Great Eastern Avenue, Southend-on-Sea, engineer. First directors: R. Schreiber (chairman and managing director) and J. F. Wakelin. Registered by H. H. Wells & Sons, 17 Paternoster Row, E.C.

BASTIAN ELECTRIC HEATING SYNDICATE.—Registered on May 19th, with a capital of £10,000 in £1 shares, to adopt an agreement with C. O. Bastian, and to carry on the business of manufacturers of and dealers in electric heaters and cookers and kindred appliances, founders, plumbers, gasfitters, electricians, &c. The subscribers are A. C. Newman, 188 Palmerston House, E.C., secretary; H. G. M. Smith, 2 Copthall Buildings, E.C., gentleman; P. Vandervell, 170 Palmerston House, E.C., gentleman; T. Golden, 37 Chaucer Road, Herne Hill, S.E., gentleman; C. Bastian, 2 Lea Road, Heaton Moor, Stockport, electrical engineer; W. T. Hick, 2 Church Court, Clement's Lane, E.C., solicitor; F. Dawson, 2 Church Court, Clement's Lane, E.C., clerk. Minimum cash subscription, £1,000. The number of directors is not to be less than three nor more than seven; the first are A. C. Newman, H. G. M. Smith, and P. Vandervell. Qualification of first three directors, one share; of subsequent directors, £100. Remuneration (except managing director), £50 per annum (chairman, £75), and 5 per cent of the profits, divided. Registered by W. T. Hick, 2 Church Court, Clement's Lane, E.C.

AUTOMOBILE ELECTRIC LIGHTING SYNDICATE.—Registered on May 15th, with a capital of £5,000 in £1 shares (2,500 deferred), to adopt an agreement with the Polkey Automobile Electric Lighting Syndicate, Ltd., for the acquisition and exploitation of certain patents or rights or privileges, and to carry on the business of mechanical and electrical engineers, generators, accumulators, distributors, and suppliers of electricity for motive power, light, heat, or otherwise, &c. The subscribers are J. Polkey, 126 Pitsford Street, Birmingham, lamp manufacturer; W. Peto, Ashstead, Surrey, electrical engineer; A. R. Lancaster, Queen's College, Birmingham, C.A. Private company. The number of directors is not to be less than two nor more than five; the first are J. Polkey, W. Peto, and A. R. Lancaster. Qualification, 200 shares. Registered office, Queen's College, Paradise Street, Birmingham.

PIRELLI.—This company was registered on May 18th, with a capital of £8.000 in £1 shares, to carry on the business of manufacturers of and dealers in indiarubber, gutta-percha, and asbestic articles, insulating materials, insulated wires and cables for use for telegraphic, telephoning, and other purposes, electric lighting, &c., and to adopt an agreement with Pirelli & Co., of Milan, Italy. Private company. The number of directors is not to be less than two nor more than seven; the subscribers are to appoint the first. Qualification, £50. Remuneration (except managing director) as fixed by the company. Registered by Ingle, Holmes, Sons, & Pott, Capel House, E.C.

SMALL POWER DYNAMO & MOTOR CO.—Registered on May 19th, with a capital of £15,000 in £1 shares, to take over the business of electrical and mechanical engineers carried on by J. Bentham, F. S. Blakey, R. Wilson, and Jane Bentham at Old Lane, Higher Openshaw, Manchester, as the Small Power Dynamo & Motor Co. The subscribers are:—J. Bentham, 97 Abbey Hey Lane, Openshaw, Manchester, electrical engineer; R. Wilson, 28 City Road, Higher Openshaw, Manchester, electrical engineer. Private company. The number of directors is not to be less than two nor more than five: the first are J. Bentham, F. S. Blakey, and R. Wilson. Qualification, £50. Remuneration as fixed by the company. Registered office: Old Lane, Higher Openshaw, Manchester.

Schutz der Hochspannungsanlagen. By H. Zipp. (Hanover: Dr. M. Janecke.) 3 marks.

Linking Up of the London Electricity Works.—In the article on page 467 of our issue for May 20th, dealing with this question, we stated that it had been resolved to appoint a Consultative Committee of twelve members, six representing the Borough Councils, and six the companies, to draw up rules of procedure. The Borough Councils have now appointed the following representatives:—Councillors W. J. Stapleton (Hackney), H. B. Vorley (Islington), H. R. Barge (Poplar), J. E. Harwood (Shoreditch), H. H. Gordon, L.C.C. (Stepney), and E. R. Debenham (St Marylebone). The list of names of the companies' representatives is not quite complete, certain of the West End companies not yet having selected their nominees.

Electric Lighting Acts (Amendment) Bill.—The Incorporated Municipal Electrical Association recently circularised its members with a view to securing the support of Members of Parliament to the Electric Lighting Acts (Amendment) Bill in its original form, namely, without Lord Avebury's amendment which was passed in the House of Lords, by which municipalities may only carry out wiring and fitting, &c., through a contractor. In view of the fact, however, that opposition to the Bill at the second reading stage may jeopardise its passing this session, and also owing to the municipalities throughout the country realising that a large number of important provisions are contained in the Bill, it is possible that it will be allowed to pass the second reading unopposed with the object of fighting the point in dispute when the Bill comes up for consideration in Committee. On the other hand, the National Electrical Contractors' Association is busy enlisting the support of members of Parliament in order to retain the clause prohibiting the wiring and fitting of premises for electric supply by municipalities except through a contractor, which was added during its passage through the House of Lords.

Digitized by Google

THE ELECTRICAL MANUFACTURE OF NITRATES FROM THE ATMOSPHERE

THE history of the practical development of this industry was well summarised in the Paper read by Messrs. W. Cramp and B. Hoyle before the Institution of Electrical Engineers in December last, in which the authors also described a series of researches on the same subject by themselves. (See ELECTRICAL ENGINEERING of December 24th, Vol. IV., page 810.) In the discussion to that Paper some mention was made of the work of the Badische Anilin- und Sodafabrik, and we are now able to publish a description of the arc furnace developed by that company, and also some further particulars of the Birkeland and Eyde furnace, and of the works of the Norwegian Nitrate Works, Ltd., in Norway, which were given in a Paper read by Mr. S. Eyde himself at the Royal Society of Arts last week. These two concerns, together with the Elberfelder Farbenfabriken and the A. G. für Anilinfabrikation, Berlin, have recently combined, and although the works already established by each company are still financed separately, and are continuing with the original furnaces, the new works which are being erected in Norway and elsewhere will be run conjointly by the four companies, and experiments are now being made with a view of determining the relative efficiency and general behaviour of the two furnaces. Future works will be equipped with the pattern of furnace which comes out best in the tests, or possibly a new pattern may be developed.

The Badische Anilin- und Sodafabrik Process.

A description of the whole process developed by this company was given in recent numbers of the *Elektrotechnische Zeitschrift* by Dr. Schönherr. The author first points out that the maximum amount of nitrogen oxide that can be formed amounts to only 5 per cent. of the volume of air at a temperature of 3,330°C., and that in practice this figure cannot be reached owing to the rapid dissociation at high temperatures. By mixing the treated air with a large quantity of untreated air, however, the rapid cooling of the gases as they leave the arc is ensured, and the tendency to dissociate diminished. The dilution of the treated air also acts beneficially, although it makes it more difficult to concentrate the oxides afterwards. The Badische Anilin- und Sodafabrik originally used a continuous-current arc, but it has been found that by blowing the air along the length of the arc in the form of a helix surrounding the arc, alternating-current can be used equally as well.

The construction of the pattern of furnace in use at present in the various works of the Badische Anilin- und Sodafabrik Co. is illustrated in Fig. 1. In this drawing, *A* is a water-cooled copper electrode insulated from the rest of the furnace; this electrode is in the form of an annular cylinder between the walls of which the water is circulated, and an adjustable iron core *B*, in the centre of this, forms the actual electrode from which the arc is struck. This core becomes covered with a film of molten ferrous oxide which slowly evaporates, preventing the rapid burning up of the core. As the core is burnt away, it is raised at intervals by hand, and the arc never reaches the copper. One core lasts about 2,000 working hours, and a new one can be put in in about 15 minutes. Supported perpendicularly over this electrode, but insulated from it, is a steel tube *C*, five or seven metres long, which is in metallic contact with the rest of the furnace. The arc is started by touching the core *B* with the iron striking-rod *D*, by means of the lever provided, and the arc is immediately blown up the side of the steel tube by the pressure of the air being blown through. If the full air pressure is employed, the arc is blown to the top and then burns continuously between the core *B* and the top edge of the tube *C*. The pressure across the arc is 5,000 volts or 7,000 volts, according to the length. Three glass windows, *G*, are provided, through the lowest of which the condition of the core *B* can be observed. The lower portion of the steel tube is provided with a number of perforations as shown at *E*, and a collar *S*, which slides over these, is connected to a lever outside. This gives a simple means of regulating the air supply. The length of the tube *C* in the 600-h.p. furnace is five metres, and that of the 1,000-h.p. furnace seven metres. As the air pressure varies somewhat, the arc does not remain at one spot, but plays about the top of the tube, sometimes falling a considerable distance down the inner surface. As continuous burning from this surface would soon destroy the tube were it not artificially cooled, this upper portion is provided with water-cooling as shown at *K* in the figure. This is so effective that the tubes show hardly any pitting after months of use.

It will be noticed that the air enters the furnace at *F*, flowing through concentric channels along the length of the furnace so as to become well heated before reaching the inlet to the arc chamber at *E*. The inlet passages are bored at such an angle that the air rushes up the tube *C* in a spiral whirl, as it has been found that this prevents the arc from striking the side of the tube, and renders it possible to keep a stable arc even with alternating current. The treated gases pass, as shown, down an outer concentric channel, and out at *H*. The whole system of concentric tubes is enclosed in a firebrick cylinder armoured with steel, and the complete furnaces are mounted vertically in rows in the works. The height of the 1,000-h.p. furnaces is approximately thirty feet. It is not essential that the furnaces should be arranged vertically, however.

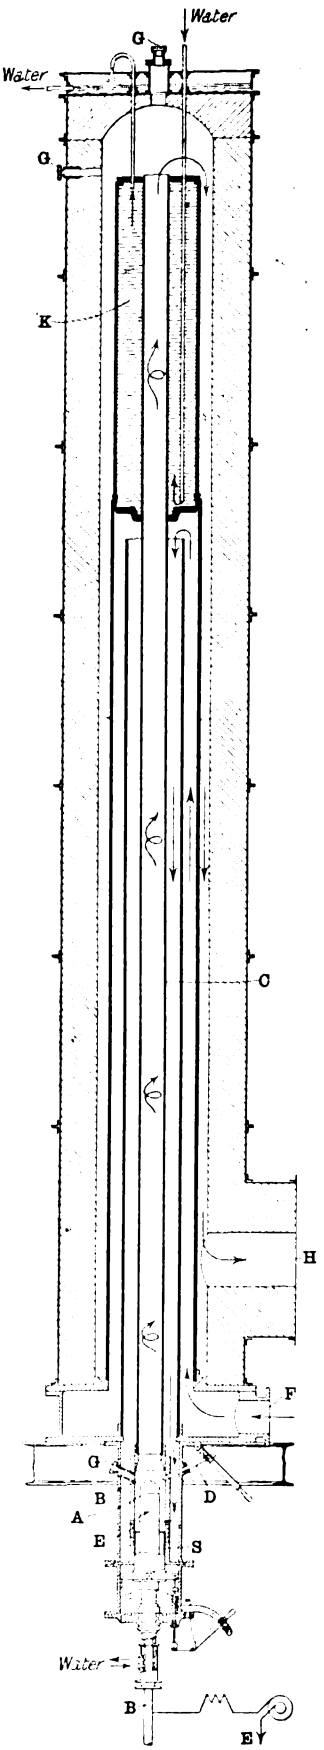

FIG. 1.—THE BADISCHE ANILIN- UND SODAFABRIK FURNACE.

An interesting point in connection with the long arc produced is that oscillograph records show that the current and pressure curves are approximately sine curves, whereas in the ordinary arc lamp and also in the case of the Birkeland and Eyde arc, there is a distinct point or hump at the beginning of every half wave. The power factor is therefore good, and in actual practice varies between 0·92 and 0·96. It is claimed that the comparatively long period of time during which the air is in contact with the arc is an advantage, as it is thought that this is responsible for the smoothness of the current curve, and also tends to raise the efficiency. The actual amount of energy utilised in the formation of nitrogen oxide is, of course, very small, being only about 3 per cent. of the total energy taken by the arc. In round numbers some 40 per cent. of the heat generated by the arc is absorbed by the cooling water; about 17 per cent. is lost by radiation; 30 per cent. is given up to boilers by the hot gases; and about 10 per cent. is extracted by water-cooling the gases after they leave the boilers. The remaining 3 per cent. is actually used in the formation of oxides. In order to save radiation losses, it has been proposed to build the furnaces in the boilers, but this has not yet been realised in practice.

The gases leave the arc tube at a temperature of about 1,200°C., at which temperature there is practically no tendency for the gas to become dissociated. In the outer channel, the temperature is about 850°C. Directly the temperature falls below 600°C., the nitrogen oxide takes up oxygen from the remaining air, and becomes the brown coloured gas, nitrogen dioxide. This conversion of the NO to NO_2 is only completed when the temperature has been reduced to about 140°C., and also takes

Digitized by Google

a certain time. The greater part of this reduction in temperature takes place in the boiler-furnaces, the steam raised by the boilers being used for concentrating the selections produced later on. The gas is then passed through absorption towers, where it is absorbed by lime water. Calcium nitrite is produced, and this can be used directly as a fertiliser. If desired, it can be converted to calcium nitrate. The nitrate contains about 18 per cent. of nitrogen, whereas the natural Chili saltpetre contains only about 15 per cent.

The first experiments of the Badische Anilin- und Sodafabrik were made at Ludwigshaten, Germany, but in the autumn of 1907 a larger works was set in operation at Kristianssand, in Norway. Power is supplied to the latter works from a water-power station, 26 km. distant, by an overhead line, at 25,000 volts, three phase. At the works the pressure is reduced to 7,200 volts, and as the furnaces are connected in star, the pressure across each is 4,200 volts. There are only three 600-h.p. furnaces in operation, however. Some 1,000-h.p. furnaces have been constructed and have given good results; the arc in the latter furnaces is seven metres long. A works four times larger than the works at Notodden (described in Mr. Eyde's Paper below) is now under construction at Rjukan in the south of Norway; this will be the first works of the combined companies. The Rjukan falls will supply the power, and ten turbines each of 14,000 h.p. are being installed. The furnace house and absorption plant will be completed some time next year. Other works are to be built in the west of Norway, where the water-power of the Matre and Tyn will be utilised. The Bavarian Government has also been approached with regard to obtaining a concession for utilising the water-power of the Lower Alz for the same purpose.

The Birkeland-Eyde Process.

In his Paper before the Royal Society of Arts, Mr. S. Eyde points out the Birkeland-Eyde process was the first to be worked on a large scale, and expresses the opinion that all commercial systems will require to employ large quantities of energy in the arc furnaces. Birkeland and Eyde's arrangement is shown in Fig. 2. The furnace contains a pair of water-cooled copper tubes 15 mm. diameter employed as electrodes. These electrodes are suitable for flames up to 750 kw. at 3,500 volts, with a gap of 1 cm., and are placed in a magnetic field of about 4,000 to 5,000 lines of force per square centimetre in the centre. This field blows the arcs into the form of a large circular fan, the maximum diameter of the flame being about 140 cms. Fig. 3 shows the form of flame employed and the connections used. The object of the magnetic blow-out arrangement is to increase the rate of cutting of the flame and the air, which is also assisted by the air blast supplied.

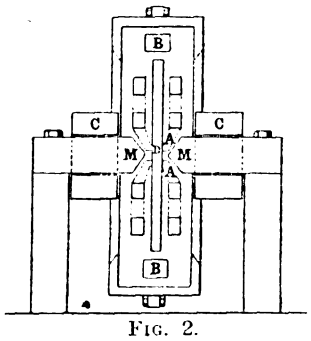

FIG. 2.

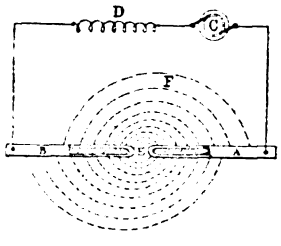

FIG. 3.

APPARATUS OF BIRKELAND AND EYDE.

Electrodes not shown.
A and *B*. Hollow Copper Water-cooled Electrodes.
C. Alternator.
D. Choking Coil.
E. Gap from 0·75 to 1 cm. long.
F. Disc of Flame up to 140 cms. Diameter.

An inductive resistance is used in series with the arc to regulate it. With alternating current, the arcs are blown out on both sides, and form a disc flame, as shown in Fig. 3. The flame disc of a 1,500-h.p. furnace has a diameter of 1·8 metres (nearly six feet). The flame burns in a circular fire-clay chamber only a few centimetres in width, and about two metres in diameter, as shown at *D* in Fig. 2; this figure also shows the position of the magnet poles. The electrodes, each of which is a hollow copper loop, enter the furnace radially. Air is blown through the flame chamber at right-angles to the disc of flame. The temperature in the flame exceeds 3,000° C., and the temperature of the escaping gases varies between 800° C. and 1,000° C. The electrodes require to be changed every third or fourth week, and the fireproof masonry every fourth to sixth month.

The furnace house of the Norske Salpeterverker (Norwegian Nitrate Works, Ltd.), at Notodden contains thirty-six Birkeland & Eyde furnaces, most of which receive power from the water-power station at Svaelgfos. This is about three miles from the Notodden works. Four turbines, each of 11,000 h.p., are installed, and power is delivered over a three-phase line at 10,000 volts, 50 cycles. The nitrous gases formed in each of the furnaces pass through two fireproof-lined gas-collecting pipes, about 2 metres in diameter, which convey the gas through the basement out to the steam boiler house. In the boiler house, the gas passes through four steam boilers, in which the temperature, which was, as mentioned, 1,000 degrees Centigrade, is reduced. The heat given off by the gas is used for concentrating the products.

The gases pass on from the steam boiler furnaces through an iron pipe into the cooling house. Each cooler consists of a great number of aluminium tubes, over which cold water runs, while the hot gases pass through them. From the cooling chambers the gases go on to the oxidation tanks, which are vertical iron cylinders, lined with acid-proof stone. Here the oxidation of the oxide of nitrogen takes place. The necessary amount of oxygen is present in the air which accompanies the gases from the furnaces. From the oxidation tanks the gases are led into the granite absorption towers. These are filled with broken quartz, which is neither affected by nitrous gases, nor by nitric acid. The gases go through the quartz packing of three such towers. Water trickles through the granite towers and this is gradually converted into a weak nitric acid. The gases are then passed through wooden towers, through which a solution of soda percolates, and this absorbs the last traces of nitrogenous gases. The finished nitric acid coming from the towers has a strength of about 30 per cent. by volume. It is passed into granite vats filled with limestone, and this drives off the carbonic acid contained in the limestone, while the nitric acid takes its place, and forms a watery solution of nitrate of lime or calcium nitrate. This solution of nitrate of lime is then pumped into vacuum evaporating apparatus. The steam required for the evaporisation is obtained from the boilers. The concentration of the nitrate solution is continued until the specific weight of the liquid shows a content of 13 per cent. of nitrogen. This solution is then pumped up into the solidification chambers, where the nitrate stiffens into a brittle, crystalline mass, hard as stone. This is broken up into lumps, and is taken into the crushing machines. The coarse powder so produced is packed in casks holding 100 kilos net weight. The nitrite solution from the soda towers, after being concentrated, is run into crystallisation pans. The crystals are separated by centrifugal means, and after drying are packed in casks. This nitrite of soda is used in the manufacture of certain kinds of aniline colours.

Mr. Eyde then gives particulars of many experiments, proving that nitrate of lime is equal to nitrate of soda as a manure. In soils deficient in lime, the nitrate of lime has proved superior.

Dr. S. P. THOMPSON, previous to the reading of the above Paper, mentioned, in introducing Mr. S. Eyde, that the original discovery that nitrogen was oxidised by the electric discharge was made at Cavendish, 125 years ago. In 1898 Sir William Crookes pointed out that as the supply of natural nitrate of soda from Chili and elsewhere was limited, there would come a time when agriculture would fail to keep pace with the food needs of mankind, unless new sources of artificial manures could be discovered. In 1903 the first three Birkeland & Eyde furnaces were working in a small factory at Notodden, and now there were thousands of horse power being utilised in the production of nitrate of lime.

Mr. JOHANNES IRGENS (the Norwegian Minister) said that the new industry was considered in his country to be of the greatest national importance. Although the utilisation of the water-power spoilt the natural scenery to a large degree, it gave much employment, and was to be preferred.

Mr. A. D. HALL (Rothamsted Experimental Agricultural Station) hoped that the effect of the competition amongst the various makers of artificial nitrogenous manures would be to lower the price. Experiments at Rothamsted had proved that nitrate of lime gave the same results as nitrate of soda.

Mr. J. ROBINSON suggested that by utilising the waste heat of furnace gases, electric power could be produced cheap enough to render the manufacture of nitrates practicable in Great Britain.

Dr. S. P. THOMPSON thought that power could not be produced cheap enough from furnace gases, as the capital cost and maintenance of the necessary plant was very heavy. When in Norway he had been struck with the financial methods in vogue with regard to these particular undertakings. Schemes which were really scientifically sound had, in this country, been made the subjects of financial speculation before they had reached the proper stage of development, and the present state of the electrical industry in this country was in great measure due to this. In Norway, the promoters of the nitrate undertaking first of all satisfied themselves as to the soundness of the process, and then, after consulting several experts from other countries, satisfied some bankers, with the result that the necessary capital was raised without appealing to the public. We could have nothing but admiration for their work, which was scientific, both in its science and in its finance.

Mr. EYDE, replying to Mr. J. Robinson, stated that even if electrical power could be generated in this country as cheap as that generated in Norway and Germany by water-power, it would not be used for the manufacture of fertilisers; there would be other industries here to which it could be applied to better purpose.

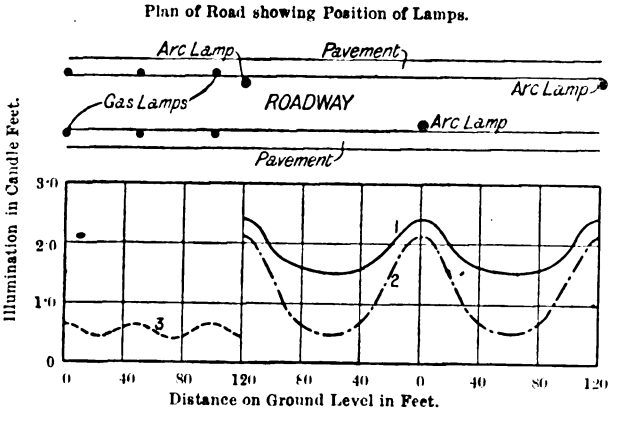
STREET LIGHTING IN BRADFORD

A Comparison of Gas and Electricity

WE have received from Mr. T. Roles (City Electrical Engineer and Manager, Bradford) some particulars of the experiments which have been made in Bradford in comparing electric lighting with gas lighting in one of the main streets, after which the City Council came to the decision to retain gas lighting. Some remarks made in a recent issue of the *Gas World* claim the result as being a victory for gas, but Mr. Roles points out that the article is very misleading, and he enables us to put before our readers the details of the comparative tests. It appears that complaints were received from the ratepayers that the lighting in a certain district was insufficient, and, in order to determine whether gas or electricity was most suitable for the increased lighting required, the Electricity Committee and the Gas Committee were each authorised to light up experimentally, for purposes of comparison, a short length of Manningham Lane.

The length of road lit by the Electricity Department is approximately 700 yards. The existing tramway standards have been utilised, an ornamental bracket having a space of 5 ft. from the post to the centre of the lamp having been fixed at the top of each alternate pole on each side of the road, in place of the ordinary finial. Eighteen Excello flame arc lamps are in use, each giving an illumination of 2,500 candle-power, arranged on each side of the road at a distance of about 40 yards apart. The brackets are fixed at a slight angle to the span wire supporting the trolley wires to allow of the lamps being raised and lowered by means of a winch, without fouling the wire. The lamps can thus be trimmed more expeditiously and with greater safety to the attendant, as no ladder is required. The height of the arc from the ground when the lamp is in position is 25 ft. 3 in., which ensures a good distribution of light. The lamps are arranged in two circuits, that on one side of the road being entirely independent of the one on the other side. By this arrangement it is possible to switch out one of the circuits at midnight, thus leaving half the illumination, which is amply sufficient during the small hours of the morning; also, in the event of one circuit being disconnected through the breaking of the cable or similar cause, the street would not be left in darkness. The 18 lamps now fixed have replaced 22 gas lamps each having two incandescent burners, the total candle-power of each gas post being about 150. This being the case, the total candle-power of the 18 lamps as compared with the 22 gas lamps they have replaced is 45,000 as against 3,300, the additional candle-power being 41,700. The Electricity Committee are prepared to supply and maintain such lamps, including current, carbons, trimmers' wages, repairs, &c., for the sum of £12 10s. 6d. each per annum. This is equal to a charge for lighting of about 6s. 5d. per yard, which is about two and a half times the cost of the gas lighting replaced, but, in view of the above figures, it is claimed that, light for light, the cost is very much in favour of the new method of illumination.



The idea adopted in the gas installation is the use of smaller units placed closer together. Along a portion of Manningham Lane, 703 yards in length, the Gas Department have 75 lamps in 19 spaces between tramway poles, fitted with three new type Bray's burners, which average 3·84 cubic feet of gas per hour, the light being 11½ ft. above the ground, and the lamps 19 yards apart. All the burners are lighted up to 11 p.m., giving, according to the present scale, 1,857 hours per annum. At 11 p.m. one-half the lamps are extinguished, and in the others one burner is left until daylight—1,933 hours per annum. The average cost of each lamp erected complete is £4 19s., and the gas used by the 75 lamps per annum is 1,886,500 cubic feet, or 25,153 cubic feet each. The estimated cost of maintenance is £91 2s. 1d., or £1 4s. 3d. per lamp. Last year 1s. 5d. per 1,000 cubic feet was received from the Finance Committee for the gas used in the lamps. At this rate the gas is worth £133 12s. 6d., or £1 15s. 7d. per lamp, bringing the total annual cost to £224 14s. 7d., or £2 19s. 11d. per lamp—6s. 4¾d. per yard of street. Taking gas at the selling price of 2s. 1d. less 12½ per cent., the total cost of 75 lamps would be £263 1s., or £3 10s. 1d. —7s. 5¾d. per yard.

In the accompanying figure are reproduced a series of curves giving the results of careful tests made by the Electricity Department, with a Simmance-Abady flicker photometer.

After the experimental lighting had been in operation for some little time, complaints were raised that the light provided was excessive, and, in view of the high rates, extravagant. A Sub-Committee, composed of the Chairman and Deputy-Chairman of the Finance Committee, inspected the lighting, and gave instructions that only one-half of the gas lamps were to be used in future, and that one series of the arc lamps was also to be left out. It was also decided to make experiments with gas lamp posts of varying heights. Upon these latter being erected, the Sub-Committee again inspected the lighting, and decided in favour of gas lamps of the original height, and spaced approximately 38 yards apart on each side of the road.

Mr. Roles states that no particulars regarding the actual amount of light provided by each department as shown in candle-feet on the roadway were placed before the Sub-Committee, who judged the effect solely by their own observation, and, as the gas lamps were so close together, a more even illumination was naturally provided by the gas. From tests which were taken, the result of which are shown in the accompanying curves, it will be seen that the amount of light provided by the arc lamps was in all portions of the roadway greater than that provided by the gas lamps, but in the immediate vicinity of the posts the light from the arc lamps was so considerably greater than that of the gas lamps that the portion of the road midway between posts looked darker in comparison.

Mr. Roles gives several possible reasons which may have influenced the decision having gone in favour of gas, such as the yellow colour of the light of the flame arc lamps used. The general impression that the gas installation gave the better light he thinks was due to the fact that the gas lanterns were so near

Reference.

2. ,, ,, ,, Ordinary ,,
3. Gas Lamp with Three Incandescent Mantles.

TEST CURVES OF EXPERIMENTAL GAS AND ELECTRIC STREET LIGHTING.

to the road that the sources of light were very near the eyes, whereas in the case of the arc lamps they were well above the head, and only the effects of the light on the road were observed. There appear to have also been several local reasons, quite apart from economic or photometric considerations, which favoured the gas undertaking.

With regard to the comparative costs of electric and gas lighting as already given, it is interesting to know that in a recent report the Gas Manager stated that the cost of lighting in Manningham Lane was 2s. 5½d. per yard, yet when 75 three-light gas lanterns were erected in a length of street formerly lit by approximately 22 two-light lanterns, the cost of lighting was only increased to 6s. 4¾d. per yard. It is also interesting to note that the latter price per yard was stated after the Electricity Department had published the fact that their lighting by means of arc lamps would cost 6s. 5d. per yard.

Since the experiment was first started, an attempt has been made to render the illumination of the street more even by means of dioptric globes fitted to the arc lamps. This attempt has met with a very considerable amount of success, as can be seen from the two curves reproduced.

The type of lamp used is the "Excello" 16-hour, single-carbon, 8-ampere, flame arc lamp, fitted with deposit free dioptric inner globe and opalescent outer globe.

CATALOGUES AND PAMPHLETS, &c., RECEIVED

[READERS APPLYING TO ANY OF THE UNDER-MENTIONED FIRMS FOR COPIES OF THE CATALOGUES OR PAMPHLETS REFERRED TO ARE REQUESTED TO MENTION "ELECTRICAL ENGINEERING."]

BRICKS AND TILES.—A leaflet from Hamblet's Blue Brick Co., Ltd. (Piercy Brick & Tile Works, West Bromwich, Staffordshire), calls attention to some very satisfactory tests that have been made on the crushing strength of the company's vitrified blue bricks.

FACTORY SITES.—The Electricity Supply Department of the West Ham Corporation (84 Romford Road, Stratford) have, with their characteristic enterprise, issued a list of vacant factory sites and manufacturing premises in the Stratford and Silvertown districts.

PETROL AND PARAFFIN ENGINES.—A catalogue from Messrs. H. and C. Grayson, Ltd. (21 Water Street, Liverpool), gives particulars of high-speed enclosed oil engines for coupling to dynamos and pumps. These are made in two-cycle design as well as for the four-stroke cycle, and all can be adapted either for petrol or paraffin. The sizes range in the two-cycle pattern from 1 to 20 h.p., and the four-cycle engines are made from 4 h.p. upwards. The cycle of the two-stroke engines is as follows:—The upward stroke of the piston draws a charge into the crank case, where it is compressed on the next downward stroke. When the piston is nearly at the end of the down stroke, an exhaust port is uncovered in the cylinder side, permitting the exhaust to escape, and immediately afterwards the inlet port on the opposite side of the cylinder is opened, allowing the compressed charge in the crank chamber to enter the cylinder, thus driving out the exhaust gases. By means of a specially constructed piston, with baffle plate, the inlet gases are prevented from passing through the exhaust port. The gases now in the cylinder are compressed on the next upward stroke, and fired shortly before the piston reaches the top. The upward stroke, therefore, is both a compression stroke and a suction stroke for filling the crank chamber with explosive gases. The downward stroke is during its first part an explosion stroke, and during its latter an exhaust and inlet stroke.

ELECTRIC FANS.—A new leaflet from the Electrical Company gives prices and particulars of a number of patterns of electric fans of the A.E.G. manufacture.

CASE HARDENING.—A book containing a quantity of useful information regarding the practice of case hardening, annealing, &c., is being issued by Messrs. W. H. Palfreyman & Co. (17 Gorel Piazzas, Liverpool), who specialise in requirements for this purpose, and manufacture a special hydro-carbonated bone black, which enables great uniformity of hardening to be obtained. Another useful preparation supplied by the firm is Palfreyman's rust-preventer for bright metal surfaces.

DYNAMOS AND MOTORS.—A pamphlet from Messrs. T. W. Broadbent, Ltd. (Victoria Electrical Works, Huddersfield), gives particulars of a series of continuous-current dynamos and motors manufactured by this firm, as well as shunt regulators and switches. The company inform us that among their orders in hand are a 100-kw. three-phase alternator, a 12-kw. compound-wound continuous-current generator, and a large number of three-phase and continuous-current motors ranging from 25 to 1½ h.p. They have also under construction a large three-phase switchboard for lighting and power, and a continuous-current main lighting switchboard.

FITTINGS AND SHADES.—Two small but attractive booklets have been issued by Simplex Conduits, Ltd. One of these illustrates a number of typical patterns of table lamps, brackets, and other fittings, and the other calls attention to a new form of shade made of a durable translucent material giving a similar effect to stained glass, but light, cheap, and unbreakable. These artistic productions are known as "Spookie" shades.

SPEED INDICATOR.—A booklet received from Messrs. Siemens Bros. & Co., Ltd., of Caxton House, Westminster, describes an apparatus for indicating the speed of an engine or other shaft at a distance from the shaft. It is especially adapted for ships. A generator comprising a fixed armature and a rotating permanent magnet field is driven by the shaft, and the pressure is indicated on a Ferraris voltmeter provided with a scale graduated in revs. per min. The zero is in the middle, and the pointer moves to the right or left according to the direction of rotation.

FANS. A leaflet from the Wilson-Wolf Engineering Co., Ltd. (Thornton Road, Bradford), gives prices and particulars of the company's "Arctic" electric propeller fans for continuous current, which are now listed up to 72 inches in diameter. This largest size has a 1¾-h.p. motor, running at 170 r.p.m., and discharges 36,000 cu. ft. of air per minute.

MINE EXPLODERS.—A leaflet from British Insulated & Helsby Cables, Ltd. (Prescot), describes and illustrates several sizes of the Helsby magneto mine exploder, which is manufactured for both low-tension and high-tension working. A complete range of accessories, including a great variety of special shot firing cables for various conditions is also listed.

JOINT BOXES.—Among further new leaflets issued by the same firm are two dealing respectively with L.T. three-phase three-way disconnections for boxes suitable for colliery work and general use, and straight-through, non-disconnecting joint boxes for vertical or horizontal positions, and suitable for three-core low-tension wire-armoured cables.

TANTALUM LAMPS.—We have received a new list from Messrs. Siemens Brothers' Dynamo Works, Ltd., Tyssen Street, Dalston, dealing with the various types of tantalum lamps now on the market, and announcing reduction in prices. The high voltage lamps are now to be sold at the low price of 3s. 6d. in bell shaped bulbs, and 3s. 9d. in spherical bulbs. The standard bell-shaped or spherical lamps of 50-80 volts, 12 and 16 c.p., are now to be sold at 2s. each. Illustrations of a new tantalum candle-lamp, which is supplied for 24-40 volts, and in 5 and 10 c.p. sizes are also shown. We understand that the new factory at Dalston, opened some few months ago, has great facilities for the manufacture of these lamps, and that rapid progress has been made in the last few weeks.

Electric Power in South Wales.—The mains of the South Wales Electrical Power Distribution Co., connecting up Cwmbran, Pontypool, Crumlin, Newbridge, Abercarn, and Risca, have been joined to the system of mains in the Treforest district, and the supply in the parts above named, formerly obtained from the Cwmbran generating station, is now given from the Treforest power station. The new line connecting the two districts is partly overhead and partly underground. The Cwmbran power station has been shut down, but will be kept in working condition as a reserve station. A new sub-station is to be erected at Newbridge for the supply of the Celynen Collieries of the Newport Abercarn Black Vein Steam Coal Co. for haulage gear, &c. The whole of the supply in Monmouthshire is thus now taken over by the Treforest Electrical Consumers' Co., who, it will be remembered, acquired the Treforest power-house from the South Wales Co. under the scheme of reconstruction a few years ago.

British Electrical Manufactures in Japan.—The British Vice-Consul at Osaka, Japan, writes as follows concerning the trade of the district during 1908 so far as it relates to the electrical industry:—In the supply of electrical machinery, equipment, &c., there has been active competition between British, American, and German manufacturers. Until recently an American firm had practically a monopoly in the Osaka district, but latterly British and German firms have secured contracts. With the opening up of electric railways and the extension of various electric light companies, it is probable that large quantities of electrical machinery, &c., will be required during the next few years. It is impossible for British manufacturers to secure contracts for machinery, &c., unless they have an experienced representative on the spot, as a knowledge of local and personal considerations and the methods of tendering, &c., is absolutely essential.

City and Guilds of London Institute.—The annual report of the Council of the City and Guilds of London Institute records with great regret the death of Prof. W. E. Ayrton, F.R.S., in November last. Mr. T. Mather, F.R.S., who has been Prof. Ayrton's chief assistant at the Central Technical College from the first, and who has carried on the direction of the work of the department during the frequent ill-health of the Professor in recent years in a most efficient manner, has been appointed Acting Professor of the Department for the current year. Prof. Dalby has been reappointed to the office of Dean of the Central Technical College for a third session, notwithstanding that it has been the practice of recent years to limit the period during which a professor shall hold the office to two years. Several important pieces of apparatus and machinery have been added to the equipment of the laboratories, designed, and in some cases constructed, in the laboratories and workshops. The Electrical Department has received from Prof. Ayrton electrical apparatus to the value of £110, which had been presented to him by Mrs. Thomson, widow of the late Capt. Thomson, R.E. These comprise one extra high-tension three-phase transformer, 62-30,000 volts, made by Messrs. Brown, Boveri & Co.; ten specimens of different types of high-tension insulators used on the Cauvery power transmission scheme, India; and 20 E.P.S. storage cells. An investigation on the proper size of carbons for use with searchlights was carried out during the session by Mrs. Ayrton, assisted by two third-year students, and the results have been embodied in a report to the Admiralty. At the Finsbury Technical College several important additions have been made to the machinery and apparatus during the year. A new Yarrow water-tube boiler has been installed in connection with the electric lighting plant, and in the Electrical Department a useful rearrangement and extension of the equipment has been carried out. A Grassot's flux meter has been acquired for magnetic work.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published May 27th, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications. Names in italics indicate communicators of inventions from abroad.

14,942/08. **Manufacture of Tungsten Filaments.** WESTINGHOUSE METAL FILAMENT LAMP CO. (*Westinghouse Metalfaden Gluhlampen Fabrik-Ges.*), Tungsten trioxide is reduced by means of zinc at a red heat, and the product treated with a hydrochloric and nitric acid solution to remove the excess of zinc and the zinc oxide. The product is then thoroughly washed and concentrated by evaporation. The pasty mass obtained, without the addition of any binding agents, is formed into filaments. These, after being heated in a muffle furnace at about 800° C. for half an hour, are raised to a white heat in an atmosphere of hydrogen and nitrogen, by passing current through them. Two claims.

15,030/08. **Lamp Cap.** F. WILKINS. The cap of an incandescent lamp is provided with an extension-piece bent back so as to surround the cap and form a hood over the cap and holder. This prevents the access of water into the holder, and is especially adapted for lamps arranged upside down in exposed positions out of doors. For lamps to be used at an angle one or more lips or spouts are provided. Three claims, three figures.

15,346/08. **Arc Lamp Mechanism.** S. C. MOUNT and BECK FLAME LAMP, LTD. A method of mounting the carbon holders of gravity-feed flame lamps is described. The holders, which run on inclined guide rods in the usual manner, are caused to move down together by a system of links, and no central guide rod is required. The carbons feed down as the carbon resting on the refractory support is consumed. Three claims, one figure.

22,426/08. **Insulation of H.T. Switchgear.** A. E. PEYRUSSON. Instead of immersing the contacts of H.T. switches in oil, it is proposed to use tetrachloride of carbon which is a good insulator, incombustible, and contains less than eight per cent. of carbon. It is less viscous than oil, and thus allows quicker action in the case of magnetically-operated gear. Further, the small quantity of carbon liberated by the inevitable decomposition due to the arc, rises to the surface, and water also remains at the surface, owing to its high density. Its freezing point is low. To prevent the evaporation of the liquid, water, or a solution of glycerine in water is placed on top. Three claims.

23,069/08. **Supports for Metal Filaments.** BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*). In the arrangement described, the lower ends of the loops are welded to metal arms radiating from the base of the pedestal. A number of short copper wires fixed vertically on the top of the pedestal support horizontal pieces of nickel wire. Each nickel arm carries at its extremity a small loop of tungsten or molybdenum, through which the filament passes. The nickel wire acts as a spring holding the filament in tension, and can be joined to the supporting loop by winding the end round the crossed legs of the loop. The other end is welded to the copper support. The supporting loop and the nickel wire spring should have diameters slightly larger than the diameter of the filament. Four claims, two figures.

24,224/08. **Storage Battery Plates.** L. FIEDLER. The plates are formed with a number of V-shaped superposed shelves, and after the active material has been inserted, the plates are placed between dies so shaped that in forcing the dies together, the outward extending portions of the shelves are bent upwards and inwards so as to consolidate and partially enclose the material. Three claims, seven figures.

25,854/08. **Manufacture of Tungsten Filaments.** SIEMENS & HALSKE AKT.-GES. Powdered tungsten is treated chemically or electrochemically so that each particle of tungsten receives a deposit of 10 to 20 per cent. of a ductile metal such as silver or nickel. The product is pressed and rolled, and the mixture becomes so intimate that a ductile metal that can be drawn into filaments is obtained. The nickel or silver is removed by heating the finished filament in a vacuum. In a modification, the treated powder is first stamped into a tube of ductile metal, and then drawn into fine filaments, the foreign metals being removed afterwards as in the first case. Three claims.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

Arc Lamps: SHAW, 15,116/08.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: BRITISH THOMSON-HOUSTON CO., and WEDMORE [Distributing Systems] 11,979/08; SIEMENS SCHUCKERT WERKE GES. [Insulation of fine wires] 27,097/08.

Dynamos, Motors, & Transformers: MASSONE [Traction motors] 12,447/08; SCHANSCHIEFF [Construction of field magnets] 22,450/08; ROBERT BOSCH [Insulation of coils] 28,442/08.

Electrometallurgy & Electrochemistry: CUMBERLAND [Prevention of corrosion by electrochemical action in boilers] 8,068/09.

Heating & Cooking: BRITISH PROMETHEUS CO., COOPER, and SHARP [Luminous radiators] 10,760/08; ABBOTT [Cooking and heating apparatus] 12,191/08.

Incandescent Lamps: JOEL [Portable lamps] 11,106/08; KÜZEL [Manufacture of metal filaments] 1,332/09.

Storage Batteries: MONTGOMERY, YOUNG, HELLYER, and BAKER, 27,882/08.

Switchgear, Fuses, & Fittings: CLOTHIER and A. REYROLLE & Co. [Switchgear] 10,536/08; ALLGEMEINE ELEKTRICITÄTS GES. [Relay apparatus for polyphase circuits] 15,664/08; BRITISH THOMSON-HOUSTON CO., BACON, and TUPPEN [Motor-controlling switches] 15,791/08; SIEMENS BROS. DYNAMO WORKS, LTD., and NICHOLLS [Insulation of switches] 17,412/08; BAYLISS [Lampholders and sockets] 19,365/08.

Telephones & Telegraphy: FESSENDEN [Determining bearings of ships by wireless apparatus] 2,955/08; LEWIS and FARKASCH [Disinfection of telephones] 18,204/08; TABLER [Disinfection of telephones] 1,493/09; SIEMENS BROS. & CO. (*Siemens & Halske Akt. Ges.*) [Telephone exchanges] 5,904/09.

Traction: MEISTER [Automatic signalling] 10,116/08; BAXTER [Tramcar life-guards] 10,546/08; LIRONI [Trolley wheels] 11,608/08; BOULT (*Union Switch & Signal Co., U.S.A.*) [Automatic control of speed of trains] 12,178/08; MASSONE [Traction motors] 12,447/08; BUSSE [Welding rail joints] 2,750/09.

Miscellaneous: BOULT (*O. A. Miller Treeing Machine Co.*) [Electrically-heated tools] 10,521/08; HOOKHAM [Contacts] 13,215/08; HAZLETON [Casings for interrupters] 14,646/08; PAGE (*Universal Electric Welding Co.*) [Welding] 15,424/08; GHADIALI [Electric writing without ink] 16,493/08; MCNEIL [Ploughing by power] 16,753/08; BOULT (*Electric Meat Curing Co.*) [Curing process] 23,183/08; MEIROWSKY [Condensers] 26,808/08.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

GRUNWALD [Induction furnaces] 3,599/09; CUBITT [Electrically-operated switches] 7,113/09; SWEDISH NITRIC SYNDICAT [Concentrating nitric acid] 10,591/09 and 10,592/09; ALLGEMEINE ELEKTRICITÄTS-GES. [A.-C. Commutator machines] 10,665/09; SCHWERIN [Generator] 10,793/09; SOC. FRANÇAISE D'INCANDESCENCE PAR LE GAS (SYSTEME AUER) [Supports for metal filaments] 11,149/09.

Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

Arc Lamps: H. I. WOOD [Mercury vapour lamp with starting filament] 3,774/04.

Distributing Systems, Cables & Wires, Insulating Materials, &c.: G. H. NISBETT [Cables with steel or copper sheath under, and next to, the lead covering] 3,256/96; S. Z. DE FERRANTI [Cables with sector-shaped cores] 3,363/97; H. H. LAKE (*J. S. Wilson*) [Flexible wiring conduit of non-metallic materials] 3,212/04.

Dynamos, Motors, & Transformers: B. G. LAMME [Regulation of D.C. voltage of rotary-converters by tappings on the transformer] 14,294/98; BRITISH THOMSON HOUSTON CO. (*General Electric Co., U.S.A.*) [Single-phase motor starting as repulsion, running as induction motor] 3,589/04; SIEMENS SCHUCKERT WERKE [Induction-motor windings for variable number of poles] 27,702/04.

Electric Ignition: H. C. BRASIER [Contact-breaking mechanism] 14,205/02; R. HENNIG, 3,660/04.

Switchgear, Fuses, & Fittings: R. HOPFELT [Carbon-powder resistances for motor-starters] 3,336/02; W. KINGSLAND [Switch] 3,547/04.

Telephony & Telegraphy: E. DUCRETET [Double-secondary transformer for wireless telegraphy and telephony] 3,244/04; J. E. KINGSBURY (*Western Electric Co., U.S.A.*) [Telephone receivers with diaphragms in tension] 3,431/04; J. S. STONE [Tuning in wireless telegraphy] 28,826/04, and [Bolometer receiver] 28,827/04.

Traction: J. DEVONSHIRE (*W. B. Potter*) [Traction motor controllers with additional stops for high speeds] 3,092/96; H. A. FORBES [Prevention of rail creeping] 3,098/01; W. E. OAKLEY [Fused copper rail-bonds] 3,167/03; A. RICHARDSON and W. H. ALLEN [Trolley-wire hanger with two-part clip] 3,226/03.

Miscellaneous: W. G. WILSON and WILSON & PILCHER [Trembler contact] 3,256/04; T. H. MCQUOWN [Speed indicator] 3,503/04; W. REUTER [Lifting magnets] 3,737/04.

CLASSIFIED INDEX TO ADVERTISERS IN "ELECTRICAL ENGINEERING"

One Free Entry is given to every Advertiser. Entries under additional headings, 6d. per insertion.

ACCESSORIES (Electric Light) & General Supplies.
Lundberg (A. P.) & Sons, Liverpool Road, London, N.
Simplex Conduits, Ltd., 113 to 117, Charing Cross Road, W.C.

ACCUMULATORS.
Chloride Electrical Storage Co., Ltd., Clifton Junction, Manchester.
D.P. Battery Co., Ltd., Bakewell, Derbyshire.
Hart Accumulator Co., Ltd., Marshgate Lane, Stratford.
Tudor Accumulator Co., Ltd., 119, Victoria Street, London, S.W.

ARC LAMP GEAR. London Electric Firm, Croydon.

ARC LAMPS.
Arc Lamps, Ltd., Sphere Engineering Works, St. Albans.
Electric & Ordnance Accessories Co., Ltd., Cheston Road, Aston.
Foster Arc Lamp and Engineering Co., Ltd., Wimbledon, S.W.
Jandus Arc Lamp and Electric Co., Ltd., Hartham Works, Holloway.
Oliver Arc Lamp, Ltd., Cambridge Place, Burrage Rd., Woolwich.
Reason Manufacturing Co., Ltd., Lewes Road, Brighton.

AUCTIONEERS AND VALUERS.
Wheatley Kirk, Price & Co., 46, Watling Street, London, E.C.

BELTING. E. J. Cooke, Parsonage, Manchester.

CABLES.
Aubert, Grenier & Co., 68a, Lincoln's Inn Fields, London, W.C. and at Cossonay-gare, Switzerland.
British Insulated and Helsby Cables, Ltd., Prescot, Lancs.
Callender's Cable and Construction Co., Ltd., Hamilton House, Victoria Embankment, E.C.
Connolly Bros., Ltd., Blackley, Manchester.
Simplex Conduits, Ltd., 113 to 117, Charing Cross Road, W.C.
Union Cable Co., Ltd., 27, Eagle Wharf Road, London, N.
Western Electric Co., Norfolk House, Victoria Embankment, London, W.C.

CATALOGUES & PROCESS ENGRAVING.
John Swain & Son, Ltd., 58, Farringdon Street, London, E.C.

CORRESPONDENCE INSTRUCTION.
International Correspondence Schools, Kingsway, London, W.C.

DRAWING INSTRUMENTS, &c.
A. G. Thornton, Ltd., 62, King Street West, Manchester.

DUCTS.
Key Engineering Co., Ltd., 4, Queen Victoria Street, E.C.

DYNAMOS, see MOTORS & DYNAMOS.

ECONOMISERS.
E. Green & Son, Ltd., Wakefield and Manchester.

ENAMEL (Anti-Sulphuric).
Griffiths Bros. & Co., Mack's Road, Bermondsey, S.E.

FANS.
British Westinghouse Electric and Mfg. Co., Ltd., Trafford Park, Manchester.
Davidson & Co., Ltd., Sirocco Engineering Works, Belfast.
Simplex Conduits, Ltd., 113 to 117, Charing Cross Rd., W.C.

FLEXIBLE METALLIC TUBING.
United Flexible Metallic Tubing Co., Ltd., 112, Queen Victoria Street, London, E.C.

FUSE TONGS.
Fritz Luling, Kusnacht, Zurich, Switzerland.

GAS AND OIL ENGINES.
Crossley Bros., Ltd., Openshaw, Manchester.
Mather & Platt, Salford Iron Works, Manchester

INSTRUMENTS (Electrical).
Electrical Standardizing and Testing Institution, 62—70, Southampton Row, London, W.C.
Elliott Bros., Century Works, Lewisham, S.E.
Everett, Edgcumbe & Co., Ltd., 87, Victoria Street, S.W.
Evershed & Vignoles, Ltd., Acton Lane Works, Chiswick, S.W.
India Rubber, Gutta Percha, & Telegraph Works Co., Ltd., 106, Cannon Street, E.C. ; Silvertown, E.
Nalder Bros. & Thompson, Ltd., 34, Queen Street, London, E.C.

"Electrical Engineering," although the Cheapest Electrical Paper (Price **1d.** *weekly), contains the Most Useful and Practical Articles, the Best Illustrations, and the Latest News. It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.*

SUMMARY

An illustrated description is given of some large gas engines just completed in this country for export to India. (Page 523.)

A push electric lift control system is described on page 523.

Mr. H. Mozley (General Manager, Burnley Corporation Tramways) has called our attention to the results of his experience that cast-iron blocks are more satisfactory for track brakes than wood blocks, contrary to the conclusions expressed by Mr. H. M. Sayers in a recent article in Electrical Engineering. (Page 525.)

Under "Electrometallurgy and Electrochemistry" an account is given of the features of the recent International Congress of Applied Chemistry of electrical interest. (Page 526.)

Among the Papers read before the recent meeting of the Institution of Mining Engineers in London was one by Mr. R. Nelson (H.M. Electrical Inspector of Mines) on "Electricity in Coal Mines," in which he reviewed the conditions of underground installations from the point of view of safety, and made many important recommendations in matters of detail. (Page 527.)

A communication from Mr. W. P. Durtnall relates to some remarks on electric propulsion of ships which he made in a discussion some time ago. (Page 528.)

We are able to publish some further photometric curves relating to the experimental gas and electric street lighting in Bradford. (Page 528.)

The conversion of the central portion of the Adelaide tramway system to electric running is nearing completion. (Page 530.)

In a lecture before the Royal Institution, on Thursday, Prof. Dalby dealt with the relative merits of steam and electric traction. There was, he said, little difference between the actual efficiency of the two methods, as in each case about 4 per cent. of the energy of combustion of the coal was utilised for traction. For long non-stop runs steam was most satisfactory. The travelling public would not pay for high speeds, but, if they wanted them, electric traction would have to be employed. For frequently-stopping trains with high schedule speeds, electric traction was inevitable. (Page 530.)

At the last meeting of the Newcastle Section of the

Digitized by Google

Institution of Electrical Engineers, Mr. A. S. M. Sörensen read a Paper on the wireless telegraph station at Cullercoats. The installation comprises a "spark" apparatus, with de Forest electrolytic receiver, as well as the more recently installed complete Poulsen "arc" equipment, with which, by a photographic printing arrangement, messages have been received from Lyngby, in Denmark, at the rate of 100 words per minute. A brief discussion ensued. (Page 531.)

WE publish this week a description, with drawings, of the two new cooling towers recently erected at the Stuart Street Electricity Works of the Manchester Corporation. (Page 532.)

A NEW wiring system is described on page 534.

IT has been remarked that the coming into operation of the new Miners' Eight Hours Act will give a considerable impetus to the adoption of electric underground haulage gears. (Page 534.)

THE following books are reviewed in this issue:—"Hydro-Electric Practice," by H. A. E. C. Von Shon; "A Pocket Book of Electrical Rules and Tables," by the late J. Monro and A. Jamieson, 19th edition.

CONSIDERABLE extensions are to be made to the power-house at Sydney, which now has an annual output of 9,000,000 units. Major Cardew, who has just reported on the undertaking, recommends the installation of 4,000-kw. turbo-alternators and the erection of a coal-conveying plant. Troubles have been experienced with the condenser tubes, and different methods of preventing corrosion due to electrolytic action are being tried. (Page 535.)

A NEW bell push is described on page 536.

APPLICATION was made a few months ago for the revocation of a patent granted to L. Scholvien for some methods of supporting metal filaments, including one in which the filament passed through hooks fixed to the walls of the bulb. The objects of the different arrangements are to improve the distribution of light and to prevent short-circuiting of portions of the filament. After examining the evidence filed by the patentee in answer, the application has been abandoned. (Page 536.)

A PROPOSAL has been made for the construction of a tube railway under Sydney Harbour.—Vibration from the electricity works at Calcutta is being complained of by occupiers of adjacent property.—A loss of £5,416 has been incurred upon the Bournemouth Corporation tramways last year.—A net profit of £2,914 is shown by the Bury electricity department last year.—The adoption of the trackless trolley system is recommended by a sub-committee of the Leeds Tramways Committee.—The sum of £17,250 is transferred to rates by the Nottingham Electricity Department, and £15,400 by the Tramways Department. (Page 537.)

THE Belfast Corporation require switchboard panels; a 1,000 gallon water softening plant is required at Eastbourne; a 3,000 gallon plant at Eccles, and cables, &c., at Devonport; Local Government Board inquiries will shortly be held as follows: Blackburn, £18,000; Bolton, £7,000; Darlington, £3,900; Leyton, £2,458; Maidenhead, £3,500; Salford, £3,000. (Page 538.)

THE Newcastle-on-Tyne Electric Supply Co. are inviting subscriptions for £687,500 consolidated first mortgage debenture stock. (Page 540.)

AT the Royal Institution, on Friday, Prof. J. A. Fleming delivered a lecture on "Recent Researches in Wireless Telegraphy." He pointed out that there was very little absorption of the energy of the electric waves when they were travelling over sea water, which was a good conductor; but that over dry soil or rocks the waves penetrated deep, and there was much absorption. The multiple-gap transmitter of the Telefunken Co. for generating continuous oscillations was described, and the conditions for successful tuning were discussed. (Page 541.)

IN some Papers recently read before the Physical Society, a new bifilar vibration galvanometer, designed by Mr. W. Duddell, was described, and an account was given of some researches on the effect of temperature on the hysteresis loss in iron in a rotating field. (Page 543.)

THE telephone engineers recently put on trial at Antwerp for stealing trade secrets have been acquitted. (Page 543.)

A PATENT specification by G. Hookham, describing a method of ensuring an intimate contact between the mercury and the metal armature of mercury motor meters, was published by the Patent Office on Thursday. Among the others published was one for an overload or no-voltage relay for polyphase circuits, comprising a wound ring field system and an armature, both with polar projections, by the Allgemeine Elektricitäts Ges., and another by Siemens Bros.' Dynamo Works for a method of mounting the contact studs of motor starters, &c. The studs are bolted to a micanite plate, which is fixed over slots in the metal base. A patent referring to the curing of meat by electricity is also abstracted. The opposition to the grant of patents to C. C. Garrard and Ferranti, Ltd., for a balanced system of protection for cables, in which no pilot wires are used, and to Siemens and Halske Akt.-Ges., for the manufacture of tungsten filaments from nickel-tungsten compounds, has been unsuccessful. Among the patents expiring during the current week is one by H. A. Taylor and J. A. Dearlove for a repeating mechanism for submarine telegraphy. Two patents by the Western Electric Co. relating to the use of lamps as indicators in telephone exchanges also expire this week. (Page 544.)

MR. F. B. O. HAWES, the new secretary of the National Electrical Manufacturers' Association, has sent us an advance copy of a new pamphlet, setting forth clearly the objects of the Association, and mentioning the directions in which its activities have been beneficial to the interests of electrical manufacturers. Put very briefly, the work of the Association is to watch the interests of electrical manufacturers in every direction, and to enable joint action to be taken with regard to the abatement or removal of any hardships or abuses from which the industry may suffer and in the settlement of trade disputes. It has been successful in obtaining an improvement in certain railway rates by rectifying the classification of electrical apparatus; the alteration of a number of unfair clauses in municipal and other specifications has been largely due to the Association's representations; it has saved its members considerable sums in fire insurance policies through the activity of its expert; and it has promoted the two thoroughly successful electrical exhibitions in 1905 and 1908, from which the industry has greatly benefited. As in the case of the Society of Motor Manufacturers and Traders, a substantial rebate is received by members of the Association off the ordinary rates for space at these exhibitions. These are only some of the directions in which the National Electrical Manufacturers' Association has done good work. At present, although the membership is representative of the various branches of the electrical industry and some of the largest firms are members, there are many manufacturers who have not yet joined the ranks of the Association, and whom we can confidently recommend to put themselves in communication with Mr. Hawes, the Secretary.

For "Arrangements for the Week," see p. 536.

TWO LARGE BRITISH-MADE GAS ENGINES

THE East Indian Railway Co. some time ago decided to utilise, by means of gas engines, the waste gases from their coking ovens at their Giridih Collieries, and on the recommendation of their Consulting Engineers, Messrs. Rendel and Robertson, recently placed an order for machinery for this purpose in the hands of Messrs. Mather and Platt, of Manchester. The plant has now been completed, and will shortly be shipped, and a view of the engines erected in the works for testing is reproduced in the accompanying figure.

There are two engines running at 167 r.p.m., each coupled directly to a 3-phase alternator wound for 2,300 volts 50 cycles. Each alternator has a normal output of 200 k.v.a. on a power factor of 0·75, but the sets are also capable of 20 per cent. overload for two hours. The engines are of the Körting double-acting two cycle pattern, and embody Messrs. Mather and Platt's improvements and simplification of this form of engine. They are intended to run in parallel, and are particularly suitable for this, as owing to an impulse being produced at every stroke the turning is extremely regular, and the cyclic irregularity does not exceed $\frac{1}{200}$. Each engine has two cylinders, side by side, with cranks at 90° apart, thus 4 impulses will be given to the shaft per revolution.

The construction is remarkably simple, and as the flywheel is placed between the cylinders, with the field-magnets of the alternator mounted on the flywheel rim, the whole arrangement is compact, well-balanced, and easily accessible. Duplicate sparking-plugs and ignition gear is provided for each end of cylinders. The alternators are coil wound, of the makers' standard construction, high-class machines in every respect, and the exciters are driven by "Morse" chains. To start the engines compressed air will be used, with a compressor of special type, driven by coke-oven gas. It has two cylinders—one for gas and the other for air—and delivers the air to reservoirs at 150 lb. pressure per sq. in.

TWO LARGE GAS ENGINES BUILT BY MESSRS. MATHER AND PLATT FOR THE EAST INDIAN RAILWAY.

We are informed that the order was placed with Messrs. Mather and Platt after competition with all the gas-engine makers of this and other countries, the double-acting two-cycle type of engine being considered the best suitable for the extreme regularity of turning necessary for parallel working of alternators, while the simplicity of construction and reliability of operation of this type were also, doubtless, factors in influencing the Consulting Engineers' decision in their favour.

A PUSH-BUTTON ELECTRIC LIFT CONTROL SYSTEM

THE advantages of push-button control systems for electric lifts are becoming more and more widely appreciated, and the patented system, which has been developed by the Felten & Guilleaume-Lahmeyerwerke Co., of Frankfort, is of considerable interest on account both of its ingenuity and its simplicity. There are various modifications of the arrangement, according as the lift is intended to be *controlled entirely* from the landings as in kitchen and service lifts, to be *called* only from the landings and be sent to the desired destination only from the car with or without an extra push-button to return the car to the ground floor when done with, or to be operated from the car as well as from all the landings. The last-mentioned system is, however, only suitable for special cases, but it is here chosen for description, as being the most suitable for explaining the principles of push-button control.

Fig. 1 shows a diagram of connections. A group of push-buttons, comprising as many as there are landings, is fitted in each floor and in the car. In order to prevent the lift from being operated whilst any landing-gate or car door is open, safety contacts are fitted to all doors and gates. These permit the lift to be started only when all the gates and doors are shut. The floor switches (Fig. 3), one of which is fitted at each landing, are operated by special shaped guides, shown in Fig. 2, attached to the car. By this means the car is stopped at any desired floor in the manner described below. In addition to the floor switches, a "limit switch" is fitted at the bottom of the lift well, which serves both as a safety device against accidental failure of the control, and also for cutting off the current from the motor when the car has reached the extreme end of its travel in either direction, so as to prevent overrunning. A "slack cable safety switch" is also fitted, which interrupts the control circuit if either the car or balance weight should meet with any obstruction when ascending or descending. The leads in the car are connected to those in the lift well by means of flexible cable, which is composed of a suitable number of strands. The slack cable safety switch is also used as a floor contact in the car for interrupting the control outside while the passenger is in the car.

In order to explain the working of the system, let us consider the case of a three-floor lift as indicated in Fig. 1. Assume that

D

Digitized by Google

the car is at the second floor, and that it is to be despatched by the passenger to the third floor. The button inside the car marked with the required destination is pressed. This closes the following circuit, from the positive pole of the main switch-board to the car by a cable through all the door contacts *O*, through the depressed button in the car, through the relay board *D*, through the floor switch *N*, through the common return wire of the floor switch and the resistance *K* to the negative pole. The winding of the relay is therefore energised, by which means its magnet becomes excited and attracts a movable armature. When the armature is excited, the relay is no longer energised by the push-button, but directly by an auxiliary contact of the relay. It is therefore unnecessary to continue pressing the push-button, as the relay magnet serves to close the circuit until the car reaches its destination. The resistance *K*, which is connected in series with the relay in circuit, is further rated in such a manner that whilst any one relay is in circuit a second relay cannot possibly become sufficiently energised, even if another push-button were to be pressed down; thus, as soon as any one circuit has been closed, all other push-buttons are rendered inoperative, and only the relay first put into circuit attracts its armature. If two push-buttons were accidentally pressed down simultaneously, then both their corresponding relays would remain unexcited. The control will only commence to operate when one push-button alone is pressed down.

The attraction of the armature of the relay further causes that magnet winding of the reversing switch *C*, which is intended for ascent, to be energised, and put the reversing switch into circuit for the upward motion of the car. By this means the brake-lifting magnet is also energised so that the brake connected with the magnets is lifted and the motor runs free. In addition to this, the magnet winding of the starter is energised, its armature attracted, and the motor started as the starting resistances are cut out step by step. The motor now continues to run until the car has arrived at the desired destination, *i.e.*, at the third floor, in which position the tappet fitted to the bottom of the car switches out the floor switch *N*, and in this way interrupts the circuit to the relay; the magnet of the reversing switch, being now no longer excited, opens the circuit; at the same time the brake magnet comes into action and brings the motor to rest immediately. The push-buttons in the cabin and at the landings have a common return wire, which is led through the emergency "stop" button in the car and through all the door contacts—that is to say, they are all arranged in parallel, so that if at any time the number of stopping-places should be increased, no special alterations to the control would become necessary. When the car is required to go in the opposite direction, the control operates in a similar way as already explained for the journey from the second to the third floor. As the emergency "stop" buttons in the car and all the door contacts are connected by one and the same lead, the common lead-carrying current to all relays is always interrupted when the circuit is to be broken.

A floor switch and a relay for descent and ascent is fitted at the top and bottom floors respectively, and a floor switch and two relays for descent and ascent to each of the intermediate floors. Control takes place automatically in the following manner: If, for example, the ascending car passes the second floor, then it changes over the floor switch by means of the tappet fitted to the bottom of the car into such a position that the current, which formerly flowed through the relay intended for ascent, now flows through the relay intended for descent. Consequently, all push-buttons now pressed on the floor the

lift is in, or any of the floors below, give the lift a downward motion when next started. In like manner, when the lift descends, it automatically reverses the floor switches again, and thus prepares the circuit once more for ascent. With this arrangement it is therefore unnecessary to fit two special push-buttons, namely, for second floor "up," and second floor "down."

Various types of starters can be used; in one, a number of electromagnets connected in series cut out the resistance steps according to the voltage in the motor armature. Each magnet, by adjustment of its stroke, is set to any desired voltage. In some of the larger starters, a solenoid-operated step-by-step arrangement is used.

Instead of being separate, the various single pieces of apparatus, such as floor relays, switches, reversing switches, and starters with their respective resistances can be combined to form one piece of apparatus with the "commutator device" (see Figs. 4 and 5).

This commutator device consists of a spindle along which a travelling-nut moves. The travelling-nut reproduces the motion of the car on a small scale, and mechanically operates the relays arranged parallel to the spindle. The distance between these corresponds to the distance between the stopping-places. In all other respects this control is identical with the arrangement with the floor switches fitted in the lift well. The erection of the apparatus is, however, very much simplified. A disadvantage of this device as compared with the use of floor switches is that, with variable loads, the stop here is not quite so accurate. The system is, however, suitable for small goods' hoists, service and kitchen lifts, &c. The ordinary push-button control, with the floor switches fitted in the lift well, is to be given the preference for lifts which are intended for heavy loads and lifts by which an accurate stopping is required at varying loads.

Very little modification of the apparatus described above is required for lifts operated by alternating currents, with the exception of some of the minor apparatus. The push-buttons of the push-button register, the door contacts, floor switches, limit switch, and relays are all connected to one phase, so that the push-button circuit is identical for both three-phase and continuous-current control. The only special three-phase apparatus which is used is the reversing switch and the brake magnet. Further, for lifts with three-phase control, an automatic starter with centrifugal regulator, driven by means of a belt directly from the motor, is used in place of the starter for continuous-current control. For lifts for operation with single-phase alternating current, the firm exclusively use special single-phase commutator motors capable of developing about 2½ times their normal torque, and not requiring any special starting device.

Westinghouse Meter.—The Board of Trade have approved the Westinghouse single-phase meter, No. B116.660, and also the means provided for fixing same.

Electric Traction on North-Eastern Railway.—It is stated that the North-Eastern Railway Co. have decided to convert their lines from Newcastle to South Shields, and from Newcastle to Sunderland, to electric traction.

National Trades Exhibition, Birmingham.—At this exhibition, which was held in the Bingley Hall, there were several exhibits of an electrical character. Among these, Callenders Cable & Construction Co. made a very good show with samples of cables of every size and description. A model of a pit shaft was shown to demonstrate the various methods employed in supporting the lighting and power mains in mines. A feeder pillar with pole rising from the centre, which is used for the control of overhead transmission lines was also exhibited, and special joint boxes for mining work were well represented. The British Westinghouse Electrical & Manufacturing Co. showed motors and starters both for alternating and direct current. One motor was dismantled in order to make the method of construction perfectly evident. The stall was brilliantly illuminated by means of Westinghouse tungsten lamps. A three-phase 5,000- to 440-volt oil-cooled transformer was also on view. The British Electric Transformer Co. showed one of their well-known three-phase oil-cooled transformers for 100 kw. and also an air-cooled transformer of the same size. Messrs. Ferranti, Ltd., displayed their well-known house service meters for both alternating and direct current, and a large selection of instruments of the switchboard and portable types, such as power factor indicators, indicating wattmeters, leakage indicators, and frequency indicators. They also showed samples of their direct-current starters without wire coils. Messrs. Simplex Conduits, Ltd., exemplified their system of conduit and also showed samples of their cooking utensils, electric signs, fans, radiators, and metal filament lamps. Other exhibits were made by Messrs. Eckstein, Heap & Co., the Walsall Electrical Co., who showed an "Aster" paraffin engine direct coupled to a dynamo and supplying current at 50 volts. The City of Birmingham Electric Supply Department made no exhibit this year, but had an inquiry office, where information was given to consumers or others.

WOOD v. CAST IRON FOR TRACK BRAKE SHOES

OUR attention has been called to this subject by Mr. H. Mozley, general manager, Burnley Corporation Tramways, in view of the conclusions expressed in an article in ELECTRICAL ENGINEERING (April 1st, page 303), by Mr. H. M. Sayers. It will be remembered that in this article Mr. Sayers compared and discussed the tests on track brake blocks of different materials recorded in the reports of the Committees on Brakes of the Light Railways and Tramways Association and the Municipal Tramways Association, and came to the conclusion that, while the question needed further investigation in certain indicated directions, practical experience and the test results, taken together, supported the general use of wooden blocks for the control of speed on steep gradients.

Mr. Mozley, however, takes the opposite view, and is strongly in favour of cast iron brake shoes, and claims that the results of his own experience on the Burnley Corporation Tramways show that cast iron is greatly superior to wood for the purpose. In this connection, the following extract from his report on the Burnley Tramways for the year ended March 31st, 1909, is of interest:—

"The Municipal Tramways Association appointed a Committee two years ago to inquire into the subject of brakes, and I was appointed, with your consent, on that Committee. The conclusions of the Committee have been arrived at and published, and a copy of the report has been forwarded to you. The recommendations are now the subject of consultation with the Board of Trade, who will no doubt act upon them, but it is worth while placing on record now that the adoption of cast iron for track brake shoes instead of wood first emanated from Burnley. Burnley Corporation Tramways Committee were the first in this country to use cast iron for track shoes, and the discovery that cast iron and not wood was the proper material was first made on the electric locomotive built in our own works in 1903."

The matter was also dealt with at some length by Mr. Mozley in a Paper on "Car Brakes," which he read before the Conference of the Municipal Tramways Association at Leeds in September, 1906, wherein he described the exacting conditions of the service at Burnley from the brake point of view owing to steep hills and heavy four-motor cars used, and the experiments which had led up to the design of a special mechanical track brake. In the Paper he wrote:—

"This brake was erected on a locomotive we were building at the time, and its performances were so satisfactory that it was resolved to adopt it for the Manchester road cars, and here I may say, for your information, that during the trials it was found that it would be unsafe to use wood for the slippers, and that soft grey cast iron was the only suitable and safe material."

The Paper concluded with the following statement:

"The only form of brakes which will safely control a car on gradients greater than 1 in 14 or 15, are:—(*a*) Hand brake with adequate leverage actuating cast-iron blocks on the wheels; (*b*) mechanical track brake with adequate leverage provided with cast-iron slippers; (*c*) rheostatic brake for emergencies only."

Mr. Mozley thinks that, in the light of the experiences recorded above and other results published from time to time in the official Reports of the Municipal Tramways Association, there is little excuse for the belief that the old-fashioned wood block is still unexcelled.

National Electrical Manufacturers' Association.—A committee meeting of this Association will be held at Balfour House, Finsbury Pavement, London, on Tuesday, June 15th inst., at 2.30 p.m.

Electric Smelting.—H.M. Consul at San Francisco announces that a large electric smelter has recently been put into operation, with satisfactory results, at Heroult, near Redding, California. The success of this furnace is regarded as opening up a possibility for the establishment of large iron works on the Pacific Coast, where there is an abundant supply of electrical energy.

ELECTROMETALLURGY AND ELECTRO-CHEMISTRY.

The International Congress of Applied Chemistry

A LARGE number of Papers of interest in connection with electrochemistry and electrometallurgy were read before the International Congress of Applied Chemistry, which was opened on May 27th by the Prince of Wales at the Royal Albert Hall. The Congress has been attended by over 4,000 members, and altogether something like 1,000 Papers have been read in the seventeen sections. That devoted to electrochemical matters dealt with 115 separate communications.

One of the most interesting of the Papers read before the Congress was that of Prof. Bernthsen, director of the Badische Anilin- und Sodafabrik, on the fixation of atmospheric nitrogen. The arc furnace developed by the Badische Anilin- und Sodafabrik was fully described and illustrated on p. 515 of ELECTRICAL ENGINEERING for June 3rd, but the following additional items from Prof. A. Bernthsen's Paper are of interest. A 1,000-h.p. furnace, which has an arc about eight yards long, requires some 40,000 cubic feet of air per hour. The outcoming gas contains 2 per cent. of nitric oxide, which is said to be nearly twice as high a concentration as obtained in the Birkeland-Eyde furnace; the theoretically maximum value is 5 per cent. As we have already stated, the Badische Anilin-und Sodafabrik and two allied German firms have combined with the Norsk Hydro-Electrisk-Kvaelstof Aktieselskap (Norwegian Hydro-Electric Nitrogen Co.), which uses the Birkeland-Eyde furnaces. Two new companies have been founded by this combination, one to develop Norwegian water power, and the other, the Norsk Salpeterverker (Norwegian Nitrate Works, Ltd.), to carry on the manufacture of nitrates. Prof. Bernthsen further states that, including the works under construction and the proposed 50,000 h.p. works near Burghausen in Bavaria, the annual output of nitrate of lime may reach 100,000 tons in a few years. Prof. Bernthsen showed an experimental arc furnace comprising a glass tube containing a copper spiral fastened against the inside wall. Within about half a minute two large globes connected with the arc tube were filled with brown fumes of oxides of nitrogen. Prof. Birkeland then briefly described the chief features of the Birkeland-Eyde process. (See ELECTRICAL ENGINEERING of June 3rd, p. 516). Dr. N. Caro described the cyanamide process, and claimed that it was the cheapest method for fixing atmospheric nitrogen. It is easy to obtain ammonia directly from cyanamide, and a number of other chemical products can be obtained from it; furthermore, it can be directly employed as a fertiliser.

Mr. E. R. Taylor, of America, read an extremely interesting Paper on the important matter of the international conservation of natural sources of energy. He referred in the main to the conservation of water power, and deplored the waste of energy which goes on all over the world. Incidentally, he said that the nations of the world ought to be grateful to Great Britain for the magnificent barrage schemes which had been carried out in Egypt.

Papers of great interest were read by Prof. Donnan on the Findlay electrolytic alkali cell, and by Dr. Bakeland on "Three Years' Practice with the Townsend Cell." These are both diaphragm cells, and therefore it was of interest to compare the relative efficiencies. The Townsend cell has been worked on a much larger scale than the Findlay, and shows, even with large units of 2,500 amperes, an efficiency of over 95 per cent.

The sitting on Friday, May 28th, was mainly devoted to Papers in connection with electric furnace methods. Mr. J. A. I. FitzGerald contributed an interesting communication in which he abstracted some Papers which had been recently contributed to the American Electrochemical Society on the subject of the electrometallurgy of iron and steel.

Among these was a note by P. McBennie describing conditions in California as regards the manufacture of pig iron, which there costs from 23 to 25 dollars per ton, and where conditions are unfavourable for blast furnaces on account of the high price of coke. These conditions have led to experiments by the Noble Electric Steel Co., from which it is estimated that pig iron may be produced electrically for 15 dollars per ton. The same subject was taken up by Mr. Dorsey A. Lyon, the manager of the Noble Electric Steel Co., who gave a brief account of the history of the experimental plant. After some preliminary experiments in 1907 with a three-phase 1,500 kw. Heroult furnace, Mr. Lyon worked with a small 160 kw. furnace of a different type, from which he designed the 1,500 kw. furnace, with which experiments are now in progress. In this furnace the ore and limestone are fed into a receptacle in which they are heated by the products of combustion coming from the furnace chamber. A scale car runs upon a circular track at the top of the stack, and alternately receives a charge of ore and limestone from the pre-heater, and a charge of carbon from the hopper, the mixture then being emptied into the body of the furnace. Above the charge, small openings with suitable valves admit air, so as to burn the carbon monoxide gas coming from the charge. The six electrodes are arranged equi-distantly round the furnace. Prof. I. W. Richards, in another Paper, pointed out the difficulty in determining the proper amount of carbon to put in the charge, owing to the uncertainty as to the amount of CO that is formed. He recommended a furnace provided with tuyeres in the crucible, and means for regulating the supply of air so as to burn out any excess of carbon present, and also suggested super-heating of the blast by electrical means.

The remaining Papers were mainly devoted to the construction of various forms of steel furnaces. Particulars of the Stassano arc furnace, which was one of those described, have often been given in the technical press. W. C. A. Keller considered particularly the type which he distinguishes as having a "compound conducting hearth." The bottom of this furnace consists of a metallic plate, in which there are a number of iron bars about one inch in diameter, placed vertically about one inch apart. The spaces between the rods are filled with magnesia. When cold the magnesia is a non-conductor, but when hot it carries current as well as the bars. The other terminal of the furnace consists of vertical electrodes carried on swinging arms. Mr. Keller has also constructed and run furnaces in which the vertical electrodes are connected in series and without the conducting hearth, but claims that the conducting hearth has the advantages of causing the current to pass through the whole body of the metal, of ease of starting up with a cold charge, and of lessened destructive action on the roof. On the other hand the furnace with the electrodes in series has the advantage that for the same rate of generation of energy only one half the current is required, and consequently a high-power factor is easily attained. When charging with hot metal the energy required per ton is 275 kw. hours, and the consumption of the electrodes is 25 lbs. per ton. The Girod furnace has a conducting hearth, but the method of construction is different from that used by Keller. Electrodes of like polarity are suspended above the bath, while the other terminal consists of a number of pieces of soft steel buried in the refractory material of the hearth at its periphery. The upper ends of these pieces of steel fuse to a certain depth, which, however, is small, because of water-cooling devices. The fusion and refining of a cold charge requires from 900 to 700 kw. hours per ton, while the electrode consumption may be from 29 to 40 lb. per ton. Furnace linings need repair after about 100 heats, but the cover lasts only 40 to 50 heats. In France the cost of lining in large furnaces amounts to 4 to 5 francs per ton of steel. Mr. Robert Turnbull described the 16-ton Heroult furnace of the U.S. Steel Corporation at Chicago. This is supplied with metal from a Bessemer converter, and has a capacity of 16 heats a day, or 240 tons of steel. The electrodes used are 2 ft. in diameter and 10 ft. long, weighing 3,200 lbs. It is estimated that the consumption of energy will amount to 100 kw. hours per ton, and the electrode consumption to about 15 lb. per ton. In the Gin furnace the charge is heated by means of electrodes in series working in two reservoirs connected by a narrow channel, which forms the secondary of a transformer. Dr. F. A. Kjellin gave a full description of the induction furnace. In the Röchling--Rodenhauser furnace there is a secondary circuit round each leg of the magnetic circuit, each of these circuits entering a central bath. The metal is heated, not only by the current induced in these circuits, but also by a current supplied from electrodes embedded in the lining. The current of these electrodes is provided by a secondary winding on the magnetic circuit. A much better power factor can thus be obtained than in the simple induction type.

The Illuminating Engineering Society.—It will be recalled that, at an inaugural dinner held on February 9th of this year, it was decided to form an Illuminating Engineering Society, having for its object the study of the science and art of illumination in this country. An Executive Committee was appointed on this occasion to consider the drafting of the constitution of the Society, &c., and this Committee has now reported at a meeting of the supporters of the Society, held at St. Bride Foundation Institute, Bride Lane, London, E.C., on May 25th, Mr. Chas. Hastings being in the chair. The constitution and by-laws drafted by the Committee were formally ratified by those present, and the Executive Committee forming the nucleus of the first Council of the Society, were re-appointed with the power of adding to their numbers as might be expedient, in order that they might proceed with the affairs of the Society during the summer vacation. It was also decided that this Committee should approach a number of gentlemen, the names of whom were submitted to and approved by the meeting, with a view to their being invited to act as officers or on the Council of the Society. It was also agreed that the Council should be free to elect as members any who intimated their desire to become members of the Society, and were duly proposed and seconded in the prescribed manner, without the formality of ballot, up to the beginning of the first session of the Society. Anyone interested in the objects of the Society, and desiring to become a member is invited to communicate with the Hon. Secretary, Mr. L. Gaster, 52 Victoria Street, London, S.W.

ELECTRICITY IN COAL MINES

AMONG the Papers read at the annual meeting of the Institution of Mining Engineers, held in London recently, was one by Mr. Robert Nelson (H.M. Electrical Inspector of Mines), on the practical application of electricity to coal-mining, regarding the subject from the point of view of safety.

The dangers of electricity in its application to coal-mining work underground (and all subsequent remarks have application only to plant underground, not to plant on the surface) are two in number, namely :—Danger of shock to persons, owing to contact with "live" metal, and danger through the ignition of explosive gas, coal-dust, or other combustible material, by an electric spark.

In order to guard against danger from shock all "live" conductors should be completely surrounded by some insulating medium, and it is further desirable, in order to provide against failure of this insulating covering, that it in turn should be enclosed in a metallic sheath which is permanently and effectively connected to earth. Arrangements should also be made so that any leakage of current to the earthed metallic sheath will automatically secure that the faulty circuit or apparatus is immediately cut off from the supply.

When an electrical circuit is made or interrupted, a spark ensues, and if this spark should be produced in a combustible mixture of gas or coal-dust, all the elements necessary for an explosion are present. Modern opinion, Mr. Nelson said, seemed to favour the view that danger from sparking is largely independent of voltage. To avoid this sparking danger, he continued, it is necessary to isolate or limit the volume of explosive mixture which might be ignited under normal conditions of working, preferably by arranging for circuits to be made and broken under oil; or if this be impracticable, as it is if the current be continuous, arrange the break in properly designed explosion-proof chambers.

In speaking of the features of the cable system, Mr. Nelson at once expressed a great preference for three-phase working, and continues :—That the transmission system in shafts and roadways should be well insulated goes without saying; and wherever there is reasonable ground, following a chemical investigation, for assuming that the water in the pit will not attack lead, a lead-sheathed and armoured cable is recommended. The alternative is fibre insulation with a sheathing of vulcanised bitumen instead of a sheathing of lead; the latter is preferred as better mechanical protection, but this is one of many points which cannot be decided from general considerations. Cables of good design insulated by vulcanised bitumen only have been successfully used, even in mines where the roof and sides are unusually unstable, it being held that cables of this kind have some advantage from the point of view of keeping supply going in the event of damage from a fall. This is an important consideration; but the inherent disadvantages of an unarmoured cable system appear overwhelming. One of the chief uses of the lead sheathing is to provide a continuous metallic covering (in addition to the armouring) which may be earthed. For this reason, if an armoured cable with vulcanised bitumen insulation is decided upon, a continuous copper sheath may be used instead of a lead sheath. But whatever type of cable be installed, both metallic sheathings, the armouring and the lead (or copper), should be connected to two earth-plates—one at bank and the other underground—both placed in carefully chosen surroundings. Where disconnecting boxes and joint-boxes are inserted, the cable armouring should be securely fastened in metal outlet boxes so as to secure good mechanical and electrical connection. The necessary end-connections, probably of rubber-covered cable, should be protected by an earthed steel pipe properly bushed if there is any danger to the attendant of accidental contact, and they should also, if possible, be carried overhead and in sight. If a floor trench is unavoidable, the cables may be supported on porcelain insulators and the trench filled with clean dry sand or slag-wool to keep it free from vermin.

Electrical circuits are ordinarily protected in two ways :—(1) By fuses, and (2) by maximum cut-outs fitted to main control switches; but a moment's consideration will make it clear that if a heavy fall were to take place, cutting the cable and slightly separating the two ends, or bringing the armouring into contact with live metal, and should the mishap occur in a gaseous mixture, all the elements of an explosion would be present. For this reason the provision of merely a fuse or a maximum cut-out does not, in the writer's opinion, afford complete protection. There is, however, already on the market a method of protection which, it is suggested, may offer a solution of the difficulty. The action of this system, which is known as the Merz-Price system (see ELECTRICAL ENGINEERING, Vol. III., p. 763), depends upon the physical fact that the current leaving a length of cable is exactly equal in amount to the current entering that length of cable, if the conditions be normal—that is to say, if there be no leakage of current from the cable between the point of entry and the point of exit. One method of applying this principle is to make the difference in electrical conditions caused by leakage between the point of entry and the point of exit operate a trip-gear, and thus open the circuit immediately the leakage begins to occur.

Apparatus working on this principle would not operate when ordinary working overloads, not accompanied by leakage, occur. It is, however, easy to adapt such apparatus so that it combines all the features of an ordinary maximum cut-out with its own characteristic as regards leakage. When adapted in this way, the gear, though unaffected by temporary overload, would not only open the circuit in the event of a heavy and maintained overload, but would also and nevertheless operate instantaneously if an actual leakage of current began. For instance, if a cut-out of this type were placed above-ground, and through it power were fed to a distribution point in the pit below, a leakage on any one of the individual motor circuits fed from such distribution point, or a leakage on the main cable down the shaft, would operate the cut-out gear instantaneously, whilst ordinary overloads—unless greater than a pre-determined value and maintained for an appreciable period—would not operate it. A better plan, perhaps, would be to install cut-out gear on each individual motor circuit at the main distribution centre below-ground, and to provide pilot wires in the main shaft-cable feeding such centre. If balanced protective gear were then installed on the shaft-cable, the cut-out above-ground would not operate unless a leakage actually occurred in that cable. Thus, although a leakage on a motor-circuit underground would at once operate the cut-out controlling that circuit, the cut-out above-ground would remain closed, and all the motors except that on the faulty circuit would continue to run. Although this latter scheme ensures against needless interruption of supply, a point in favour of the arrangement first mentioned is that with it the operation of the main cut-out each time that a leakage occurs anywhere below-ground gives direct warning to officials above-ground that danger exists. By locking the cut-out in the open position, those in charge above-ground can then prevent risk of further damage at the point of leakage, pending a proper investigation into the cause of the interruption.

One point on which there may be unanimity is in the use of well-protected but unarmoured trailing cables for coal-cutters. Such cables should, however, be provided with an extra wire, or pair of wires, for the purpose of ensuring a good earth connection for the machine frame. A gate-end switch, hereafter described, seems to secure this result in practice most effectively. Additional protection over and above heavy braiding is required by trailing cables, and the most successful forms of protection seem to be plaited leather and a hard light rope covering, the latter wound round the cable spirally. Rope protection has some advantage in cheapness and in the ease with which it can be repaired.

Mr. Nelson summarised the general requirements of colliery switchgear as follows :—Accidental contact with any live metal should be rendered impossible by an earthed metal outer covering. The make and break in the case of three-phase circuits should be under oil. The design should be such as to preclude the possibility of coal-dust, dirt, or moisture diminishing the insulation. There should be a minimum amount of cleaning necessary to maintain the gear in good condition. Ready means should be provided for making the whole or part of the apparatus dead, so that inspection and cleaning may be done in safety. The construction should be fire-proof and mechanically strong, so as to resist rough usage. The switch must be of ample capacity; that is to say, it must be capable of breaking with safety and certainty the maximum power which may instantaneously pass through it under any conditions. There should be automatic protection for each circuit.

The usual method of making a gas-tight joint is to use a rubber-joint ring, and if the flange be of ample width covered completely by rubber-joint cloth of proper thickness, a satisfactory gas-tight joint should be readily obtainable. In the case of boxes often opened, a plain "metal-to-metal" joint is probably the best solution, either a flange joint, or a turned and fitted V and groove. The modern tendency is, however, to construct "explosion-proof" rather than gas-tight joints, as the

Digitized by Google

mere blowing of a fuse on a heavy short has been known to shatter the cover of a completely enclosed fuse-box. The writer has recommended a metal-to-metal joint, and the flanges should not be less than 1¼ in. wide. The principle underlying this construction is that of the Davy safety-lamp. The theory is that even if an explosion were to take place inside the fuse or switch-box the flame would become effectively cooled in passing through the minute openings caused by the machining of the surfaces in contact.

One feature common to many switch and fuse-boxes in present use appears to the writer to merit emphatic condemnation, namely, the combination of a narrow rubber-joint ring with a hinged box-cover. A safety joint should be made by dropping the cover flat in its final position, and it should be secured by bolts in the same way as is a steam joint. But the fewer the boxes that require bolted joints in an installation the better. At the present moment there is difficulty in obtaining oil-break switches with overload trip coils which will operate on circuits carrying less than 100 amperes. It seems to the writer that a reliable oil-break switch with an overload attachment for use on motor circuits of 10 horse-power and upwards would, practically speaking, do away with the necessity for fuse-boxes on motive-power circuits, besides affording other advantages in greater rapidity and certainty of action in opening circuit. Where fuses are unavoidable, it should not be forgotten that totally enclosed fuses of the "cartridge" type, which do not burst, it is claimed, even on a dead short, can now be readily obtained in all sizes. The writer has also heard a suggestion which may be of practical value, namely, that fuse-boxes might be packed tightly with slag-wool where it is thought that danger exists of igniting gas.

With regard to electrically-driven coal-cutting machinery, the author desired particularly to call attention to a gate-end switch for coal-cutters, designed by Mr. H. J. Fisher, of the Lambton collieries, Durham, which has, it is claimed, the following important features: The switch is totally enclosed in a cast-iron box, so that no live parts are accessible to an unauthorised person. Attached to the switch-box at one end is a dividing box with glands and clamp to secure the armour of the incoming cable and to efficiently earth the box. At the opposite end is a socket for the plug attachment of trailing cable. The latter plug when in place is interlocked with the switch, so that it cannot be withdrawn when the switch is closed; that is to say, it cannot be withdrawn when carrying current. An adjustable overload release with "time-lag" operates on each pole, removing the necessity for fuses. There is also a "no voltage" release. The switch must have a special trailing cable with an additional pair of small cores, making a five-core plug and cable for a three-phase machine. This additional pair of cores (which does not appreciably increase the cost of a trailing cable, as the cores are small) is connected to two points on the coal-cutter frame; and the arrangements are such that unless this pilot circuit from switch to frame and back again to switch is complete, the current traversing it being at earth potential, the gate-end switch cannot be closed. The effect is that unless the frame of the coal-cutter be properly earthed the gate-end switch will not operate; and if at any time during the working of the coal-cutter the pilot circuit in the trailing cable is broken by mechanical damage, the gate-end switch at once opens circuit. A small switch on the plug at the coal-cutter, connected so as to break the above-mentioned pilot circuit, enables the man operating the machine to cut off supply instantly at a critical moment. If then this switch be left open, it prevents anyone switching on supply at the gate-end switch while inspection or repair is under way.

The three-phase system enables oil-immersed switches, controllers, and even resistances, to be used when otherwise the circuit would require to be broken in air—an advantage almost sufficient, if none other existed, to justify the preference. In wet or very dusty places oil-immersed resistances are recommended. Where there is no possibility, with ordinary care, of a short circuit across exposed live parts from the accumulation of coal-dust, ordinary grid resistance-boxes may be installed in a motor-room or annex. The use of wire with "slow-burning" insulation and asbestos covered is recommended for resistance and controller connections.

The protection of motors was dealt with in a recent Paper by Mr. Simon, read before the Glasgow Local Section of the Institution of Electrical Engineers (see "ELECTRICAL ENGINEERING," March 25th, page 283).

The conclusion reached was that what is called "plate" protection affords sound mechanical protection together with what is lacking in the case of totally enclosed motors, namely, ventilation. But Mr. Simon recommends the grouping of the motors whenever possible in the neighbourhood of main air-ways, in separate rooms separately ventilated with intake air, so as to avoid altogether the necessity for any special protective device.

Whether continuous or three-phase current be used, the motor should have no exposed terminals, but if any, they should be mounted on incombustible insulating material, covered and hermetically sealed; or, in the alternative, short lengths of cable should be brought out through suitably bushed openings in the motor-case for the purpose of jointing to the incoming service leads, the joints to be made by connectors or otherwise.

With regard to transformers, the same general remarks apply to protection of terminals as in the case of motor terminals. Transformers for use underground are almost universally oil-cooled. A difference of opinion, however, exists as to the earthing of the neutral point of each transformer secondary. In the writer's view it is better to earth these neutral points, as immediate warning is then given at the transformer station of an earth on any one of the outers by the automatic opening of the faulty circuit, whereas in the other case a fault may not be discovered for some little time, even though a static earth detector may be in use, and in the meantime the insulation of parts of the system may be subjected to unnecessary and unaccustomed strain.

The Paper then passes on to deal with underground lighting. The widest latitude is given by the Home Office Rules on the subject of wiring for lighting circuits, but in the writer's opinion two systems only are possible:—(*a*) Open-type wiring, the wires being supported on porcelain insulators, and (*b*) a stout steel smooth-bored pipe (which may be protected from corrosion externally and have an insulating internal casing) to contain the wires.

ELECTRICAL MARINE PROPULSION

MR. W. P. Durtnall has written to us calling attention to our report of the discussion on a Paper by Mr. A. P. Chalkley, on the "Electrical Equipment of Liners and Battleships," read about three months ago before the Newcastle Section of the Institution of Electrical Engineers (see ELECTRICAL ENGINEERING, March 4th, p. 203.) That report stated that in this discussion Mr. Durtnall had advocated the use of 240-volts three-phase for auxiliary plant and 100 volts for lighting. Mr. Durtnall, however, points out this is not quite correct, as in his system he recommends the use of three-phase star-connected generators, with 250 volts between the phases for the motors, and the use of 145 volts between one phase and the neutral connection for the lighting, balancing the lighting on the different phases, and taking advantage if desired of the possibility of using a small auto-transformer on each section of the ship with low-voltage metal filament lamps. Mr. Durtnall in his letter recapitulates some of the arguments which he has advanced on several occasions in favour of employing electrical transmission to enable high turbine speeds and low propeller speeds to be used for the propulsion of ships, and states that there is no reason why, with the smaller diameter high speed turbines which he proposes, superheats of 100° to 150° F. and a 28-in. vacuum should not be used at sea, and economies in steam consumption reached equal to those obtained with large turbines on land: indeed, he states that, in the case of 16,000-h.p. sets, large firms who have investigated his system will guarantee a steam consumption per kw.-hour of 11 lbs. with 180 lbs. per sq. in. steam pressure, a superheat at 150° F., and turbines running at 800 r.p.m. This, he claims, would give in a ship with four such sets with his transmission arrangements, 8·6 lbs. of steam per shaft horse-power, as against 12·77 lbs. obtained on trials of the *Lusitania*. Mr. Durtnall informs us that he has in hand schemes for ship propulsion on his "Paragon" method which will use gas engines up to 2,000 b.h.p. for driving variable periodicity generators, enabling a variable speed to be given efficiently to squirrel-cage induction motors, which are, in his opinion, the only motors that are really suitable for heavy work at sea. He has also designed systems of transmission depending likewise on the control of squirrel cage motors by frequency variation for both railway and road traction.

North-East Coast Institution of Engineers and Shipbuilders.—A joint meeting of this association with the Institution of Engineers and Shipbuilders in Scotland is to be held in Glasgow on August 4th, 5th, and 6th.

Electric Lighting Acts (Amendment) Bill.—The Finance, Audit, and Requisition Sub-Committee of the Sheffield Corporation recommend that an endeavour should be made to have inserted in the Electric Lighting Acts (Amendment) Bill a clause prohibiting "unauthorised" companies or persons from giving a supply of electricity within the area of an authorised distributor.

STREET LIGHTING IN BRADFORD

SINCE the publication of our article last week (ELECTRICAL ENGINEERING, June 3rd, page 517), containing some results of comparative tests of experimental installations of gas and electric lighting at Bradford, Mr. T. Roles (City Electrical Engineer) has sent us further curves with a view to giving some explanation of the method by which the illumination curves which we published last week were obtained. It appears that actual measurements of the illumination in candle feet were not

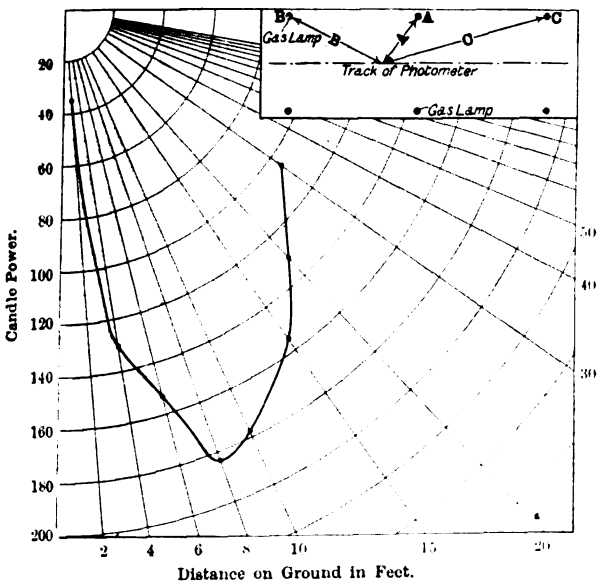

FIG. 1.—CANDLE POWER CURVES FOR GAS LAMPS.

made, but the photometer (a Simmance-Abady instrument) was employed to make various measurements of candle-power, from which the values of the illumination were afterwards deduced. The photometer was taken along the centre of the street as shown in the diagram in the corner of Fig. 1, and at each point readings were taken of the candle-power of three lamps, A, B, and C. The values of the illumination corresponding to these

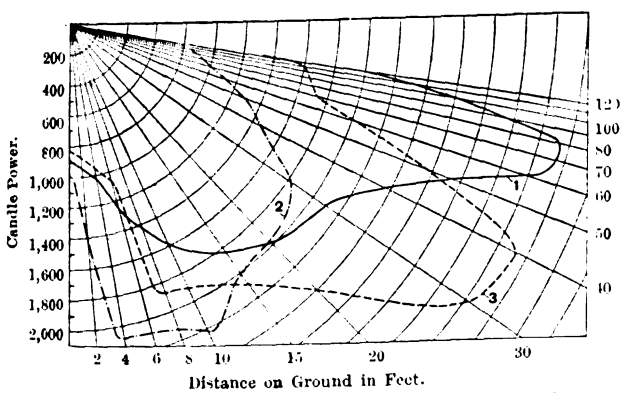

FIG. 2.—CANDLE POWER CURVES FOR EXCELLO ARC LAMPS (10 AMPERES, 45 VOLTS).

Readings taken 4′ 3″ from Ground.
Lamps 25′ 3″ from Ground.

2. With pear-shaped opalescent globe.
3. With reflector and pear-shaped opalescent globe.

(All with yellow flame carbons.)

results were added together and doubled in order to include the illumination from lamps on the opposite side of the street. This method is open to a certain amount of criticism. First, there is some difference of opinion as to whether the illumination in the centre of the road is the best criterion of the lighting of a street, and, secondly, it may be argued that it is hardly fair to double the illumination to obtain the joint effect of the two sides of the road, as in the actual use of the light for reading, examining objects, looking at one's watch, &c., it is seldom that the light from both sides at once is utilised. In Fig. 1 the candle-power curves for the gas lamps are given, while Fig. 2 gives the corresponding curves for the arc lamps with various different forms of globe. The variations in distribution obtained with these globes are very marked. The calculated curves of illumination for the arc lighting are given in Fig. 3. We have not before us the actual process by which these were deduced, but we presume that the results are intended to represent the illumination of a horizontal surface for a single lamp. The method of allowing for the effect of the adjacent lamps in the preparation of the final curves, published last week, was of course the same for the electric lamps as

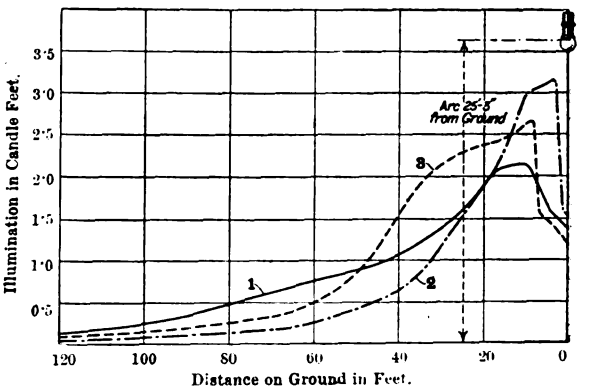

FIG. 3.—ILLUMINATION CURVES FOR ARC LAMPS.

1. With dioptric inner globe and opalescent outer globe.
2. With pear-shaped opalescent globe.
3. With reflector and pear-shaped opalescent globe.

for the gas lamps. As both sets of lamps were at the sides of the road the measurement along the centre of the road form a fair comparison, and the questions of whether vertical or horizontal illuminations are considered, and whether the illumination on the ground level, or, as is more usual, a few feet above, are immaterial in the present case as the object of the tests was a comparison between the two methods of lighting, and in these respects they were on equal terms.

ADELAIDE TRAMWAYS UNDERTAKING

IN the year 1906, the horse tramways of Adelaide were purchased by the Government for a sum of £280,000, and a trust, comprising two members of the Government and six local representatives, was appointed to deal with the electrification. The present chief engineer and manager, Mr. W. G. Goodman, was appointed in May, 1907. The following notes on the system are taken from *The Australian Mining Standard* :—

The system at present being electrified includes 54 miles of single track, 4 ft. 8½ in. gauge, consisting of grooved girder rails of British standard section No. 2, length 45 ft., weight 95 lbs. per yard, secured to hardwood sleepers. The rails are connected by thermit welds with fished expansion joints about every 350 ft., such joints being bonded with double flexible concealed copper bonds. The rails were made at the North-Eastern Steel Co.'s mills, at Middlesbrough, England, of silicon steel, with the heads hardened by cold water jets during final rolling. At points on the track where water would collect, cast-iron track drain gratings are provided, holes being drilled in the bottom of the groove of the rail to permit of drainage into a concrete box drain on which the castings are bedded. Throughout the city the tracks are spaced 12 ft. apart, centre to centre, and the overhead wires are carried on cross-arm poles. In the suburbs, span poles are used. The trolley wires (No. 3/0 B. & S. gauge) are strung centrally to the tracks; the greatest deviation at curves is limited to 12 in., as the trolley wheels are of the non-swivelling pattern. All ears are mechanical.

One section of the line is fed entirely with overhead feeders from a converter sub-station at Thebarton. The rest of the system is fed from the city sub-station, from which the feeders leave underground; some run direct to the switch pillars, while others are carried partly overhead as bare conductors along the tramway poles. Steel-armoured rubber-insulated cables are used to make connection between the switch pillar and the overhead lines or trolley wire tappings. Section insulators not bridged by switch pillar connections are provided with switch-boxes clipped to the adjacent pole to allow of feeding through when required. The feeders and returns are single-core paper-insulated cables sheathed with lead, as the risk of decentralisation with vulcanised bitumen cables was considered too great in Adelaide's hot climate. The standard sections adopted vary from 0·9 sq. in. to 0·2 sq. in., and an average current density of 350 amps. per sq. in. has been aimed at. The feeders necessary for the future extension to the outer area have been laid

Digitized by Google

already; including these, there are seventeen feeders and eight returns. Of the latter, four are direct returns to the negative bus-bar with a total area of 3·35 sq. in. of copper; the other four are connected to more distant parts of the system, and are used in conjunction with negative boosters when necessary. The solid system of laying has been adopted, and, as white ants eat pitch, the filling has been rendered poisonous by the addition of white arsenic. Pilot and telephone wires are, for the greater part, carried overhead, but in the city they are laid underground. Complete metallic circuits are used for all telephones, instruments being provided at intervals along each line and at all termini.

The high-tension transmission line runs overhead from the power station at Port Adelaide to Barton Terrace, North Adelaide, but then goes below ground for the last two miles to the city converter station. The cables are three-core, paper insulated, and lead sheathed, with a sectional area of 0·15 sq. in. per core. They are designed to withstand a normal working pressure of 11,000 volts both between phases or between any phase and earth, and are laid solid. The power station is at Port Adelaide, where there is an unlimited supply of condensing water and the minimum of coal handling. In the boiler house there will be three banks of water-tube boilers, fitted with integral superheaters, mechanical stokers, and economisers, the latter being so arranged that each bank of boilers has its own economiser. The feed water will be pumped through a steam heater, into which is led the exhaust steam from the auxiliary engines. After passing through the heater, it goes through the economiser and thence to the boiler. The coal bunkers will be mounted over the boilers. In the engine-room there will be three turbo-alternators generating three-phase current at 11,000 volts with a frequency of 25 cycles per second. Each alternator will be rated at 1,500 kw. on 95 per cent. power factor, and will have an exciter mounted on the turbine shaft. For the supply of light and power in the station there will be two 210-volt compound wound dynamos of 150 kw. capacity direct connected to high-speed reciprocating engines. There will be a two-storey gallery for the high-tension gear, entirely walled off from the engine-room. The control switchboard will be erected on a gallery at the end of the engine-room. Due care has been paid to provision for extensions. The boiler house may be doubled in capacity, and in the engine-room space is left for a turbine of 3,000 kw. capacity and a 300 kw. auxiliary set.

There are two converter stations at present. In the city station there will be five rotary converters, each rated at 500 kw., 600 volts. Each will work from three single-phase transformers connected in delta. The transformers are of the oil-insulated type, and cooling coils are fitted in the top of each case for keeping the temperature down when heavy loads are experienced. The synchronising of the machines is carried out on the low-tension side, starting up being effected on the D.C. side. All high-tension switches are of the oil-immersed remote control type, and are motor operated. The switchboard is 78 ft. long. All cables are in earthenware conduits, but the low-tension connections between the transformers and the low-tension A.C. panels are composed of solid copper rod carried on insulators on a special steel framework. Positive and negative feeder boosters will be installed in both stations, together with battery boosters of the Highfield automatic type. Both stations are equipped with Tudor batteries, the city converter station containing one with a capacity of 1,000 ampere-hours at one-hour rating, and the Thebarton station with a capacity of 300 ampere-hours at the same rating. The station at Thebarton is similar in all respects to the city station, with the exception that one 300-kw. and two 150-kw. machines are installed with provision for a second 300-kw. machine. The high-tension transmission line enters this station overhead.

The cars which are already running on the finished section are of two types, viz., four-wheel open and four-wheel combination, thirty of each. The vestibules are fitted with collapsible gates, and in order to prevent passengers from entering upon or alighting from the cars on the off side, a barrier is provided. The steps are so constructed that only one can be used at a time, the folding of the open step opening that which has been closed. The trucks are of the Brill 21 E type, with a nine-foot wheel base. Four magnetic brakes are fitted to each car. Peacock hand brakes are also fitted. The motors are the British Westinghouse No. 200. Oil lubrication is used, provision also being made for the use of grease. Parallel trolley wiring is used, a circuit breaker being at either end. The Wilson and Bennett type of life guard has been installed. The car depôt, situated about a mile from the centre of the city, has accommodation for 200 cars. It is divided into four bays, each containing six tracks supported on concrete piers. An installation for supplying compressed air for car-cleaning purposes is provided, and a motor-driven traverser conveys the cars from the depôt to the repair shops. The machine, armature, and truck shops contain overhead cranes, and are completely equipped with machine tools. The work was commenced in June, 1908, and a section of the line was opened in March last. Other portions will be opened shortly.

STEAM v. ELECTRIC TRACTION

ON Thursday last, at the Royal Institution, Prof. W. E. Dalby, of the Central Technical College, South Kensington, delivered the first of two lectures on the relative merits of steam and electric traction for railways. The lecturer said that he wished to put before his audience the various considerations which determined the system most suitable for any given case. Where there was no water-power available, the energy utilised for traction was in each case converted from heat into mechanical energy. In the case of the locomotive, for every 100 heat units at the fire grate, 30 escaped in the flue gases, and 70 were transferred to the boiler; of these last, 65 went in the exhaust steam, leaving only 5 heat units to be delivered to the engine. Only 4 out of the 100 units were actually utilised for traction. In the case of the electric railway, for every 100 heat units at the grate, 78 were transferred to the boiler, and of these, 10 were taken up by the engine, as against 5 in the former case, owing to more efficient plant. Of the 9 units delivered to the generator, about 1 would be lost in the generator, 1 in the line, and 1 in the transformer or other converting plant. In the end the energy actually utilised for traction would probably be the same as in the case of the locomotive, as, of the 6 units delivered to the motors, only 4 would be usefully applied. In the case of an electric train, however, there was much less dead weight to be hauled.

The final aim of all these energy transformations, continued the lecturer, was to exert a couple at the axle. This couple must not exceed the amount necessary to cause the wheels to slip; at starting, the maximum value was $W\mu$, or the product of the weight per wheel multiplied by the friction coefficient. The friction coefficient could generally be taken as one-fifth, although it could be increased by applying sand to the rail. For steam locomotives the value of the drawbar-pull corresponding to this maximum couple was about 18 tons for single driving-axle engines, but could be increased to as much as 67 tons by coupling four axles together. For a given cylinder-power, the smaller the wheels, the larger the pull that could be obtained. This large drawbar-pull was only exerted at starting. As the rate of working was equal to the drawbar-pull multiplied by the speed, it would be seen that a pull of four tons exerted at a speed of 60 m.p.h. would correspond to 1,800 h.p., a much larger h.p. than any locomotive boiler could maintain. The electric locomotive was not limited in this way. By increasing the load on the driving-wheels and the power of the motors geared to the axles, almost any drawbar pull could be attained; it was merely a question of expense. This pull could also be maintained at high speeds, and very high velocities could be reached, as was demonstrated on the Berlin-Zossen experimental line. Over 1,500 h.p. was required, however, to keep up the speed of a single car on this line at 112 m.p.h., whereas the Scotch express, with several carriages, was run at 55 m.p.h. by a locomotive developing only 1,000 h.p. High speeds were quite feasible, but the travelling public would not pay for them.

Finally, Prof. Dalby pointed out that, for the hypothetical case of a railway between two towns 100 miles apart, and for speeds up to 50 miles per hour, one could not use anything more commercially satisfactory than a steam locomotive. If a speed of 100 miles an hour were required, electric traction would have to be used; the cost of running would not then be covered by the ordinary 1d. per mile fares, however. In the next lecture, Prof. Dalby will deal with the other case of frequently stopping trains in which, he said, if high schedule speeds are to be attained, electric traction is inevitable.

The "G.B." Surface-Contact System.—Prof. J. T. Morris delivered a lecture upon the "G.B." surface-contact system at the East London Technical College on Monday evening. After describing in more or less popular language the principles of the working of the system, Prof. Morris repeated the experiment which Mr. Mordey showed at the Institution of Electrical Engineers a few weeks ago, in order to demonstrate how arcing at the studs can be extinguished by the aid of condensers. Prof. Morris, however, exhibited a working model of a section of the line. The lecturer concluded by expressing the opinion that the L.C.C., having taken the system in hand, should have persevered with it. Under a little more favourable conditions, and where the owners of the system were permitted to lay the track, the system was bound to be a success.

THE RADIO-TELEGRAPHIC STATION AT CULLERCOATS

AFTER the annual general meeting of the Newcastle Section of the Institution of Electrical Engineers on Monday, May 24th, at which the officers and committee named on page 462 of our issue of May 20th were duly declared to have been elected, an informal Paper was read by Mr. Aage S. M. Sörensen, on "The Radio-telegraphic Station at Cullercoats, near Newcastle," of which he is in charge.

The building of this station was completed about June, 1906. The mast is a lattice-built pole, which was completely constructed to its full length lying on the ground. After fixing the upper ends of the guys to the mast, it was lifted bodily into position by means of a derrick crane.

The antennæ originally took the form of an inverted fan, consisting of eight wires connected at the top, and about 60 ft. from the ground, spread at equal distances between two smaller masts, 150 ft. apart. The wires were connected to the inlet insulators on the roof, four wires meeting at each of the two inlets. The present antennæ are made in the umbrella shape. Eight wires are suspended between the top of the pole and eight iron posts arranged on the rocks and on land at nearly equal distances apart, in a circle round the pole. The upper 160 ft. of each wire forms part of the antennæ, and is separated by a long insulator of hard rubber from the rest of the wire, which only serves as a stay. The lower ends of the eight antennæ wires are connected by an octagonal boundary wire. At the top of the mast four wires come together on each side, and are there joined to two copper cables which run down to the leading-in insulators on the roof. The two half parts are suspended from the top of the mast by means of a series of porcelain insulators, and similar insulators are used to cut the guys into short lengths. The insulators are constructed so that the wires are looped into each other through the insulators, and in case an insulator breaks the wires will remain in position. The antennæ are made of seven-stranded, silicium-bronze wire, strand No. 20. The earth connection consists of 70 copper wires of about 2 mm. diameter, laid about 6 in. under the surface, and spreading from the centre of the cabin in all directions like spokes in a wheel. The average length of the earth wires is 130 ft. The interior of the cabin is divided into four rooms, of which three are occupied by the spark apparatus.

The engine-room contains a motor-generator and necessary regulating apparatus. The town supply at 480 volts is used. The dynamo is a single-phase alternator, which gives 90 to 120 cycles, and voltage from 300 to 600 volts. The cables pass through choking coils with spark arresters before they enter the operating-room where the telegraph key and a variable reactance are inserted in the circuit, which is completed in the third room—the spark-room—through the primary winding of a dry transformer. The secondary of the transformer is connected to the spark-gap, across which is shunted a battery of Leyden jars and a self-induction helix, forming the closed oscillatory circuit; the antennæ and the earth connections are taken off from two points of the same helix, thus forming a so-called direct coupling. As the fundamental wave-length of the antennæ is 800 metres, and the normal working wave is 600 metres, the antennæ are "shortened" by an inserted small battery of Leyden jars. Over these jars the antennæ are "interrupted" by an anchor spark-gap, which ordinarily leaves the antennæ disconnected from the sender, but during sending is bridged across by a spark.

As already mentioned, the operating-room contains the telegraph key, which is installed on the table beside the receiver, and also the ammeter and voltmeter for the power circuit. A branch of the antennæ comes into the operating-room to a switch by which it can be joined through a self-inductance and a condenser to earth. This apparatus forms the receiving circuit, which can be tuned by varying the capacity and the self-inductance. The condenser consists of a set of semicircular plates, which can be turned in and out in the spaces between a set of similar fixed plates, whereby the capacity can be altered. The helix has 100 turns of thick insulated copper wire about 1 mm. in diameter, and terminals at different places, arranged so that a number of turns in steps of five can be branched off. If self-inductance and capacity are arranged in series with the antennæ and earth, the receiver can be tuned to wave-lengths from 300 to 1,000 metres, and when the condenser is shunted across the inductance to wave-lengths of between 800 and 2,500 metres. Inductively coupled to the tuning helix is another coil, the ends of which are connected to the detector, in this case a De Forest electrolytic cell, by means of which the received energy is transformed into audible signals composed of long and short sounds in a telephone.

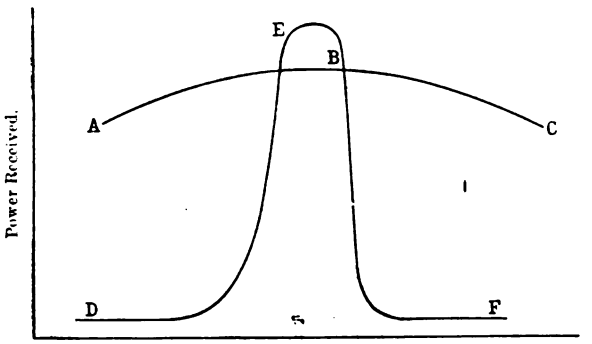
Ordinarily the operator on duty is constantly listening in this telephone, and on 600 metres wave-length. A ship intending to communicate with the station will send a call-signal with the names (in code) of the called and the calling station. To reply, the operator breaks the antennæ switch, which in its other position closes the circuit to the control relay of the motor starter, the motor starts, and in 10 seconds the transmitter is ready for making the reply. When this has been done, the antennæ are switched over again, the motor stops, and receiving conditions are immediately re-established. In this way the communication is kept up between ship and shore station as long as working requires.

Mr. Sörensen then proceeded to outline the principles of the Poulsen system, and mentioned that as early as November, 1906, a receiver of the Poulsen type was installed at Cullercoats, and at the first test signals were received from the Danish stations, Lyngby and Esbjerg, over distances of about 400 and 600 miles respectively. Early in 1907 an experimental arc was set up in Cullercoats, and very satisfactory results were obtained, considering the energy and the small antennæ then used. In 1908 the antennæ at Lyngby and Cullercoats were extended, and the stations equipped with generators of up-to-date design. It was mentioned above that the cabin at Cullercoats had four rooms, and the installations in three of them have been described. The fourth is occupied by the complete Poulsen installation, consisting of the two essential parts, sender and receiver.

The sender comprises the generator, the oscillatory circuit with capacity and self-induction, antennæ, and earth. As the oscillatory tension between the condenser plates is much smaller in a Poulsen arc sender than in a spark sender, it is possible to use condensers with air or oil dielectric of the design mentioned above, one advantage of which is that the capacity of the sender is readily altered, and as the distance between the plates only needs to be a few millimetres, the condensers occupy considerably less room than a battery of Leyden jars.

The generator is built in the following way: On an iron footplate are mounted two vertical iron cores, round which the magnetic field coils are placed. Above the coils an air-tight double-walled box is placed between the cores, and horizontal pole-pieces pass through the box on each side, an air space being left between them. The arc electrodes are passed through the end walls of the box, but are insulated from it, and are placed so that the arc is burning between the magnet poles. The copper electrode is in a fixed position, while the carbon holder can be moved to and fro by a screw for adjusting the arc length, rotated by a small motor through a worm-gear. Outside the box the electrodes end in metallic plates with radiators for air cooling. From a sight-feeder (such as is used for oil in gas engines) methylated spirit is dropped into the arc, and by its decomposition generates the necessary hydrogen atmosphere. The direct-current supply passes from the switch through a variable resistance, the magnetic field windings, and two air-cored choking coils, to prevent oscillations in the mains, to the arc electrodes.

Signalling is effected by letting the telegraph key short-circuit a part of the self-induction in the circuit, so that the arc is oscillating during the whole period of working, but two different waves are radiated, corresponding to marking and spacing. As long as the key is pressed the transmitter generates a persistent train of constant oscillations, and consequently nothing would be heard in an ordinary receiver for audible signals. To produce sound it is necessary to cut the oscillations up in groups, occurring with a frequency which can be heard. So far this cutting up could be effected in the sender or the receiver at will. By the "ticker," a very ingenious arrangement of Mr. Poulsen's, it is possible to employ this method advantageously in the receiver. The Poulsen "ticker-telephone" receiver consists of a primary circuit (the ordinary antennæ-earth circuit, with necessary self-inductance and capacity for tuning), which is in inductive and extremely loose coupling with a secondary closed circuit, composed of self-inductance and capacity. Across the secondary condenser is placed through an intermittent contact (the "ticker") a condenser of large capacity (in comparison with the condenser in the circuit), and across this condenser is placed a telephone.



The action is as follows: If the "ticker" contact is broken the secondary circuit is quite free—that is to say, no energy is taken from the circuit, and if set in oscillation from a sender through the primary, the secondary circuit will accumulate energy by integrating the impulses; after a certain time the ticker-contact is closed, the circuits thrown out of resonance,

Digitized by Google

and the secondary gives up the energy to the "block-condenser," which again discharges through the telephone; then the "ticker" closes again and the process is repeated as long as energy is forthcoming from the sender and of the proper frequency. In this way the signal is marked in the telephone by a ticking noise, from which the apparatus is named.

Detectors can be used without the "ticker" for printing arrangements. A specially sensitive type is the photographic printer, in which the feeble direct current obtained from the detector is passed through the fine wire in an Edelmann thread galvanometer. The wire moves in front of a slot, and through a microscope the slot is photographed, with the moving shadow of the wire, on a strip of sensitive paper. As the mass of the wire is extremely small, the speed is nearly unlimited, as long as energy enough is obtained to give a visible movement. In this way messages have been received in Lyngby from Erbjing at a rate of 300 words a minute, and at Cullercoats from Lyngby up to 100 words a minute.

Mr. Sörensen also made some additional remarks relating to the subject of the Paper. Referring to the fact that with direct excitation of the antennæ circuit the ratio between active and inactive intervals is small, he stated that owing to the strong damping effect the first five oscillations, of which there are 500,000 or 600,000 per second, are all that are useful, the greatest part of energy being derived from the first amplitude. This condition lent itself to long-distance transmission, but not to facility in tuning. As regards this latter point, he gave two approximate curves showing the difference between spark-excitation and arc-excitation, which are reproduced here.

POWER CURVES FOR ARC AND SPARK EXCITATION.

If the abscissæ show the frequency of oscillations and ordinates represent the power received, then the curve *ABC* represents roughly their relative values with spark-excitation, the curve being rather flat. Curve *DEF*, however, shows their values with arc-excitation. A small variation in frequency produces a large difference in power, rendering tuning or variation of frequency a good method of securing non-interference. Tuning to the extent of half of one per cent. is possible by an arc working in an atmosphere of hydrogen. Frequencies of 100,000 per second are necessary for radio-telegraphic transmission by arc-excitation, and the function of the hydrogen atmosphere is to bring the frequency above the maximum of 40,000 obtained with arcs working in air. The precise operation of the hydrogen is not yet understood, although it is found that the curve giving the relation between volts and amperes in an arc of fixed length is steeper in an arc working in hydrogen than that of an arc working in air It is also found that cooling the arc produces an improvement, and the later arcs, taking 4 kw. and upwards, are usually water-cooled, while others have large ribbed-metal heat radiating surfaces.

DISCUSSION.

Mr. G. G. STONEY (Messrs. C. A. Parsons & Co.), in proposing a vote of thanks, alluded to the sequence of research which, spreading over 80 or 90 years and beginning with Faraday's experiments in electromagnetic induction and reaching at present Poulsen's adaptation of the singing arc, had brought wireless telegraphy to its present stage.

Mr. A. E. DRUMMOND (National Telephone Co.), in seconding the vote, wished to know whether, and if so why, wireless telegraphy had been found practically useless during the late war? He understood that at the Modder River it had been tried and abandoned, and had heard the opinion advanced that this was due to large masses of ironstone in the neighbourhood.

Another speaker asked for information as to the speed of transmission. He wished to know whether the figures quoted in the Paper were day-by-day results, or whether they were the best returns of experimental working. It would also be interesting to know whether the results were obtained during daylight or at night. It was evident that 20 to 30 words per minute, which was the previously accepted working speed of wireless installations, was very limited. But if 100 words per minute, as quoted in the Paper, was really practicable, an important step in advance has been made which might alter the conditions of the whole problem.

Mr. SÖRENSEN, in his reply, referred particularly to the remarks of the last speaker. The experiments with the photographic printer at Cullercoats, though only an experimental demonstration for a certain party, lasted a week. There was a certainty of obtaining a normal of 60 words per minute, and occasionally 100. The governing factor was the power available. The relay and printer at the receiving end have a certain inertia of moving parts, and a certain amount of power has to be transmitted and received in order to actuate them. Experiments have proceeded for over a year, from which it is found that with an expenditure of 5 kw. at the transmitting station, 200 words per minute under any ordinary conditions of working can be sent 200 miles.

NEW COOLING TOWERS AT STUART STREET ELECTRICITY WORKS, MANCHESTER

IN view of the recent additions to the plant of the Manchester Corporation Electricity Works at Stuart Street, and the consequent greater volume of circulating water required for the condensers, two new cooling towers have been erected. The specification was to the effect that the towers were to be capable of dealing with 400,000 gallons of water per hour, reducing the temperature from 125° F. to 80° F. at an atmospheric temperature of 60° F. and a humidity of 60° per cent. The contractor was also called upon to guarantee that the loss of water through evaporation should not exceed 2½ per cent.

The towers, which are illustrated on the opposite page, have been supplied by the Blasberg Engineering Co. (C. Bradshaw), of Manchester. Fig. 1 is an elevation and side elevation of one of the towers. The upper part of the wooden tower is hollow and forms a chimney, and the lower part, known as the cooling stack, contains the rails over which the water drips. A view of one of the four sets of rails on a larger scale and a section at right angles to it is shown in Fig. 2, and also various details on a still larger scale.

The hot water is delivered to an open wooden main trough *A* at the top of each cooling stack, and four distributing troughs *BB* are led out of each of the main troughs *A* at right angles to them. Projecting through the bottom of these distributing troughs are a series of zinc tubes *bb*, the lower ends of which are submerged in the distribution channels *CC*. These channels are filled with water, which overflows in fine, even streams over the V notches at the top of the channels and falls on the cooling rails *DD* beneath. The shape of these "double-drip" cooling rails is shown in the detail drawing included in Fig. 2. The water spreads itself evenly over both the horizontal and sloping surfaces of these rails in a thin film, and falls in two fine streams on to the cooling rail beneath, and so on to the bottom of the tower. Attention has been given, in the spacing and arrangement of the cooling rails, to securing the division of the water into the greatest practicable number of fine streams, and the air passes up between the rails by the natural draught of the tower and cools the water. The construction and fixing of the bearer rails *E*, which support the cooling rails, may be particularly mentioned. They are notched, to suit the section of the cooling rails, so that the latter may be fixed in position without the use of nails or any other metal fastenings liable to corrosion. The bearer rails themselves are let into the posts of the cooling stack framework, and are flush with their face; they are held in position by means of a binding board or "keep plate," which is fastened to the posts by means of hard wood pins. This construction is Mr. C. Bradshaw's patent.

The wood of the cooling rails is not treated. With creosoted timber there is, we are informed, a danger of the creosote washing out and acting on the condenser tubes. To keep the timber in good condition the makers recommend that the water should always be kept running slightly in a cooling tower, whether it is in use or not, as alternate wetting and drying is more liable to rot the wood than if it is permanently wet.

THE "KEY" LEAD-COVERED WIRING SYSTEM

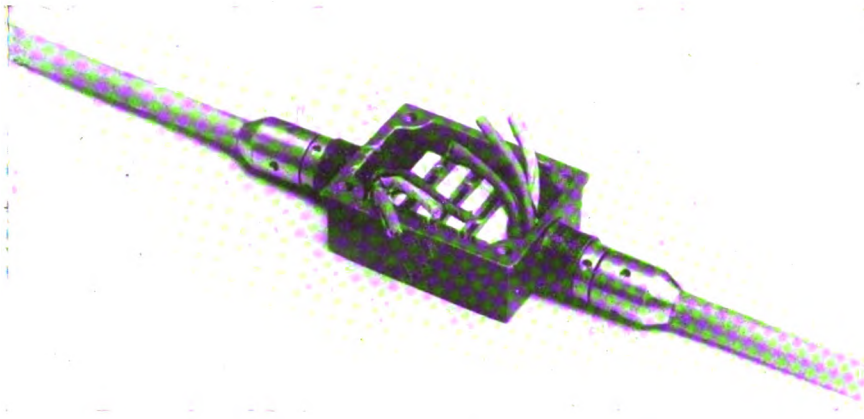

FIG. 1.—TWO-WAY BOX AND FITTINGS, ASSEMBLED.

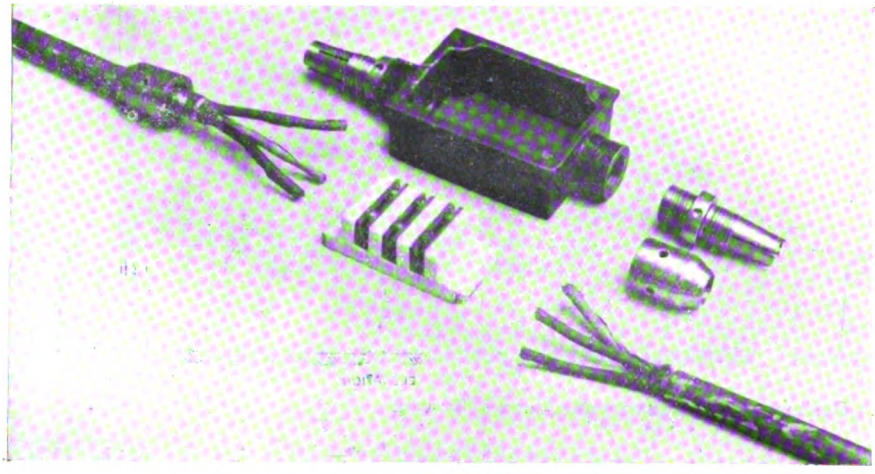

FIG. 2.—TWO-WAY BOX AND FITTINGS, UNASSEMBLED.

THE Key Engineering Co. (of 4 Queen Victoria Street, London, E.C., and 38 Deansgate, Manchester), have now ready for the market the ingenious lead-covered wiring system which they exhibited at the Manchester Electrical Exhibition. As is well known, lead-covered wiring systems present considerable advantages for surface work in many situations, especially for ship wiring, mining, and telephone work, battery rooms, &c. There are two difficulties in installing lead-covered systems: one is the proper sealing of the ends where the wires are led into the fittings, and the other is the making of moisture-tight and at the same time metallically-continuous joints between the lead covering and the junction-boxes, &c. The necessity of soldering the lead-covered wire to the boxes is a serious trouble and expense in installing such systems, and it is this particular difficulty that the "Key" system is designed to overcome.

Figs. 1 and 2 show the patent boxes and fittings that are used. An india-rubber ring is inserted into the screwed opening in the box, and rests against a shoulder left on the wall of the box for that purpose. A specially shaped nipple is then screwed partly into the box. The lead-covered wire is next trimmed in the ordinary way, and the circular nut which is seen lying between the wire and the nipple in Fig. 2 is threaded on to it. The cable is then inserted through the nipple into the box until the lead becomes flush with the inside of the box. On screwing home the nipple, it squeezes the rubber against the shoulder already mentioned, causing the ring to grip round the lead as in an ordinary gland; the nut is then screwed on to the nipple, causing the latter to grip the lead tightly. The connections of the wire inside the box are made by means of porcelain terminal blocks into which the wires are screwed. The arrangement is made very clear by the two illustrations.

THE MINES EIGHT HOURS ACT AND ELECTRICAL HAULAGE

AN article in the *Iron and Coal Trades Review* points out that one effect of the new Mines Eight Hours Act, shortly to come into operation, will be to increase the utilisation of mechanical haulage underground, particularly for auxiliary haulage in-bye. The immediate result of shortening the working hours will probably be the difficulty of finding a sufficient number of youths and boys to remove the coal from the working faces and deliver it to the main haulage roads, and this will especially be the case where the colliery is situated some distance from a town, and has only a limited population to draw upon.

There are numerous underground roadways in which the haulage is done either by manual labour or by a number of ponies, each one requiring a driver, where a small mechanical haulage attended by a boy would dispense with the ponies altogether, and only one or two boys need be retained for coupling the tubs on to the haulage rope. This, in addition to partially solving the problem indicated, would incidentally reduce the working costs. In a particular case the recent installation of a small endless rope gear costing about £130 dispensed at once with six ponies and their attendant drivers, and the cost of upkeep, including grease and oil, worked out at about 12s. 6d. per annum.

Where roadways are sufficiently wide to permit of the laying of a double road the endless rope system is to be preferred, both from the point of view of power required and from the fact that the coal is delivered more regularly. Owing to the new Act there should also be an increasing demand for small single-drum main rope gears or winches for use in dip workings. For narrow roadways, where there are not sufficient gradients to enable the empty set to be taken in by gravity, there remains the main and tail rope system. For any of these three types of gear, when installed a distance from the boilers, there is little doubt that electricity is the most economical and adaptable motive power.

The article then passes on to consider in detail some points in the mechanical design of haulage gears, and, in dealing with the motive power required, remarks that it cannot be too strongly emphasised that the motor should have a reserve of power to deal with emergencies. The derailing of one or two full tubs considerably increases the demand on the machine, and the reserve is also exceedingly useful when it is required to move the set along to assist in replacing the tubs on the metals. As these auxiliary haulages are also frequently required to be removed from place to place, the demand in one position may be considerably greater than in another, and again, as the voltage available is usually found to be less as the machine is taken further in-bye, all the available torque of the motor is reduced.

With regard to controllers for haulage gears, it is remarked that, where precautions against explosions are not essential, a liquid starting-switch will usually be found to give good results. Its great advantage is the perfectly gradual variation obtainable in the motor speed and the possibility it gives of actuating the set without a series of jerks. A further advantage is that where a motor does not remain in one place for any length of time, and the duty it may have to perform varies, the resistance of the starter can also be varied within wide limits by simply varying the acidity of the liquid. The liquid starter is not recommended for heavy and frequent use, unless provision can be made for cooling it, as under these conditions the liquid rapidly evaporates and requires replenishing, and the vapour given off is undesirable in the neighbourhood of electrical machinery. Under such conditions a metallic-type tramway controller will give the best results.

REVIEWS OF BOOKS

Hydro-Electric Practice. By H. A. E. C. Von Schon. 372 pp. 9¾ in. by 7¼ in. 140 illustrations. (London: J. B. Lippington Co.) 25s.

IT is rightly pointed out in the preface that "hydro-electric power development is a much more complex undertaking than a large majority of the promoters of such enterprises realise when the subject is first approached," and it is for the use of those scheming out water-power projects that this work is intended. The first portion deals with the commercial rather than the engineering aspect of the subject, and gives information of a nature required in estimating the possibilities of success in developing a particular water-power site. It is especially urged that the probable market for the power produced should be investigated fully before the more engineering details are proceeded with. This section contains many useful curves, and an actual example of a detailed report upon a projected scheme in America. The second part of the book is of a more technical nature; methods of surveying are first dealt with in a thoroughly practical way, and then follows the largest and best section of the book, in which full data of both a quantitative as well as a qualitative nature are given relating to the purely civil engineering side of the development and constructional works. A good deal is to be found here not ordinarily included by authors of general engineering works. It may be remarked at this stage that the whole book deals more with American conditions than those prevailing on this side of the Atlantic, but this, although it should be borne in mind by the reader, does not seriously detract from its value. Its American origin should likewise be remembered in criticising peculiarities of expression. The chapter headed "equipment," which fills the last hundred pages or so, is practically the only part of the book where electrical engineering *per se* is dealt with, but it is only the last half of this which is devoted to electrical matters. In this small space an attempt is made to outline the principles of electricity and magnetism, to explain the action of the dynamo, and to give engineering information regarding the construction of transmission lines, &c. With the exception of the transmission line section this part of the book would be better omitted, as, especially in the elementary portions, the author has not done himself the justice that he has in the hydraulic section, and has allowed incorrect definitions of terms to creep in.

While we might recommend the book to the electrical engineer wishing to widen his knowledge of hydraulic matters, we would not put it in the hands of a hydraulic engineer wishing to become acquainted with the principles of electrical engineering.

A Pocket Book of Electrical Rules and Tables. By the late John Munro and Andrew Jamieson. Nineteenth edition. 810 pp. 5 in. by 3½ in. (London: Charles Griffin & Co.) 8s. 6d.

OUR old friend, "Munro and Jamieson," is too well known for it to be necessary to say much as to the general features of the latest and nineteenth edition of this popular work of reference. In outward form it remains the same—still truly a pocket book—but even in the short period since the last edition it had been found advisable to add some 132 pages of new matter and to delete over 100 pages of that which had become out of date—a revision on a somewhat more extensive scale than that preceding the last edition. The latest form of the wiring rules of the Institution of Electrical Engineers is now included, together with the Institution's model form of general conditions and certain Board of Trade and other Regulations. Naturally, there has not been time to include the new Home Office Rules for Factories and Workshops, but that the omission of the Home Office Rule for Electricity in Mines has not been rectified is surprising.

The greater part of the revision appears to have been in the section devoted to what we may call the heavier branches of electrical engineering, but excellent as are the sections addressed to the "milliampere man," we do not think that the sketch of submarine telegraph methods can be called up to date without a reference to Mr. S. G. Brown's cable relay. We do not look for the same completeness in the power and lighting sections, as the author obviously intends to provide for the requirements more particularly of the laboratory and test room. A good deal has, however, been done in bringing what there is up to date. We still seek in vain, however, in the index for the words tantalum, osram, or even metal-filament, and although the chapter on lighting is supposed to have been revised, we find but scant reference to the new lamps which are having such an effect on the electrical industry. Neither are their capabilities nor their limitations adequately set forth, and such things as the possibilities of the 25-volt metal-filament lamp are completely ignored.

A new section on dynamo and motor design by Mr. W. B. Hird has been added, which for some reason comes under the general heading, "Principle of the Magnetic Circuit." The space allotted, however, does not permit of much consideration of the features of modern central station machinery. For the same reason, probably, it has been found possible to enter into the requirements of modern switchgear, and electric traction, as heretofore, is outside the range covered. Much of the value of the book lies, as it always has done, in the completeness of the testing section, in itself a considerable portion of the volume; and the unavoidable limitations imposed by the very magnitude of the subject on other portions of the book in no way detract from this sphere of its usefulness.

ELECTRICITY SUPPLY IN SYDNEY

IT will be remembered that Major Cardew, of Messrs. Preece & Cardew, London, went to Sydney a few months ago for the purpose of making a report on the working and proposed extensions of the electrical undertaking of that city. This report has now been issued, and some portions of it were published in a recent issue of *The Australian Mining Standard*. The growth of the undertaking has been far more rapid than as predicted when the original installation was put down, and the annual output now amounts to 9,000,000 units, most of which is distributed within the city. Immediate and extensive additions to the plant are urgently needed, however, and Major Cardew approves of the proposal of Mr. H. R. Forbes Mackay, the City Electrical Engineer, to adopt 4,000 kw. turbo-alternator units. A suggestion to install a 400 kw. D.C.-turbo-generator for running the auxiliaries is not approved, however, as it is thought that one of the existing reciprocating sets could be made available for this purpose. Incidentally, Major Cardew expresses the opinion that reciprocating engines are preferable to turbines for units below 1,000 kw. capacity. In connection with the extension of the power house, he advises that wharfage accommodation opposite the station should be secured, and either a coal elevator with a gravity conveyor, or a horizontal belt conveyor, constructed. The cost of such plant is estimated at £6,000, but it is stated that a saving of one shilling per ton on the cost of coal will be effected in this way. The total capacity of the proposed new plant is over 38,000 h.p.

Referring to troubles experienced with condenser tubes at Sydney, Major Cardew says that these have been very generally experienced of late, and describes different methods of protecting the tubes from corrosion based upon electrolytic action. Messrs. W. H. Allen, Son & Co. use plain brass tubes in conjunction with cast-iron water boxes and end covers, the tube plate being of the same composition as the tube. Zinc plates are placed in the water boxes and in the suction culvert for circulating water. The method adopted in the Harris-Anderson system consists in using aluminium plates supported from the tube plate in the water spaces at either end of the condenser. Aluminium, continues Major Cardew, is more strongly electro-positive than zinc to brass, and he suggests that aluminium plates should be tried instead of the zinc plates now being tried at Sydney, although it would be difficult to ensure a thorough metallic connection between the tubes and plates. Experiments are also being made with tinned and untinned tubes. Major Cardew favours the use of the latter, and suggests that they should be made of an alloy of 71·4 per cent. copper to 28·6 per cent. zinc. They should be connected to the tube plates by lead grommets.

Finally Major Cardew does not advise any further extension of the overhead extra high-tension conductors in Sydney, nor, unless under special circumstances, in the suburbs. In his opinion, the risks and losses inherent in this form of transmission more than outweigh the financial advantage.

"Cash Discount."—The National Electrical Manufacturers' Association is recommending that a universal practice be adopted of allowing "cash discount" to apply only up to the end of the month following the month in which the goods are despatched.

SUPPORTS FOR METAL FILAMENTS

Application for Revocation of a Patent abandoned

A FEW months ago application was made at the Patent Office for the revocation, under Section 27 of the new Patents Act, of patent No. 5,836/05, granted to L. Scholvien, of Berlin, and relating to supports for metal filaments. The patentee filed evidence in answer, and, after examining this, the applicant decided to abandon the application. The Comptroller has decided that in this and similar cases where no hearing takes place the name of the applicant shall not be made public.

The patent was applied for by L. Scholvien in March, 1905, but a previous application had been made in Germany in September, 1904. In the introduction of the specification it is pointed out that previous to the date of this invention metal filaments were arranged on a frame with several supporting arms, and that as this frame had to be introduced through the narrow neck of the bulb the arms were necessarily short, and the filament occupied a narrow cylindrical space. For this reason little light was emitted in an axial direction. The

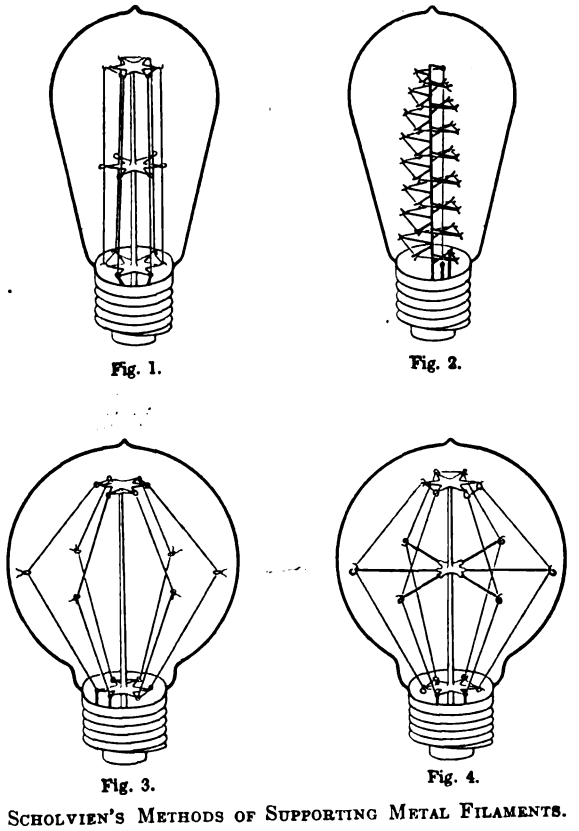

Fig. 1. Fig. 2.

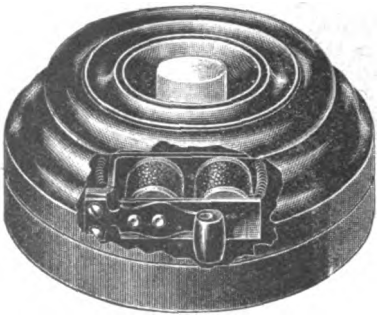
Fig. 3. Fig. 4.



SCHOLVIEN'S METHODS OF SUPPORTING METAL FILAMENTS.

supporting arms were also situated only at the ends of the cylindrical space, so that there was a tendency for the different sections of the filament to sag so much on becoming incandescent, that they touched. According to this invention, it was proposed to remedy these defects by providing additional supporting arms within the cylindrical space so as to shorten the unsupported lengths of filament, and by arranging the filament partly at an angle to the axis of the lamp so as to obtain a greater amount of light in that direction.

A method of arranging intermediate supports between the main supports according to the invention is shown in Fig. 1 of the specification. It will be noticed that all acute bends of the filament, which might cause short-circuits between the different sections of the filament, are avoided. A way of mounting a long filament so that the light is uniformly distributed, is shown in Fig. 2 of the specification, in which the intermediate supports are arranged in a helix. In Fig. 3, the intermediate supports are shown fixed to the wall of the bulb, and in Fig. 4 the filament is spread out by means of long flexible arms extending from the central pillar. In both the latter cases not only is the unsupported length of filament shortened, but the distribution of light is considerably improved, as the amount of filament throwing light in the axial direction is increased. In the lamp illustrated in Fig. 4 the long arms would be bent aside in order to introduce the frame into the bulb.

AN INDICATING BELL PUSH

THE accompanying illustration represents a form of bell push which the Sun Electrical Co. have recently introduced under the name of the "Bouverie" indicating bell push. The apparatus will be found useful in situations where the push is at a considerable distance from the bell, or for other reasons the bell cannot be heard by the person pressing the push, such as at front doors, &c. The illustration clearly shows the con-

struction of the push. A small buzzer is accommodated in the base, and connected in series with the line; so that the buzzer vibrates synchronously with the bell, giving a reliable indication of its working and also a warning when the batteries are becoming discharged, and the voltage has nearly dropped to a value at which the bell does not respond.

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, JUNE 10TH.

Royal Institution.

3 p.m. Afternoon Lecture II., by Prof. W. E. Dalby, on "A Modern Railway Problem: Steam *v.* Electricity."

FRIDAY, JUNE 11TH.

Physical Society.

8 p.m. Meeting at the Imperial College of Science, South Kensington. Among the Papers down for reading are the following:—(1) "The Arthur Wright Electrical Device for Evaluating Formulæ and Solving Equations," by Dr. A. Russell and A. Wright; (2) "The Proposed International Unit of Candle Power," by C. C. Paterson; (3) "Inductance and Resistance in Telephone and other Circuits," by J. W. Nicholson; (4) "Note on Terrestrial Magnetism," by G. W. Walker.

Royal Institution.

9 p.m. Evening Discourse on "Problems of Helium and Radium," by Prof. Sir James Dewar, F.R.S.

SATURDAY, JUNE 12TH.

Mining Institute of Scotland.

3.15 p.m. Meeting in the Oddfellows Hall, Kilmarnock. Among the Papers to be read are the following:—"Electrical Power Generation and Distribution at the Collieries of the Lochgelly Iron & Coal Co., Ltd., Fife."

MONDAY, JUNE 14TH.

National Electrical Contractors' Association.

6.30 for 7 p.m. Annual Dinner at Holborn Restaurant, London.

TUESDAY, JUNE 15TH.

Faraday Society.

8 p.m. Meeting at the Institution of Electrical Engineers, 92 Victoria Street, London, S.W. The following items are on the agenda:—Mr. E. R. Taylor, Chairman of the Conservation Committee of the American Electrochemical Society, will deliver an Address, illustrated with lantern slides, on "The National and International Conservation of Water for Power." The following Papers will be read:—"A Contribution to the Study of Electric Furnaces as applied to the Manufacture of Iron and Steel," by Ch. A. Keller; "Automatically Circulating Furnaces of the Gin Type for the Electrical Production of Steel," by Gustave Gin.

Telegraph Traffic.—Censorship on messages to Monte Christi, in Hayti, West Indies, was cancelled on the 3rd inst.; and on the 5th inst. the El Arich route was again working normally. On the following day the direct telegraphic communication between Saigon and Bangkok was restored to working order, as was also the *via* Fao route. An interruption of the cable between Cayenne and Salinas of the French Cable Company took place on the 7th inst. A break has also occurred in the lines of communication of the Indo-European Telegraph Company by the failure of the cable between Lowestoft and Emden.

Digitized by Google

LOCAL NOTES

ABERDEEN: *Tramway Receipts.*—The traffic receipts on the Corporation tramways during the year ended May 31st amounted to £70,744, against £71,078 for the preceding twelve months. The total receipts show a decrease of £254. Receipts per car mile work out to 10·9d., against 10·8d.

ALDERSHOT: *Electric Supply Profits.*—The accounts of the municipal electric supply undertaking for the year to March 31st last show a profit of £93, after meeting capital charges.

AUSTRALIA: *Sydney: Proposed Tube Railway.*—The Royal Commission which was appointed early last year to inquire and report upon the best method of establishing direct communication between the north and south of Sydney without interfering with the harbour has now reported. The Commissioners recommend the construction of a subway from side to side of the harbour for tramway traffic at an estimated cost of £460,000; a railway subway (tube railway) at an estimated cost of £753,000, and a vehicular subway at an estimated cost of £502,000.

BEXHILL: *Electricity Accounts.*—There was a net profit of £756 upon the working of the electricity undertaking for the year to March 31st. The revenue amounted to £9,754, against £9,700 in the previous year, and the total expenditure, exclusive of capital charges, was £5,113, against £5,249. Capital expenditure was £3,127. The total cost per unit has been reduced from 2·216d. to 2·19d.

BOLTON: *Tramway Intercommunication.*—A scheme of tramway intercommunication between the South Lancashire Tramway Co.'s system and that of the Corporation has been approved.

BOURNEMOUTH: *Tramway Accounts.*—A statement has been prepared which shows that there has been a loss of £5,416 upon the working of the Corporation tramways during the year to March 31st, 1909, after meeting capital charges. In order to improve the position, a scheme of rearrangement of the fares is to be put into force.

BRIGHTON: *Electricity Accounts.*—At the last meeting of the Corporation the accounts of the electricity undertaking, given in our issue for June 3rd, were approved. In presenting them to the Corporation, the Chairman of the Lighting Committee said the satisfactory result of the year's working was one which would have been reached before now but for circumstances over which they had no control, viz., the high price of coal and the repairs to the canal bank. In any event, the year's working had justified the transfer to Southwick. The two items upon which large savings were anticipated by generating all energy at Southwick were coal and wages, and notwithstanding a large increase in the output, the cost of both these items had decreased to a very large and satisfactory extent compared with the last year when all current was generated at North Road. This was in 1905, when the total works costs were 1·44d. per unit. Last year the costs were 0·79d. per unit.

BURNLEY: *Tramway Accounts.*—The accounts of the tramways department for the year to March 31st last show a net profit of £8,380, after meeting all capital charges, against £11,369 in the previous year. Of this sum £2,380 have been paid over to relief of rates, and the balance of £6,000 transferred to reserve fund. The number of passengers carried was 12,176,782, compared with 12,355,958 in the previous twelve months, whilst the car mileage increased from 1,202,330 in 1907–8 to 1,229,224 in 1908–9. Total receipts per car mile amounted to 12·22d., against 12·83d. in the previous year, and the working expenses to 7·99d., against 7·92d. Capital expenditure for the year amounted to £6,860, being a portion of the cost of new offices and a portion of the cost of five new top-covered cars now in course of erection.

BURY: *Electricity Accounts.*—During the year to March 31st the number of units sold by the Electricity Department was 1,593,757, against 1,440,659 for lighting and power purposes, and 3,217,360, against 3,004,403, for traction. The income of the undertaking was £16,733, and the expenditure, including capital charges, £13,819, leaving a net profit of £2,914. The gross profit was £8,990.

BUXTON: *Electricity Accounts.*—During the year to March 31st, 1909, the equivalent of 2,238 eight-c.p. lamps were connected. The net revenue for the year amounted to £6,157, and after meeting expenditure and capital charges, there is a deficit on the year's working of £2 16s., compared with a deficit of £278 in the previous year. The maximum load during the year was 330 kw. against 335 kw. in the previous year, a decrease due to the use of metal filament lamps. Total costs have been reduced from 2·04d. to 1·89d. per unit generated.

CALCUTTA: *Vibration from Electricity Works.*—Complaints are being made of nuisance by vibration from the works of the Calcutta Electric Supply Corporation, and the suggestion is being put forward that the Corporation should be forced to acquire all properties the owners of which claim to be affected. As the Indian Electricity Act was framed upon our own Electric Lighting Acts, supply authorities in India may find themselves in the position which several local authorities and companies here were a few years ago on the question, notably the St. Pancras Borough Council and the Isle of Wight Electric Light & Power Co. Both these authorities were forced to buy up adjacent properties at enhanced prices.

COLCHESTER: *Electricity Accounts.*—The electricity accounts for the year to March 31st show a net profit of £269. From this is deducted the deficiency of £24 on the previous year's working, and the balance is to be credited to depreciation. It has been decided to deduct from the depreciation fund the sum of £300, being plaintiffs' costs and expenses in the action brought by Messrs. Hollington Bros. in respect of nuisance from vibration at the electricity works, and £201 paid for consulting engineers' fees. The deductions will leave the sum of £1,605 to the credit of the depreciation fund.

Tramway Deficit.—There is a deficit of £3,939 on the working of the tramways undertaking for the year to March 31st. This is an increase of £1,011 over the deficit of the previous year. There was a decrease in revenue of £671, whilst the maintenance of overhead equipment, trolley wire, &c., has increased.

DARLINGTON: *Electricity Profits.*—At the meeting of the Corporation last week, the Chairman of the Electricity and Light Railways Committee stated that the Electrical Engineer objected to the proposed transfer to the rates of £2,000 from the profits of the electricity undertaking.

DUNDEE: *Electricity Accounts.*—The accounts of the electricity department show a gross profit of £12,047 for the year to March 31st last, against £9,741 in the previous year. After meeting capital charges, there is a balance of £1,256. There was an increase of revenue amounting to £2,000, and a decrease in the cost of coal of £2,650, notwithstanding the fact that 600,000 more units were generated. It is expected that the new generating station will be working by July.

EDINBURGH: *The Trackless Trolley System.*—The Tramway Committee, who have had under consideration the question of installing the trackless trolley system, have been in communication with the Midlothian County Council on the matter. The latter authority state that they are unable to express a definite opinion owing to the lack of experience with any system of this kind in Great Britain. At the same time it appeared probable that the use of such a mode of traction would entail considerable increase in the cost of maintenance of the roads, and might prove a considerable source of danger to the public using the roads.

ERDINGTON: *Tramways.*—The Board of Trade is to be asked to grant an extension of time until 1914 for the completion of the unconstructed works authorised by the Erdington Tramway Act, 1902.

FIFESHIRE: *New Tramway Scheme.*—A new tramway scheme is proposed for Western Fifeshire. The new line will run from the terminus of the Wemyss tramway system along the south coast of Fifeshire, by way of Aberdour and Inverkeithung to Dunfermline and on to Lochgelly, a distance of about 50 miles.

GLASGOW: *Tramway Receipts.*—For the year to May 30th, the receipts from the Corporation tramways amounted to £884,586, which is a reduction of £16,437 compared with the previous year. The number of passengers carried, viz., 220,618,183, is a decrease of 4,884,140.

HANDSWORTH: *Tramway Arbitration.*—Mr. Graham Harris is now sitting as arbitrator at the Westminster Palace Hotel to determine the price to be paid by the Urban District Council for the cable tramways in the district, now belonging to the Birmingham and Midland Tramways Joint Committee. The lines will eventually be leased to the company and converted to electric traction.

HESSLE: *Electric Supply.*—The Hull Corporation have informed the Council that whilst they would be willing to take a transfer of the Hessle electric lighting order, they could not reimburse the Council the cost of obtaining it. The undertaking in Hessle would be for the benefit of the ratepayers there, and, as there would be certainly a loss in the first few years, which Hull would have to bear, the Hull Corporation think that the cost of the order should remain with the Hessle Council. For the same reason, the Hull Corporation are not prepared to meet the cost of transferring the order.

KIRKCALDY: *Dysart Tram Extension.*—Terms have been arranged between the Corporation and the Dysart Town Council for the extension of the Kirkcaldy tramways to Dysart. The track will be single line with passing places.

LEEDS: *Trackless Trolley System.*—The report of the Sub-Committee which visited the Continent to inspect systems of railless traction has now been printed. The Committee recommend that such a system of traction should be adopted between the City and Farnley, instead of installing electric tramways, and that if necessary powers should be obtained to carry this into effect. The Committee, however, do not make any suggestion as to which system should be employed. They expressed the opinion that by means of adaptations and improvements, a system can be evolved which will serve the purpose of the Corporation. Whilst on the Continent the Committee inspected the Mercedes-Stoll system, which is in use in various parts of Aus-

Digitized by Google

tria; the Filovia system, which is in use in Northern Italy; and the Max Schiemann system, which is in use in Germany.

LINCOLN: *Electricity Accounts.*—The Corporation passed the accounts of the electricity department at the last meeting. The gross profit was £6,496, of which capital charges absorbed £3,974, the sum of £98 has been allocated to meet the deficiency on tramways, and £1,000 transferred to tramways risks insurance account, leaving a net profit of £1,424.

LLANDUDNO: *Tramways.*—The Llandudno & District Electric Tramway Co. is being urged to extend their line to Deganwy, but does not feel justified in doing so, as the line for two miles would pass through sandhills. An application, however, is to be made to the Light Railway Commissioners for a loan or grant, and the Councils concerned are supporting the application.

MAIDSTONE: *Charge for Tramway Energy.*—The price for energy for the tramways is to be reduced to 1½d. per unit.

MARKET HARBOROUGH: *Electric Lighting.*—The Board of Trade is to be asked to extend the time for carrying out the provisions of the Council's electric lighting Provisional Order.

MIDDLESBROUGH: *Meters.*—The Corporation has decided to meet expenditure on meters out of revenue in the future.

MORLEY: *Increased Charge for Lighting.*—After meeting capital charges there is a deficit of £1,799 upon the working of the electricity undertaking for the year to March 31st. In view of the almost universal use of metal filament lamps, the charge for current for lighting purposes has been increased from 4d. to 5d. per unit.

NOTTINGHAM: *Electricity Accounts.*—The accounts of the electricity department for the year to March 31st states that the number of units sold was 11,452,806, an increase of 335,971 over the previous year. No less than 52 per cent. of the lighting supply was at the rate of 1½d. per unit. The income was £93,836, and expenditure £47,322. After meeting capital charges, the sum of £17,250 is transferred to the rates, and £670 to the reserve fund.

Tramway Accounts.—The Tramways Committee report a decrease of £2,359, the number of passengers carried being 597,865 less than in the previous year. The total receipts amounted to £151,383, and after meeting working expenses, and capital charges, the committee are able to grant £15,400 in aid of rates, and to transfer £925 to reserve fund.

OULTON BROAD: *Electric Lighting.*—The Council last year was granted an electric lighting Provisional Order, but there seems some uncertainty as to what should be done with it. Inquiries are being made as to how other places of a similar size have dealt with electric lighting Provisional Orders.

PETERBOROUGH: *Price for Tramway Energy.*—Sir Alexander Binnie sat last week in London as arbitrator to determine the price to be paid to the Corporation for electrical energy by the Peterborough Tramway Co. Under the original agreement the company pay 2½d. per unit for the first 75,000 per annum, and 2d. per unit for the next 75,000 units, there being an obligation to take 150,000 units per annum. The present arbitration proceedings were held under the clause in the agreement providing for the revision of prices. The arbitrator's award has been reserved.

REIGATE: *Loan Refused.*—The Local Government Board have refused to sanction a loan of £2,340 which was recently applied for by the Corporation for electrical extensions. The reason given by the Board for their refusal has reference to the unsatisfactory financial position of the undertaking, a large loss on which has been incurred annually. The Board recommends the Corporation to call in an expert engineer to advise with regard to the undertaking generally.

RUNCORN: *Electric Lighting.*—The Castner Kellner Alkali Co., Ltd., propose to apply to the Board of Trade for a Provisional Electric Lighting Order for the Runcorn Rural District.

SOUTH AFRICA: *Durban: Electric Wiring.*—The Council has decided to wire premises on the hire-purchase system.

SOUTHAMPTON: *Additional Plant.*—The new boiler, for which an offer by Messrs. Babcock & Wilcox, Ltd., was recently accepted, is to be paid for out of revenue.

SWANSEA: *Electricity Profits.*—At the meeting of the Electric Lighting Committee on Thursday, some debate took place as to the disposal of the balance of £2,538 upon the electricity undertaking for the year to March 31st. It was pointed out that no depreciation fund exists, but the suggestion was made that the amount available should be shared between the rates and reserve. Eventually, however, the Committee decided to place the whole amount to reserve, in spite of a threat that an attempt will be made to reverse this decision when it comes before the Council.

WARRINGTON: *Electricity Accounts*—There was a decrease of current consumption of 1·98 per cent., or 51,903 units, during the year to March 31st, which is, however, principally due to the tramways, these having consumed 51,459 units less. The calls for lighting decreased by 32,250 units, but the power demand shows a small increase. The gross revenue amounted to £16,057, and working expenses to £9,318. Interest and sinking fund absorb £5,962, leaving a net profit, including bank interest, of £942, a decrease of £1,270 compared with the previous year. The number of units sold was 2,573,662.

WEDNESBURY: *Electricity Accounts.*—During 1908–9 the number of units sold was 223,708, compared with 176,406 in the previous year. The revenue amounted to £2,086, and expenditure to £1,648. Together with the balance brought forward, the sum now available is £634. Considering that the past year has been one of changing over from the company's bulk supply to the Council's own generating station, the committee regard the result as a very satisfactory one. The increase in the motors connected has more than trebled the output for this purpose, whilst the lighting connections have more than compensated for the reduction in old accounts due to the use of metal filament lamps.

WEYMOUTH: *Tramways.*—The Town Council is again considering the question of installing a tramway system. The matter was discussed for several hours on Thursday, but no decision was arrived at.

WORCESTER: *Electricity Accounts.*—The accounts of the electricity department for the year to March 31st show an income of £16,699. The total works costs amount to £6,863, and after meeting capital charges, there is a balance of £160, which has been transferred to appropriation account. The units sold show a slight increase, mainly due to the output of current for power purposes continuing to increase in a most satisfactory manner, an aggregate of 309 h.p. having been connected during the year. Works costs have been reduced from 0·889d. to 0·796d. per unit sold, whilst Mr. C. M. Shaw estimates that during the current year further economies can be effected which will bring the works costs down to 0·5d. per unit. The total costs last year were 1·011d. against 1·128d. per unit. Mr. Shaw recommends the installation of mechanical coal-handling plant and increased coal storage accommodation at the Hylton Road steam station at a cost of £650, from which expenditure he points to various savings and advantages.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

BELFAST.—Tenders are invited by the Corporation for feeder panels at the lighting switchboard of the power house. (See an advertisement on another page.)

BLACKBURN.—A loan of £18,000 is to be taken up in connection with the electric supply undertaking.

BOLTON.—An application is to be made to the Local Government Board for sanction to borrow £7,000 for the purposes of the electrical undertaking.

DARLINGTON.—A Local Government Board inquiry was held on Thursday into an application by the Corporation for sanction to borrow £3,900 for extensions to the electricity works. There was no opposition.

EASTBOURNE.—Quotations are to be obtained for a water-softening plant having a capacity of 1,000 gallons per hour.

ECCLES.—Tenders are invited by June 21st for the supply and erection of a water-softening and cooling plant having a capacity of 3,000 gallons per hour. Particulars from the Borough Electrical Engineer.

LEYTON.—A Local Government Board inquiry was held on Monday into an application by the Corporation for sanction to borrow £2,458 for the purposes of the electricity undertaking.

MAIDENHEAD.—A Local Government Board inquiry has been held into an application by the Corporation for sanction to borrow £3,500 for the purposes of the electricity undertaking.

MELBOURNE.—Tenders are invited by the Corporation for an overhead travelling crane. Particulars from Messrs. McIlwraith, McEacharn & Co., Ltd., Billiter Square Buildings, London, E.C., and tenders to the Chairman, Electric Supply Committee, Town Hall, Melbourne, by August 4th.

MIDDLESBROUGH.—The Corporation recently applied to the Local Government Board for sanction to borrow £10,000 for cable extensions. The engineer now reports that this amount has been overspent, and recommends that the proposed loan should be increased to £18,922, in order to provide for cable extensions during the next three years.

SALFORD.—Application is to be made to the Local Government Board for sanction to borrow £3,000 to cover the cost of extension of mains in the Prestwich district.

SOUTH AFRICA.—An expenditure of £13,000 is contemplated upon the East London Council's electricity works.

The Klerksdorp Council is considering the lighting of the town by electricity.

WATFORD.—The Local Government Board have sanctioned a loan of £4,952 for electrical extensions.

Miscellaneous

CANADA.—It is announced that engineers of the Ontario Hydro-Electric Commission will shortly be visiting Europe in connection with placing orders for motors, lamps, and other electrical apparatus.

An extension of the Fort William (Ontario) municipal electric tramways by seven miles is contemplated.

DEVONPORT.—Tenders are invited for (1) direct-current

Digitized by Google

meters; (2) paper-insulated cables, rubber-covered wires, flexibles and cut-outs; (3) lubricating oils. Particulars from the Borough Electrical Engineer, and tenders to the Town Clerk.

DUDLEY.—The Guardians invite tenders for the supply and erection of a 10-h.p. motor, with shafting and belting, in the workhouse laundry. Tenders to the Clerk by June 18th.

ITALY.—It is announced that the Genoa Council contemplate the erection of two electric elevators on the Caracciolo and Assereto bridges in Genoa harbour at an estimated cost of £120,000.

LONDON: *London County Council.*—The Council invite tenders for the roadwork and platelaying required for the authorised tramways in Southwark Street and Blackfriars Road, and on the Victoria Embankment east of John Carpenter Street. The routes are equivalent to about 1·1 mile of single track. The contractor will be required to use the track rails with their fastenings, the slot rails, and conductor rails, and the special work for the junction, cross-overs, &c., which will be provided by the Council, under other contracts, but all the remaining metal work and other materials will be included in the contract. Particulars from the Chief Engineer to the Council, and tenders to the Clerk by June 22nd.

Battersea.—The Lighting Committee have prepared a scheme for providing consumers with arc lamps and motors, and the wiring of premises on a cash purchase system or on the hire purchase system. The estimated cost is £1,500.

Hammersmith.—A loan of £2,000 is to be taken up to defray the cost of converting the system of street lighting from gas to electricity.

MAIDSTONE.—A recommendation by the Electricity Committee that 158 street gas lamps be converted to electric lamps has been adopted.

NETHERLANDS.—H.M. Consul at Amsterdam (Mr. W. A. Churchill) reports, says the *Board of Trade Journal*, that the Noord-Zuid-Hollandsche Tramweg Maatschappij is increasing its capital by an issue of £270,000 in bonds, for improvements and the electrification of the tramways. A copy of the prospectus of the company (in Dutch) concerning the issue of the loan, and giving particulars of the improvements and works contemplated, may be seen by British firms interested, on application at the Commercial Intelligence Branch of the Board of Trade.

RUSSIA.—An expenditure of about £94,000 has been sanctioned upon the municipal electricity works.

WAKEFIELD.—A Local Government Board inquiry was held on Thursday into an application by the Corporation for sanction to borrow £615, in respect of the purchase of transformers.

WHITEHAVEN.—The Harbour Commissioners invite tenders for lighting the harbour, quays, &c., by electricity, gas, or other means, for five years from January 1st, 1910. Particulars from the Harbour Master, and tenders to the Clerk by July 20th.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

N.—Shops (Golder's Green). Architect, J. Gibb, 88 West End Lane.

N.W.—Additions, Willesden Fine Art Co.'s premises. Builder, G. A. Sexton, Bank Chambers, Belsize Road, N.W.

N.E.—Additions to Eastern Hospital, The Grove, Homerton. Metropolitan Asylums Board, Victoria Embankment, E.C.

Additions to Homerton Workhouse. Architect, c/o City of London Guardians, 61 Bartholomew Close, E.C.

S.W.—Hospital, Merton Road, Merton, for the Trustees.

W.—Buildings at corner of Seymour Place and Upper George Street. Builders, J. H. St. John & Son, 44 Seymour Place, W.

PROVINCES.

BANGOR.—Hospital. Architect, Young & McKenzie, Scottish Buildings, Belfast.

CHATHAM.—Alterations and additions to Gaiety Theatre for H. E. Davis.

Baptist church, Sturla Road, for the Trustees of the Old Baptists.

DUBLIN.—Additions, St. Vincent Hospital. Architects, W. H. Byrne & Son, 20 Suffolk Street, Dublin.

DUNGIVEN (Ireland).—Presbyterian church (£1,000). Architect, S. Macartney, Dungiven. Builder, R. Colhoun, Strand, Londonderry.

EASTBOURNE.—Four houses and shops (£1,209). Architect, Carlos Cresford, 49 Gildredge Road, Eastbourne. Builder, E. Relf.

Public hall and winter gardens, Devonshire Park, for the Devonshire Park Co., Ltd.

GLASGOW.—Buildings for *Glasgow Herald*. Architects, J. Beaumont & Son, 10 St. James Street, Manchester.

GRIMSBY.—Catholic mission hall (£835). Architects, Bentley & Hall, Grimsby. Builders, H. W. Parker & Sons.

ILFORD.—Tenders are invited for wiring and fittings for about 200 16-c.p. lamps at the Goodmayes School, Ilford. Particulars from the Architect, and tenders by June 21st.

NEWCASTLE.—Drill hall. Architect, Graham & Hill, 133 Pilgrim Street, Newcastle.

NORTHAMPTON.—Additions to General Hospital, Billing Road, for the Governors.

SOUTH SHIELDS.—Skating rink. Architect, J. H. Morton, 5A King Street, South Shields.

TENDERS RECEIVED AND ACCEPTED

BOLTON.—The tender of Mr. R. J. Tyson, builder, has been accepted for the extension of the Duncan Street sub-station.

BUXTON.—The tender of the General Electric Co. for the supply of a commutator has been accepted at £5 15s.

DEWSBURY.—The tender of Messrs. Fox & Co., of Batley, has been accepted for electrical wiring of a new nurses' home at Dewsbury Workhouse Infirmary.

EDINBURGH.—The Corporation have placed an order with the British Thomson-Houston Co. for part of their yearly requirements in mercury meters (this meter was fully described and illustrated in our issue for February 18th, p. 157).

FARNWORTH.—The Council have accepted the tender of Messrs. Cowans, Ltd., for circuit-breakers, and that of the British Westinghouse Co. for cable.

GLASGOW.—The Corporation have placed an order with the British Thomson-Houston Co. for part of their yearly requirements in mercury meters.

LONDON: *Hackney.*—The Electricity Committee report having received tenders from ten firms (three foreign and seven British), for underground cables. The three lowest tenders would work out at the following prices for one year's supply:—Union Cable Co., Ltd., £3,288 17s. 0d.; Aubert Grenier & Co., £3,392 4s. 10d.; British Insulated and Helsby Cables, Ltd., £3,537 15s. 4d. Having considered all the circumstances, the Committee had decided to recommend the acceptance of the tender of the British Insulated and Helsby Cables, Ltd.

Ten firms tendered for the supply of joint boxes, frames and covers, and the following have been accepted:—British Insulated and Helsby Cables, Ltd., W. Lucy & Co., Ltd., Sykes & Sugden. The following tenders were also accepted, eleven firms having tendered:—British Electrical Trades Supply & Bitumen Co., Ltd., box compound; British Insulated & Helsby Cables, Ltd., resin; W. T. Henley's Telegraph Works, Ltd., linen tapes. The tender of the Sloan Electrical Co., Ltd., has been accepted for arc lamp carbons, and that of the General Electric Co., for yellow flame arc lamp carbons.

Hammersmith.—The Council have received the following tenders in connection with the electricity undertaking:—Supplying and fitting a coal conveyor and projector: Fraser & Chalmers (accepted), £660; Babcock & Wilcox, £880; H. Symon, Ltd., £1,198; Appleby's, Ltd., £1,440. Six high-tension automatic oil-break switches: Switchgear Co., Ltd., £8 14s. 6d. each; Spagnoletti, Ltd., £10; British Westinghouse Co., £12 12s.; General Electric Co., Ltd., £15 10s.; R. W. Blackwell and Co., Ltd., £16 2s.; Cowans, Ltd., £16 19s.

SALFORD.—The following tenders have been accepted for annual supplies for the Salford electricity undertaking:—Liverpool Electric Cable Co., Liverpool, rubber-covered cable; Electric and Ordnance Accessories Co., Ltd., switches and fuses; J. H. Tucker & Co., Birmingham, cut-outs; H. R. Mansfield, stoneware conduits; Albion Clay Co., stoneware conduits and pipes, cable protectors, and cable bearers; Key Engineering Co., fibre pipes; Howard Asphalte Troughing Co., asphalte bridges; Aubert Grenier & Co. and W. T. Glover & Co., cables; Veritys, motor starters; British Thomson-Houston Co., carbon filament lamps; L. Andrew & Co., Baxendale & Co., and W. T. Henley's Telegraph Works Co., cable accessories.

SHEFFIELD.—The Tramways Committee has accepted the tender of W. H. Allen, Son, and Co., Ltd., for the supply and erection at the Kelham Island Power Station of a surface condensing plant at £1,933. An order has been placed with W. T. Glover and Co., Ltd., for 50 tons of electrolytic copper wire, and 50 tons of lead, at the present current prices.

SWANSEA.—The tenders of the Electric Ordnance & Accessories Co., Ltd., for motors, and Messrs. Brook, Hirst & Co. for starting switches, have been accepted.

WARRINGTON.—The Council have accepted the tender of the St. Helens Cable Co., Ltd., at £692 3s. 9d., for cables.

YORK.—After considerable discussion the Corporation have decided to accept the tender of Messrs. Dick, Kerr & Co., Ltd., at £78,827 for the construction of the track and overhead equipment of the tramways. The work is to be completed within twelve months.

Central London Railway Bill.—This Bill was read a third time and passed in the House of Commons on Friday.

Digitized by Google

COMPANIES' MEETINGS AND REPORTS

NEWCASTLE-UPON-TYNE ELECTRIC SUPPLY CO.—At a meeting of first and second debenture holders recently a scheme for the issue of consolidated first mortgage debenture stock was approved. The new debenture stock will extinguish the present debentures either at once or at the end of 1911. In other words, existing debenture holders have a right either to accept the new stock or to maintain their present position, and to be paid off in 1911. New stock to the extent of £248,500 is also to be issued in order to bring the loan capital of the company up to £687,500. The difference between the two sums represents the conversion of the existing first and second debentures. At the meeting in question it was stated that during the first four months of the present year a sum sufficient to pay the interest on the new stock for the whole of the twelve months has been earned.

PERTH ELECTRIC TRAMWAYS CO.—At the meeting on Thursday, the report and accounts given in our last issue were adopted.

KALGOORLIE ELECTRIC TRAMWAYS CO.—At the meeting on Thursday the report and accounts were adopted. In order to carry out the policy of the Board to provide for renewals no dividend is paid this year, but as the profits for the first three months of the present year show an improvement upon those of the corresponding period of last year, the Chairman stated the Board looked forward to a better result for 1909.

ARON ELECTRICITY METER CO.—At the annual meeting on Tuesday the report and accounts given in our last issue were adopted. Mr. Hugo Hirst, chairman of the company, who presided, stated that the outlook was very reassuring, and that in the near future they hoped to reap the benefit of the large extensions which had been necessary to their works. New buildings were being added to their factories at Schneidnitz, and new premises were being built in Paris. Their electric clock business in Germany required additional capital.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £62 10s. to £63 (last week, £61 10s. to £62).

CALLENDER'S STAFF OUTING.—On Saturday, May 22nd, the head office staff of Messrs. Callender's Cable & Construction Co. held their third annual outing. This took the form of an excursion to Brighton, and a luncheon and tea at the Old Ship Hotel. Mr. T. O. Callender, the managing director, at the luncheon referred to the success which had attended the shorthand class, for which special facilities are granted by the firm, and also the newly formed swimming club.

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—Creditors of the Amalgamated Radio-Telegraph Co. are requested to send particulars of their claims to the liquidator, Mr. F. W. Pixley, 58 Coleman Street, London, E.C., not later than July 6th.

ELECTRICAL FOOTBALL LEAGUE.—The annual general meeting of the Electrical Football League was held on May 19th. After the balance sheet (showing a balance in hand of £2) had been adopted, applications were read from new clubs, amongst whom were City of London Electric and Poplar Borough Council. The matter was adjourned until the special general meeting, to be held shortly.

MISCELLANEOUS CITY NOTES

SAO PAULO TRAMWAY LIGHT & POWER CO.—A quarterly dividend of 2½ per cent. has been declared.

INDIA RUBBER, GUTTA PERCHA & TELEGRAPH WORKS CO.—An interim dividend of 5 per cent. per annum, free of tax, has been declared for the half-year to March 31st.

NEWCASTLE-ON-TYNE ELECTRIC SUPPLY CO.—Subscriptions are invited until to-day for £687,500 4½ per cent. consolidated first mortgage debenture stock. Particulars of the arrangements under which this issue is made are given in our "Companies' Meetings" column.

Electricity in Belgian Collieries.—According to the *Iron and Coal Trades Review*, a noticeable feature of the coal-mining industry in Belgium at the present time is the great development that is taking place as regards the adoption of electricity for both lighting and power purposes. One concern alone, the Société des Ateliers de Constructions Electriques de Charleroi, has during the past year established electric power generating plants at the pits of the Carabinier Company, and at the Kessales, Haine-St.-Pierre, Houssu, La Hestre, Courcelles-Nord, and Ormont Collieries. Electrically-operated winding engines have also been installed at the Baulet and Velaine pits of the Société Elizabeth, and at those of the Société des Houilleres d'Anderlues. The same concern is at present engaged in putting down electricity generating plants at seven other collieries in Belgium, the work in hand also including an electric winding engine for the Bascoup Colliery, which will be the largest in the country.

APPOINTMENTS AND PERSONAL NOTES

Mr. C. W. Thompson, consumers' engineer and canvasser to the West Hartlepool Corporation, has been appointed engineer and manager at the Saltburn electricity works. A successor is to be advertised for at a salary of £90 per annum.

Mr. A. H. Seabrook, who is retiring from the position of chief engineer and manager of the West Ham electricity undertaking to take up a similar post with the Marylebone Corporation, has been presented with a silver tea tray by the West Ham staff.

Mr. J. H. C. Brooking, manager of the Newcastle branch of Messrs. W. T. Glover & Co., Ltd., has been appointed General Manager of the St. Helens Cable Co., Ltd., Warrington.

Mr. G. J. Edwards, chief clerk and cashier in the Erith Corporation electricity supply and tramways department, has resigned, having obtained an appointment in Birmingham.

The recent recommendation of the Glasgow Watching & Lighting Committee that the salary of Mr. Langlands, inspector of lighting, should be increased from £350 to £400 per annum, has been rejected by the Corporation.

On Wednesday last, Mr. J. W. Beauchamp, Deputy Manager of the Sheffield Corporation Electric Supply Department, was the recipient of several articles of Sheffield plate subscribed for by the staff and employees as a token of esteem and goodwill, the occasion being Mr. Beauchamp's departure from Sheffield to Tunbridge Wells to take up the position of Resident Electrical Engineer. In making the presentation Mr. S. E. Fedden, the General Manager, referred to the good work Mr. Beauchamp had done during his eight-and-a-half years' service with the department, and, on behalf of the staff, congratulated him very heartily upon his appointment to a higher position, and wished him every possible success in his new undertaking.

NEW COMPANIES

ROBINSON & CARTER.—Registered, on May 5th, with a capital of £1,000, to carry on the business of electricians, engineers, manufacturers and workers of electricity, &c. The subscribers are R. Carter, 5 Thomas Street, Liverpool, electrical engineer; H. W. Robinson, 5 Thomas Street, Liverpool, electrical engineer. Private company. The number of directors is not to be less than two nor more than five; C. A. Robinson is permanent governing director. Remuneration as fixed by the company. Registered by T. T. Hull & Son, 22 Chancery Lane, W.C.

PROCKTER & KENYON.—Registered on May 7th, with a capital of £1,000 in £1 shares, to carry on the business of mechanical, electrical, and general engineers, iron, steel, and brassfounders, machinery brokers, makers and suppliers of electricity, &c. Private company. The first directors are C. Kenyon and F. M. Prockter. Registered office: Star Life Buildings, 30 Cross Street, Manchester.

STRATHPEFFER AND DINGWALL ELECTRIC CO.—Registered in Edinburgh on May 5th, with a capital of £100, to carry on at Strathpeffer and Dingwall the business of electricians, electrical and gas engineers, suppliers of electricity, &c. The number of directors is not to be more than three. Registered office: Kildary, Ross-shire.

DUAL IGNITION CO.—Registered on May 8th, with a capital of £100, to carry on the business of manufacturers of appliances for the electrical ignition of internal combustion engines, electricians, manufacturers, and warehousers of motors, motor and autocars, automobiles, auto-cycles, motor-boats, carriage builders, &c. Private company. Table "A" mainly applies. Registered office: Whitehall Chambers, 23 Colmore Row, Birmingham.

Institution of Mining Electrical Engineers.—We are asked to state that a general meeting of members and prospective members of the newly-formed Institution of Mining Electrical Engineers was held at Sheffield on Saturday, May 12th, under the Chairmanship of Mr. William Maurice, of Hucknall Torkard, the President of the Institution. Mr. Maurice suggested that branches should be formed in every mining centre, the position of each branch to be determined to suit the convenience of the majority of the members in each district. Each branch would be separately organised, with its President, Council, and Secretary, the Council being in proportion to the number of members. During the session of about six months each branch would hold meetings. All Papers submitted to be read at branch meetings would be first approved by the General Council, and then read so far as practicable, simultaneously at all the branches. The General Council would be mainly an organising and administrative body drawn from representatives of Local Councils. The General Council would hold quarterly meetings, and arrange for an annual general meeting, which, it was hoped, would be of a holiday character, in various mining centres. We published particulars of the formation of the South Wales branch in our issue of May 27th (page 487).

RECENT RESEARCHES IN WIRELESS TELEGRAPHY

PROF. J. A. FLEMING delivered a lecture on Friday evening before the Royal Institution on some of the most recent advances in the theory and practice of wireless telegraphy. After referring briefly to the methods that are being developed for using the antenna, both for transmitting and receiving without the necessity of switching over (see description of arrangement at the Bolt Head Station of the G.P.O. in ELECTRICAL ENGINEERING of December 17th, 1908, page 777), Prof. Fleming dealt with the lower balancing capacity. He recommended an insulated balancing capacity, consisting of a wire network supported above the ground, for antenna of moderate capacity only, but for long-distance work, he said, the network would become too large and impracticable, and so the earth must be used as the balancing capacity. This damps out the free oscillations in the antenna more quickly, but this effect can be compensated for by increasing the capacity of the antenna.

Speaking of the part played by the earth's surface in wireless telegraphy, the lecturer pointed out that if the surface is a good conductor, the electric wave hardly penetrates into it, but glides over the surface, but that if it is a poor conductor, the wave penetrates into it, going deeper the worse the conductivity. This is analogous to the skin effect in non-magnetic substances. In the case of sea water, an electric wave travelling over it penetrates only to the depth of a metre or two, but in the case of dry soil it goes much deeper, and a considerable absorption of the energy of the wave takes place, owing to the eddy currents set up by the horizontal magnetic lines, which are at right angles to the electric lines of force. Dr. Zenneck has shown mathematically that when a plane electric wave with a wave-length of 1,000 ft. is propagated over sea water, it would have to travel 10,000 km. before its amplitude would be reduced to 0·367 of its amplitude at the sending-station; over fairly dry soil, about 100 to 1,000 km.; and over very dry soil having a small dielectric constant, only about 1 to 10 km. This theory, said Prof. Fleming, is quite in accordance with practical experience, and the greater distances that can be worked to over sea are not merely due to the better earth that can be made at the stations. The reduction in the amplitude due to distance and proportional to the square of the distance traversed must, of course, be added to that due to absorption. Thus, if the earth absorption is such as to cut down the amplitude in the ratio of 1 : 0·367 at 1,000 km., then, at a distance of 3,000 km., the amplitude of a wave of 1,000-ft. wave-length would be cut down in the ratio of 3,000 to 1 by distance alone, but in the ratio of 60,000 to 1 by distance and terrestrial absorption combined. An increase of wave-length reduces the absorption by the earth. The reduction in wave-amplitude over dry soil is as much due to the small dielectric constant as to the high resistivity.

Turning to the transmitting apparatus, Prof. Fleming stated that if the condenser and antennæ circuits are closely coupled, the action and reaction of the circuits generates oscillations of two frequencies, and waves of two wave-lengths are radiated from the antenna. These waves have different damping and different maximum amplitudes. As the receiving antenna is generally tuned to one wave-length only, it has been the custom to employ only a loose or feeble inductive coupling between the coils of the oscillation transformer, so as to generate waves of one wave-length only. It is possible, however, to duplicate the receiving circuits and to capture the energy of both waves. An apparatus for creating feebly-damped oscillations of one wave-length has been developed by the Wireless Telegraph (Telefunken) Co., of Germany. This consists of a series of copper boxes cooled with water, the flat surfaces of which are placed in contiguity, but separated by very thin rings of mica. The spaces between the boxes are not more than $\frac{1}{125}$th of an inch, and 10 or 12 are placed in series. The row of boxes is connected to a transformer fed by a high-frequency alternator and to an oscillatory circuit. This produces 1,000 or more oscillatory discharges of the condenser per second, each of which has a large initial amplitude, but quickly dies out. The antenna hence receives a very large number of impulses per second, each of which sets up in it free electrical oscillations of one definite period. Prof. Fleming remarked that this discharger appears to operate on quite different principles from the single pair of discs with interposed paper ring employed by Von Lepel, which appears to act in the manner of the Poulsen arc. The Lepel system was described in ELECTRICAL ENGINEERING of May 13th, page 434.

The lecturer then briefly described the directive system developed by Messrs. Bellini and Tosi, full particulars of which were given in ELECTRICAL ENGINEERING of March 5th, 1908, Vol. III., page 348. Proceeding to discuss the problem of tuning, Prof. Fleming stated that the effectiveness of tuning depends on the form of the resonance curve. If this curve has a sharp peak, a slight want of tuning will greatly reduce the receiver current. To obtain sharp tuning, feebly damped oscillations must be employed, and also a receiving circuit in which there is little dissipation of energy by resistance and other causes. It is then possible to cause a change of even less than one-half of one per cent, in the wave-length of the received waves to cease to actuate the receiver. It is thus possible to distinguish between two waves 1,000 and 1,005 or 1,010 feet in length respectively, and a receiver may be tuned to respond to one and not to the other. The undamped oscillations created by the arc transmitters have an advantage in this respect over spark transmitters, in that the damping is less. A sending key can be used which does not interrupt the production of the waves, but simply alters the wave-length by about ¼ per cent. If the receiving station has a feebly-damped receiver, this change will be sufficient to cut up the telephone sound at that station into Morse dots and dashes. But another station not so tuned will either receive nothing at all or else a continuous unbroken sound.

Turning to receivers, the lecturer described the tantalum detector devised by Mr. L. H. Walter (see ELECTRICAL ENGINEERING of July 30th, 1908, Vol. IV., page 183), and then proceeded to discuss the sensitiveness of the telephone. To obtain the highest sensitiveness, the frequency of the actuating current should agree with the natural frequency of vibration of the telephone diaphragm, which is about 600 or 700 oscillations per second. Hence, alternators for large stations are now designed to give currents with a frequency of about 300 or 600 alternations per second, so that, when producing discharges of a condenser, the number of sparks per second may be at least 600. The lecturer then described the carborundum crystal detector. At a critical value of the pressure across a crystal, a slight increase or decrease in the applied voltage makes a large difference in the current passing, and further the conductivity of a crystal is different in different directions. Both these properties can be made use of, as a mass of crystals will rectify the trains of oscillations in the antenna, in the manner of an electric valve, or the same mass can be used at the critical voltage with a telephone. Prof. Fleming then mentioned various other forms of detectors, including his own, which depends on the variation in conductivity of an ionised gas at a certain critical pressure.

Finally, referring to wireless telephony, Prof. Fleming said that for this purpose the transmitting apparatus must be capable of producing uniform persistent oscillations of high voltage and frequency, not less than 30,000 or 40,000 per second, or at least above the limits of audition, and the amplitude of these oscillations must be capable of being varied by some form of speaking microphone placed in the oscillation circuit. No ordinary microphone will safely pass sufficient current for this purpose, but a type of multiple microphone has been used successfully.

Wireless Telegraphy and Telephony.—According to *The Times*, the Admiralty has elaborated a scheme for taking over wholly or in part the existing wireless stations on the coasts, and to establish others at other points. All stations will be maintained by naval ratings of the Fleet Reserve or Coastguard, but will be open for the receipt and despatch of private messages at the usual charges. Amongst the stations included is the De Forrest installation at Cullercoats, modifications being made in its equipment to enable interchange of messages with the Marconi system. Part of the scheme includes the manning of the stations by men of the Royal Naval Volunteers, and in order that the Volunteers may be trained for this work, the drill ships *Satellite* at North Shields and *Calliope* on the Upper Tyne will be equipped with wireless apparatus.

The Chinese telegraph administration in Shanghai is considering the establishment of wireless communication between the Altai Mountains and Ahsien in the north-west of Chinese Turkestan, as it would be practically impossible to erect a land-line across the great deserts owing to natural difficulties.

Trials of a new wireless telephone system, the invention of two French naval lieutenants, are being made off Toulon between the cruiser *Condé* and land stations. It is stated that speech has been transmitted over a distance of 60 miles.

The German military airship, *Gross II.*, ascended with wireless apparatus last week, and, it is said, succeeded in keeping up communication with a station below.

The new French wireless station at Mourillon is now in operation, and serves as a connecting link between the stations in the north of France and those in Africa.

The *Montreal Gazette* states that President Gomez of Cuba has issued a decree revoking the permission issued by President Palma in 1903 to Dr. Lee de Forrest to operate a wireless telegraph station at Havana. The reason given for this action is that the Government, having expended large sums to establish wireless communication, desires to maintain a monopoly.

THE PHYSICAL SOCIETY

AT a recent meeting of the Physical Society a Paper on

A Bifilar Vibration Galvanometer

was read by Mr. W. DUDDELL.

The Paper describes a new type of vibration galvanometer and a series of tests made upon it. Vibration galvanometers may be divided into two types: (1) those in which the moving part consists of a piece of iron and steel and the current to be measured flows round fixed coils as in the case of the Thomson galvanometer; (2) those in which the current to be measured flows round a moving coil placed in a fixed magnetic field on the syphon recorder principle. The vibration galvanometers of Max Wien and Rubens belong to the first class, while Mr. Campbell's vibration galvanometer and the one described in the Paper belong to the second. In the instrument described the mass of the moving parts is reduced to a minimum, the moving coil being reduced to the two wires forming its two sides, similar to a bifilar oscillograph, but with this difference: —Whereas the bifilar oscillograph is designed so as to make the damping aperiodic, the vibration galvanometer is designed so as to keep the damping as small as possible. A series of tests made upon the instrument showed that the total range of frequency was very large, namely, from about 90 cycles per second up to 1,900 cycles per second. The damping is very small, so that the resonance is very sharp. A series of measurements on the sensibility of the instrument showed that the sensibility to alternating current decreases very nearly inversely as the frequency for which the instrument is adjusted, whereas for direct current the sensibility decreases approximately inversely as the square of the frequency for which the instrument is adjusted, which is what usually takes place with direct-current galvanometers. The sensibility of the galvanometer for detecting small alternating voltages is reduced by the back E.M.F. of the instrument, and the Paper concludes with a determination of the magnitude of the back E.M.F. in the instrument shown at the meeting. The advantages of the galvanometer are its simplicity, ease in tuning, wide range of frequency for which it can be tuned, high sensibility, negligible self-induction and comparatively small back E.M.F.

A Paper by Messrs. W. P. FULLER and H. GRACE was also read on the

Effect of Temperature on the Hysteresis Loss in Iron in a rotating field.

The rotating field was produced by means of two-phase currents. One phase was connected to a coil of long rectangular section and of sufficient length to produce a uniform field within a radius of 2 cms. from the centre. The second phase was connected to a similar coil enclosing this one and causing a flux at right angles to it. The resultant field at the centre was uniformly rotating. An iron disc 4 cms. diam., 0·027 cm. thick, was supported by a bifilar suspension and the torque measured by a mirror and scale in the usual way. The specimen was heated by means of nickel wire heaters placed above and below it, and the temperature measured by means of a thermo-junction placed close to the disc. The flux in the iron was measured by the voltage induced in a coil of eight turns of bare wire wound round it. To measure the voltage, the maximum value of which was of the order of 0·03 R.M.S. volts, a special galvanometer was constructed. This depends for its action on the forces exerted by a rotating field on a suspended coil carrying alternating currents. If E be the E.M.F. applied to the moving coil, and E_1 the E.M.F. due to the field on the coil, then, by turning the coils producing the field round until the deflection is a minimum, this deflection is proportional to $E-E_1$. The results of the experiment show that the effect of increasing the temperature of iron is to reduce the hysteresis loss at a given induction and to cause the maximum loss to occur at a lower value of the induction. In one specimen the maximum value of the loss at 220° C. was 12,300 ergs per cu. cm. per cycle at an induction of 16,000 c.g.s. units. At 580° C. the maximum loss was 2,600 ergs at an induction of 10,700. The frequency of the experiments was 42 cycles per sec.

Dr. W. H. ECCLES remarked that the effects of previous thermal treatment, and of the nature of the material, were so enormous that comparison of the present experiments with similar ones with alternating fields was difficult; but the authors' curves seemed to show that the effect of rise of temperature on hysteresis loss was less for rotating fields than for alternating fields if the fields were below 12 c.g.s. The curves showed also that the maximum values of hysteresis loss in rotating fields were reached at lower and lower flux densities the higher the temperature, although the permeability varied but little. This was of importance from the point of view of the molecular theory of magnetism: it showed that smaller forces sufficed to rotate the molecules within a magnetically stable group at high than at low temperatures.

PROSECUTION OF TELEPHONE ENGINEERS IN ANTWERP

THE four telephone engineers, placed on trial at Antwerp on the charge of stealing trade secrets and documents belonging to the Bell Telephone Co., on their leaving that firm to take up engagements with the General Electric Co., have been acquitted. We published particulars of the charges made against them in our last issue (p. 508). The hearing of the evidence occupied the court from May 27th to 29th, and on Wednesday last week counsel's speeches were heard. After twenty minutes' deliberation the court returned a verdict of acquittal against all four of the accused, and the Bell Telephone Co. was ordered to pay costs.

CATALOGUES AND PAMPHLETS, &c., RECEIVED

[*Readers applying to any of the under-mentioned firms for copies of the catalogues or pamphlets referred to are requested to mention "Electrical Engineering."*]

FITTINGS.—A handsomely-produced catalogue from Messrs. Julius Sax & Co., Ltd., gives particulars of a series of new fittings specially designed for use with holophane glassware. These well-known shades and globes are specially suited to the larger sizes of metal filament lamps, the high intrinsic brilliancy of which necessitates a good diffusion of the light. The fittings designed by Messrs. Sax enable full advantage to be taken of the efficient way in which this can be obtained by holophane ware, while at the same time a most artistic effect is produced. A light is obtained which will compare very favourably with an enclosed arc lamp as regards quality, and closely approximate if not actually equal it for efficiency without the attendant trouble, with a fitting which will harmonise with the style of the building and decoration.

SHADES AND FITTINGS.—A leaflet from Messrs. Siemens Brothers Dynamo Works, Ltd. (Tyssen Street, Dalston, N.E.), contains particulars of a number of new designs of shades for tantalum and other lamps, including specially long shades of graceful proportions for high-voltage lamps. Another leaflet illustrates some further designs of majolica fittings for tantalum lamps suitable for ship lighting, restaurants, theatres, corridors, &c.

ELECTRIC MOTORS.—Messrs. Stephan & Co., of St. John's House, 124 Minories, who are sole representatives for the United Kingdom and the Colonies of the Conz Electrical Co., Ltd., of Hamburg, have sent us a leaflet calling attention to the quality, workmanship, and high efficiency of their dynamos, motors, rotary convertors, and accessories. Mr. E. Bergström, Manager of Messrs. Stephan & Co., informs us that he will be pleased to answer inquiries, or to forward catalogues of any particular class of machine, and that his representative can call by appointment upon any firm desiring additional information.

WIRELESS TELEGRAPHY.—We have received from the London Telegraph Training College (29 Penywern Road, Earl's Court, S.W.), a copy of a reprint of an article on "Wireless Telegraphy on Board Ship," by Mr. M. Child, lecturer and demonstrator to the Wireless Telegraph Department of the College.

FEED WATER HEATING.—We have received a new catalogue of apparatus for the Hudson economiser system of feed water heating from the Hudson Economiser Co. (2 Bishopsgate Street Without, E.C.). The Hudson patent combined feed heater and oil separator is described and illustrated, as well as a form of internal live steam feed water heater for Lancashire and similar boilers. The Hudson Separator contains two compartments set one above the other. The oil falls by gravity from the upper, or separating, chamber into the lower, whence it may be withdrawn by a special pump, driven by motor, steam engine, or belt. The pump is so constructed that it will extract the oil even against a vacuum.

NATIONAL ELECTRICAL MANUFACTURERS' ASSOCIATION.—We have received from Mr. F. B. O. Hawes, Secretary to the National Electrical Manufacturers' Association (Incorporated), Balfour House, Finsbury Pavement, London, E.C., an advance copy of a pamphlet setting forth the objects of the Association and the work that it has already accomplished. Reference is made to this in an editorial note on p. 522. All electrical manufacturers who are not already members of the Association should write to Mr. Hawes for a copy of this pamphlet.

East London Railway.—The *Financial Times* learns on very good authority that there is good foundation for the recent reports as to the pending electrification of the East London Railway.

Rand Electric Power Companies.—The Transvaal Government have appointed a Commission to inquire into the desirability of the establishment of large electric power companies in the Transvaal, and the probable effect of such companies on the Witwatersrand gold industry, the coal industry, the Central South African Railways, agriculture and irrigation, the employment of labour, &c.; also into the attitude of the State to such companies.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published June 3rd, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

15,215/08. **Mercury Motor Meters.** G. HOOKHAM. In meters of this type it is necessary that the mercury should be in intimate contact with the metal armature, and it has been usual to coat the latter with a film of platinum, and finally a film of a readily amalgamated metal, such as silver or copper. This outer film, however, has not proved satisfactory, as it easily comes off. According to this invention, a thin film of palladium is used over the platinum covering or direct on the metal armature. This readily amalgamates and lasts a long time. Such a film of palladium may also be applied to the contacts of mercury switches and other apparatus where intimate contact between mercury and any other material is required. It will adhere to carbon or insulating material. Three claims.

15,664/08. **Polyphase Relay.** ALLGEMEINE ELEKTRICITÄTS GES. A relay for a three-phase circuit consists of a closed field ring with three polar projections, each wound with a coil in a different phase. The armature has three poles corresponding to the three field poles, and three intermediate poles, so as to form a magnetic circuit of low reluctance for each coil. It is set unsymmetrical, and, on the occurrence of a short-circuit, earth, or overload, tends to take up a symmetrical position. In doing so, it pushes a weighted lever over its dead centre, and this falls and closes the trip-coil circuit of the circuit-breaker. When used as a no-voltage relay, the armature is set in the symmetrical position, and falls into the unsymmetrical position, pushing over the weighted lever, when the coils are de-energised. Three claims, five figures.

17,412/08. **Insulation of Switch Contacts.** SIEMENS BROS. DYNAMO WORKS, LTD., and E. G. NICHOLLS. When fixing contact studs to metal bases, it has been usual to insulate each stud and its fixing-bolt by means of micanite washers and an insulating sleeve respectively. According to this invention, one or more slots are cut or cast in the base, and a thick micanite plate is fixed over these. The studs are then bolted direct to the micanite plate. A motor-starter with a row of contacts fixed on a single micanite plate over a long slot in the base is shown in the specification. Two claims, two figures.

23,185/08. **Meat-curing Process.** A. J. BOVIT (*Electric Meat-curing Co., U.S.A.*). Passing current through brine in which meat is being cured considerably shortens the time necessary for curing, and gives improved results generally; heating or electrolysis of the brine must be avoided, however. According to this invention, the brine is continuously circulated and passed through a cooling-tank, and, to avoid contamination due to the products of electrolysis, the electrodes are enclosed in porous pots, and the current reversed at intervals. Electrolysis would be avoided by using alternating current, but the above method is said to give better results. Seven claims, two figures.

27,097/08. **Insulation of Fine Wires.** SIEMENS-SCHUCKERTWERKE-GES. Fine wire is covered with a thin layer of silk or cotton, and, after being wound on bobbins, is placed in a heated vacuum chamber. An adhesive insulating varnish is then admitted into the chamber. This hardens on drying, and effectually fastens the covering to the wire. One claim.

Opposition to Grant of Patents

23,280/07. **Protection of Cable Systems.** C. C. GARRARD and FERRANTI, LTD. A grant has been allowed on this application in spite of opposition. The patent relates especially to the protection of interconnecting feeders on the balanced system, the feeder being disconnected automatically when current flows through different parts in different directions. Reverse-current relays arranged at each end of the feeder make or break contacts in series with the trip-coil circuit. Under normal conditions a make at one relay occurs with a break at the other, and the trip-coil circuit remains broken. On a fault occurring, both relays make contact and the trip-coil circuit is closed, causing the feeder to be disconnected. The trip-coil current is superposed on the feeder current when the feeder is connected to transformers at each end, and can be taken from a battery. No pilot cable is then required. If the protected feeder is directly connected to the system, a separate pilot cable must be used for the trip-coil current.

19,311/08. **Manufacture of Tungsten Filaments.** SIEMENS & HALSKE AKT.-GES. In spite of opposition, a patent has been granted on this application. The process described consists in first reducing a mixture of nickel tungstate and tungstic acid, so that an intimate and ductile mixture of nickel and tungsten is obtained. This is rolled and drawn into filaments, the nickel being afterwards removed by heating in a vacuum. Further particulars were given in ELECTRICAL ENGINEERING of Jan. 1st, 1909, page 21.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: COHEN, CRAMER, and GEIPEL [Manufacture of Cables] 10,535/08; ISAAC [Identification of cables] 7,298/09.

Dynamos, Motors, and Transformers: SIEMENS BROS. DYNAMO WORKS and KLOSS [Machines] 14,049/08; BRITISH THOMSON-HOUSTON Co. (*General Electric Co., U.S.A.*) [Slip-rings] 17,380/08; SIEMENS BROS. DYNAMO WORKS (*Siemens Schuckertwerke-Ges.*) [Parallel running of A.C. generators] 18,715/08.

Electric Ignition: DARRAH and PERRINS [Ignition of miners' lamps] 12,286/08; THOMPSON (*Ernst Eisemann & Co. Ges.*) [Ignition apparatus] 27,999/08.

Electrometallurgy and Electrochemistry: PHILLIPS (*Meaker Co.*) [Electroplating apparatus] 5,087/09; SALPETERSÄURE INDUSTRIE-GES. [Arc furnaces for treatment of gases] 8,443/09.

Incandescent Lamps: WOLFRAM LAMPEN AKT.-GES. [Filaments] 10,891/03; COOLIDGE [Filaments] 17,621/08; KROLL and SAKLATWALLA [Filaments] 27,144/08.

Instruments and Meters: HIBBERD [Coin-freed meters] 8,438/08; GALLAGHER [Statement delivery apparatus for meters] 23,348/08.

Storage Batteries: NEW IGNITION SYNDICATE and SANDY [Electrolyte] 10,520/08; VOGEL [Plates] 14,814/08.

Switchgear, Fuses, and Fittings: BRITISH THOMSON-HOUSTON Co. (*General Electric Co., U.S.A.*) [Regulating devices] 14,701/08; WEISSMAN [System of fitting lamps] 18,233/08.

Telephony and Telegraphy: KINGSBURY (*Western Electric Co.*) [Retransmitting and reinforcing telephone currents] 17,047/08.

Traction: BARNETT [Signalling] 3,501/08; SCOTT [Suspension of trolley wires] 19,621/08; JONES and EVANS [Emergency brake] 24,766/08; JUSTICE (*Essex Co.*) [Third-rail insulators] 27,477/08.

Miscellaneous: BERRY [Electric power hammers] 10,539/08; ANDERS [Electric clocks] 10,626/08 and 10,627/08; BROOKS and ALSTON [Induction coils] 11,170/08; LIGHTFOOT [Safety device for portable hand lamps] 19,679/08; WARTMANN [Electro-medical treatment] 27,512/08; DICKSON [Advertising device] 28,135/08.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

KUZEL [Metal filament lamp] 25,044/08; WHITE [Motor control] 6,567/09; ALLGEMEINE ELEKTRICITÄTS-GES. [Power transmission systems] 11,339/09 and 11,400/09; HIORTH and SODERBERG [Induction furnaces] 11,480/09; SIEMENS SCHUCKERTWERKE-GES. [Meters] 11,634/09.

Expiring and Expired Patents

The following Patents expire during the current week after a life of fourteen years:—

11,482 of June 12th, 1895. **Telegraphy.** H. A. TAYLOR and J. A. L. DEARLOVE. Repeating mechanism for submarine working, in which a clockwork transmitting apparatus relays the signals on to the second section of the line.

11,543 and 11,549 of June 13th, 1895. **Indicating Lamps in Telephone Exchanges.** J. E. KINGSBURY (*Western Electric Co., U.S.A.*). Two important patents covering the connection of lamps on telephone switchboards for use as calling and clearing signals.

The following are the more important Patents that have become void through non-payment of renewal fees.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: C. J. KRONENBERG [Arms and insulator-pins for line poles] 3,492/00.

Dynamos, Motors, and Transformers: J. F. MCELROY [Train-lighting system] 3,620/03 and 3,620A/03.

Electrometallurgy and Electrochemistry: H. H. LAKE (*Soc. Anon. "Le Carbone"*) [Primary cell] 4,254/02 and 4,274/02; W. A. SHENSTONE [Furnace for glass manufacture] 4,031/03.

Switchgear, Fuses, and Fittings: F. PALM [Lamp caps and sockets for fixing lamps direct on bare conductors] 3,841/98; T. SUTCLIFFE [Ceiling roses] 3,758/03; A. G. BROOKES (*H. D. Betts and R. M. Thomas*) [Conduit fittings] 3,939/03; J. KLINKENBERG [Left control gear] 3,840/04.

Telephony and Telegraphy: L. M. ERICSSON [Telephone system with automatic sub-exchanges] 3,591/99; M. BYNG and F. G. PELL [Direct-call telephone and fire-alarm systems] 3,441/00; L. DE FOREST [Tuning in wireless telegraphy] 3,876/03.

Traction: M. CATTORI [Track in insulated sections made live by passing car] 4,176/98; W. KINGSLAND [Car tappets for operating switches on track] 3,487/01.

"Electrical Engineering," although the Cheapest Electrical Paper (Price 1d. weekly), contains the Most Useful and Practical Articles, the Best Illustrations, and the Latest News. It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.

SUMMARY

As the result of a man having been killed by receiving a shock from a charged trolley standard, it is probable that the Board of Trade will shortly issue a regulation to the effect that the circuit to warn the driver or conductor of a trolley standard being live should be tested periodically. In this case it appears that there was a break in the circuit of the red warning lamps. The Board of Trade expresses its decided preference for an audible signal in place of the usual red lamps. (Page 547.)

A SERIOUS explosion, due to a faulty service joint, occurred in Manchester on Monday morning. According to the official account, the fusion of the cables at the joint melted the bitumen in which they were laid and resulted in an explosion. Some adjacent gas pipes were also fused. (Page 547.)

THE members of the Metropolitan Association of Electric Tramways Managers paid a visit on Friday to the Metropolitan Electric Tramways. (Page 548.)

GENERAL matters of trade and general interest were referred to at the annual dinner of the Electrical Contractors' Association on Monday, including the municipal wiring clause in the Electric Lighting Amendment Bill, the rebate given to the E.C.A. by the Cable Makers' Association, and the intentions of the Institution of Electrical Engineers with regard to examinations, wiring rules, and etiquette. (Page 548.)

THE fourteenth Annual Convention of the Incorporated Municipal Electrical Association will be held in Manchester from Monday to Friday next under the presidency of Mr. S. L. Pearce, Chief Electrical Engineer to the Manchester Corporation. We publish portraits and biographical notes of the President and the readers of Papers, and descriptions of the various works that will be visited. At the Manchester Corporation electricity works the new 6,000 kw. Willans-Siemens turbo-alternator, with its auxiliary ventilating plant, will be the feature of interest, and at Liverpool, which will be visited on Wednesday, a fine set of vertical Curtis turbo-alternators will be seen at Lister Drive station. A visit to the "Mauretania" will afterwards be paid. A tour of the vast works of the British Westinghouse Company will be made on

Digitized by Google

Thursday, and at the electricity works of the Salford Corporation on Friday a Willans-Brown-Boveri continuous-current turbo-generator will be seen, as well as older reciprocating plant. The works of the Lancashire Electric Power Co. at Radcliffe will also be open to inspection on the same day. In addition to these, the following will be available as alternative visits:—Lancashire Dynamo & Motor Co.'s works; Electromotors, Ltd., works; Hyde Road car shed of the Manchester Tramways Department; Manchester Municipal School of Technology; Polygon Sub-station and Testing Department of the Manchester Corporation; Messrs. Connolly Bros.' works, Blackley; and the generating stations of the Bolton, Bury, and Oldham Corporations. (Pages 549 to 555.)

A LIST of all the members who have signified their intention of attending the meeting will be found on pages 555 and 556.

AN application is to be made to the Board of Trade by the Bath Corporation for an order stating that the powers of the Somerset & District Electric Power Co. in Bath shall cease.—The Electrical Engineer to the Gillingham Council has reported at length upon tenders for a Diesel engine generating set, the installation of which he recommends in preference to taking power in bulk at 0·875d. per unit.—The working expenses on the Lincoln surface-contact tramways for the past year were 5.60d. per car mile, against 6.37d. per car mile, which is the average for 75 municipal overhead systems.—Motors are to be loaned to prospective consumers by the St. Pancras Council in order to enable a comparison of working costs to be made.—The maximum demand system of charging is to be abandoned at Torquay.—A net profit of £1,938 is shown by the Eastbourne Corporation electricity accounts for the past year.—The Leeds Corporation have adopted the recommendations of the Tramways Committee to instal the trackless trolley system in Farnley. (Page 557.)

A LANCASHIRE boiler is required at Bedford; cables at Brighton and Bristol; a generating set and condensing plant, boiler, &c., at Burslem; cooling tank, &c., at Felixstowe; an automatic stoker at Gravesend; and a coal conveying plant at Wolverhampton.—A number of local authorities propose to apply to the Local Government Board for loans. (Page 558.)

A 2½ per cent. dividend is recommended on the preferred shares of the Birmingham & Midland Tramways for 1908.—A 2 per cent. dividend is recommended upon the ordinary shares of the Yorkshire (Woollen district) Tramways Co. (Page 560.)

WE describe in detail the construction and working of the new "Flamgold" double-carbon gravity-feed flame arc lamp. The two pairs of carbons are burnt alternately, the arc changing over every 15 to 20 minutes. Interesting features of the lamp are the bell-shaped brass economiser and the magnets for the control of the arc. A 9-amp. D.C. lamp burns for 20 hours on one trimming, and an A.C. lamp for 18 hours. (Page 561.)

A NEW electrically-operated self-contained clock will shortly be put on the market. A balance wheel controlled by an isochronic spring is given an impulse every three seconds by means of an electromagnet on the wheel, and the movement is transmitted direct to the seconds hand. (Page 563.)

A PROPOSAL by the Institute of Municipal Treasurers and Accountants (Incorporated) to re-arrange the financial control and management of the municipalities throughout the United Kingdom, has been vigorously opposed by the Incorporated Municipal Electrical Association and the Municipal Tramways Association. (Page 563.)

A NEW form of trolley has been tested on the Cologne tramcars, in which the wheel is double-conical in shape, and has two spiral grooves leading up to a running groove in the centre. Rigid side arms to prevent the wire leaving the wheel laterally are provided, and the spiral grooves lead the trolley to the centre of the wire, when it is displaced on curves, &c. (Page 565.)

IN his second lecture on Steam v. Electric Traction, before the Royal Institution on Thursday, Prof. W. E. Dalby indicated how the horse-power of a steam locomotive for a given service was determined, and gave some corresponding notes referring to electric locomotives. He then illustrated the effect of frequent stops on the energy consumption. (Page 565.)

MR. HAYDN HARRISON writes commenting on the tests of the experimental street lighting at Bradford, reported in our last two issues, and points out some advantages of comparatively small units, such as can be obtained by the use of metal filament lamps, over arc lamps, for street lighting. A letter from Mr. W. P. Durtnall urges the view that internal combustion engines with electrical transmission have a possible field of use for railway work. (Page 567.)

THE Unopposed Committee of the House of Commons has refused the electric power companies on the North-East coast authority to invest a portion of their funds in other industrial concerns in order to encourage the use of electricity. (Page 567.)

AMONG the specifications published by the Patent Office on Thursday was one relating to the manufacture of "Liconite" cables and insulating materials, some tests on which were described in our columns last year. There were three interesting patents for processes of manufacturing metal filaments; in one of these processes the binding agent is squirted round the tungsten powder core instead of being intimately mixed with it. The Salpetersäure Industrie Ges. have patented an arc furnace for the oxidation of atmospheric nitrogen, in which there are several air inlets and gas outlets along the tubular arc-chamber. The opposition to the grant of two patents relating to ignition apparatus for miners' lamps and galvanising apparatus respectively, has been unsuccessful. A patent by L. Mond for the electrolytic reduction of metallic oxides, and another by H. J. Voigt and J. A. Haeffner for metal film resistances, expire during the current week. (Page 568.)

NEXT week will be a busy one for members of the Incorporated Municipal Electrical Association meeting at Manchester. The subjects chosen for Papers and discussions cover a wide field, and the visits which have been arranged offer a selection that may be made to suit every taste. The visit to the "Mauretania" at Liverpool, kindly permitted by the directors of the Cunard Steamship Co., Ltd., will be a very pleasant variation from the usual routine of visits to stations, car-sheds, and manufacturing works; the majority of the members who have not been on an Atlantic liner before will find matters not connected with electrical engineering to interest them, whilst at the same time the electrical equipment is of considerable magnitude, and possesses much that is worthy of minute inspection. The other visits afford an opportunity for the examination of specimens of almost every system of electricity supply. As to the Papers, practically the only subjects not touched upon are boiler plant and traction. The former has been so fully discussed at recent meetings that its omission from the programme this time is natural, but it is a matter for regret that tramway matters are once again to be neglected, and

Digitized by Google

left entirely to the tramways association. This, however, detracts only slightly from the value of the present meeting, and it may be safely prophesied that the Fourteenth Annual Convention of the Incorporated Municipal Electrical Association will be a great success both in its technical and social aspects. Our list of gentlemen who have announced their intention of attending the meeting includes 285 names, as compared with 181 last year.

ARRANGEMENTS FOR THE WEEK

MONDAY, JUNE 21ST.

Incorporated Municipal Electrical Association.

7.30 p.m. Fourteenth Annual Convention at Manchester. Reception and Conversazione at the Town Hall.

TUESDAY, JUNE 22ND.

Incorporated Municipal Electrical Association.

10.30 a.m. Meeting at the Manchester Municipal School of Technology, Whitworth Street, when Mr. S. L. Pearce will deliver his Presidental Address. The following Paper will then be read: "Cheap Units," by Councillor A. Sinclair (Swansea).

2.45 p.m. Visits to the Stuart Street, Dickinson Street, and Bloom Street generating stations of the Manchester Corporation.

WEDNESDAY, JUNE 23RD.

Incorporated Municipal Electrical Association.

10 a.m. Meeting at St. George's Hall, Liverpool. Papers to be read: (1) "The Influence of Metallic Filament Lamps on the Electrical Industry and on Street Lighting," by E. E. Hoadley (Maidstone); (2) "Modern Cable Systems," by E. M. Hollingsworth (St. Helens).

2.30 p.m. Visit to Lister Drive Power Station of the Liverpool Corporation.

4.30 p.m. Visit to R.M.S. "Mauretania."

"*Dynamicables.*"

7 for 7.30 p.m. Dinner at the Trocadero Restaurant.

THURSDAY, JUNE 24TH.

Incorporated Municipal Electrical Association.

10 a.m. Meeting at the Manchester Municipal School of Technology, Whitworth Street. Papers to be read: (1) "Steam Turbines from the User's Point of View," by A. S. Blackman (Sunderland); (2) "Notes on Condensing and Water Cooling Plants," by E. Lunn (Huddersfield).

2.30 p.m. Visit to the Westinghouse Co.'s Works.

6.30 for 7 p.m. Annual Dinner at the Midland Hotel.

FRIDAY, JUNE 25TH.

Incorporated Municipal Electrical Association.

10.30 a.m. Annual General Meeting at the Manchester Municipal School of Technology, Whitworth Street, for the election of Council and Officers for the 1909-10 Session.

2.30 p.m. Visit to the Frederick Road power station of the Salford Corporation.

Physical Society.

5 p.m. Meeting at the Imperial College of Science, Imperial Institute Road, South Kensington. The following are among the Papers to be read: (1) "On the Measurement of Wave Length for High-frequency Electrical Oscillations," by A. Campbell; (2) "An Electro-magnetic Method of Studying the Theory of and Solving Algebraical Equations of any Degree," by A. Russell and J. N. Alty; (3) "An Instrument for Measuring the Strength of an Intense Horizontal Magnetic Field," by F. W. Jordan.

Wireless Telegraphy and Telephony.—Another example of the importance of wireless telegraphy on ocean-going steamers is afforded by the case of the Cunard liner *Slavonia*, wrecked off Flores, in the Azores, last week. Both the North German liner *Princess Irene* and the *Batavia* left their normal course, and went to take off the 600 passengers of the *Slavonia*, having received her signals of distress and particulars of her position by wireless.

Wireless stations are to be installed at Susitna and Seward, Alaska, and the Chinese Board of Communications is inviting, through the telegraph administration in Shanghai, tenders for erecting wireless stations for communication between the Altai Mountains and Ahsien, in the north-west of Chinese Turkestan.

Another wireless station has been erected in Trinidad, a little over three miles from San Fernando. The mast is 225 ft. high. This station is the property of the West India & Panama Telegraph Co., and Mr. Blenheim, the expert for the company, is now engaged in fitting it up. It is to be ready this week. A description of the Government station at Trinidad was given in ELECTRICAL ENGINEERING of August 20th, 1908, page 281.

TRAMWAY STANDARD ACCIDENT

ACCORDING to the Board of Trade regulations, the trolley standard on every double-deck car must either be earthed to the wheels of the car, or must be so connected that it gives "a distinctive or continuous warning signal to the driver or conductor" if it becomes electrically charged. The latter practice is usually followed, and a red lamp is used as the signal, but in the latest Board of Trade regulations it is stated that the signal "may be a red lamp or, preferably, an audible signal." The regulation is obviously a necessary one, for if a fault develops which puts the trolley standard in connection with the trolley and trolley wire, any passenger might receive a 500-volt shock between the standard and the rail on the top deck of the tramcar which is earthed.

Recorded cases of shock received in such a manner have been extremely rare. A few weeks ago a tramcar driver off duty, when travelling as a passenger, managed to receive such a shock, and obtained damages from the West Ham Corporation. Only one fatal case has occurred, however; on May 21st a blast-furnace-man, who was standing on a car in a peculiar position, with one foot on the trolley standard, and his back (or, according to one witness, his head) against the hand railing on a car belonging to the Wolverhampton District Electric Tramways, Ltd., received a shock which killed him.

The inquest was adjourned until Friday last week in order that Mr. A. P. Trotter, the Electrical Adviser to the Board of Trade, might be communicated with. From the evidence given, and from Mr. Trotter's investigations, it appeared that there was a break in the circuit of the warning red lamps, so that the driver and conductor did not know that the trolley standard was charged.

As a result of the accident, we have reason to believe that a Board of Trade regulation may shortly be issued making it obligatory on the tramway authorities to make periodical tests of the warning circuits to the trolley standard. Mr. Trotter is also very much in favour of a bell signal being employed instead of the customary red lamp, and in all probability the majority of tramway authorities will adopt this recommendation also.

In his letter to the Coroner, Mr. Trotter incidentally referred to the mis-use of the word "electrocution," which, he said, was "a name given to a revolting form of capital punishment for condemned prisoners in America"; it should certainly not be used in the case of a man killed by accidental electric shock.

SERIOUS CABLE EXPLOSION IN MANCHESTER

EARLY on Monday morning, a serious explosion, due to a faulty cable joint, occurred just inside the Victoria Arcade, St. Mary's Gate, Manchester. Happily there was no loss of life, but the damage has been estimated at over £5,000. Several commercial premises in and near the Arcade have suffered considerable damage, as have also the gas and water mains.

According to the official statement issued by the Corporation Electricity Department, the fault occurred on the service wires laid into the Victoria Arcade at the point where they are jointed on to the distributing cables laid along St. Mary's Gate under the footpath, where there are five cables laid side by side in bitumen troughs. The defective jointing was the primary cause of the disaster. This was a very old service, laid in 1896, and the method of attaching the service cables to the distributing mains is not the one adopted to-day. The Department is rapidly changing over these old service cables, and jointing them up to the distributing mains in more up-to-date manner. The fusion of the cables melted the bitumen in the surrounding troughs, and the bitumen gas liberated would probably account for the force of the explosion. Four large gas service pipes, which were adjacent to the mains, were fused by the arcing which took place, and doubtless the gas contributed in no small degree to the extent of the damage done. The mains were tested last Sunday morning, and were then normal. At 1.15 a.m. on Monday morning a slight disturbance in the neighbourhood of Deansgate was indicated, but the "stand-by" men could find nothing wrong. At about two o'clock complaints were received from the Victoria Hotel, and several printing works in the city, and at 2.45 the explosion occurred.

Electric Power in Hemp Rope Works.—A correspondent writes asking whether any of our readers can furnish general information on hemp rope factories, stating, for example, if individual drive is largely adopted, ratio of maximum demand to h.p. installed, approximate load factor, number of units used per ton of rope produced, and approximate size of installation.

THE ELECTRICAL CONTRACTORS' ASSOCIATION

A NUMBER of members of the Electrical Contractors' Association (Incorporated), including some from the provinces as well as Londoners, met at the annual dinner of the Association on Monday. Among those whose conversation turned to business matters, the chief subjects of conversation were the municipal wiring clause in the Electric Lighting Acts (Amendment) Bill, and the special rebate which the Cable Makers' Association are allowing to members of the Electrical Contractors' Association. The Electric Lighting Acts (Amendment) Bill contaned a clause giving local authorities power to do house wiring themselves, but, largely by the efforts of the Contractors' Association, the clause in question was amended in such a way as to permit the municipality only to carry out such work through a contractor. An endeavour was first made by the municipal party to have the clause altered back again to its original form in the Commons on the second reading debate, but so as not to endanger the passing of the Bill, which contains other provisions of more value to the local authorities, the active opposition to the second reading is no longer being continued.

The rebate on cable purchases allowed by the Cable Makers' Association is under an agreement made about two and a half years ago, the result of which has caused considerable satisfaction among members of the Contractors' Association. Its terms are briefly that members receive their usual discounts as heretofore, but in addition the Contractors' Association, as a whole, receives a rebate of 7½ per cent. on the whole of its members' purchases for firms in the C.M.A. (whether of "Association" or "Non-Association" grade cables), if the aggregate amount of cable purchased exceeds £100,000 per annum. During the first year of the arrangement this total was not reached, and during the second year the purchases reached a total of £92,000, and, notwithstanding that the minimum arranged was not arrived at, the C.M.A. allowed a rebate of 5 per cent.

The guest of the evening at the Annual Dinner on Monday was Mr. W. M. MORDEY, President of the Institution of Electrical Engineers. In proposing the toast of "The Institution," Mr. G. Harland-Bowden hinted at there being a scheme under consideration by the Institution for the examination and certification of workmen. He also expressed the hope that the Institution's new building would eventually be a home for kindred associations.

Mr. Mordey, in his reply, said that the Institution of Electrical Engineers dealt rather with the principles than with the details of trade; it had to do with scientific, engineering, and professional questions, and, he said, had never had a trade or commercial side. Emanating from a movement made some years ago, a Committee which had been sitting for some time would complete during the course of the next session a code of rules for professional and business etiquette for the electrical industry generally, on somewhat similar lines to that of the Institution of Civil Engineers. Next time the Articles of Association were altered, the Institution would give itself more effective powers than at present for dealing with members who did not adhere to the standard set up. He next referred to the Institution's Committee on Wiring Rules (rules accepted by practically all the fire offices). The next edition of these rules would deal with cheaper methods of wiring, which he thought would open up a great field hitherto untouched. He himself was in favour of cheaper methods of wiring, for if our fears in the past had been justified, Mr. Mordey said, every house on the Continent would have been in flames long ago. The question of examination of applicants for admission to the Institution of Electrical Engineers was under consideration by the Council; he thought that the time had come to admit only those who could pass theoretical and practical examinations. Finally, Mr. Mordey referred to the controversy as to the state of the electrical trade in this country and Germany, and said that the amount of money spent on electrical contracts per head of population in Germany was less than half the corresponding figure spent per head in this country.

Mr. J. Snow Huddlestone (Siemens Bros. and Co.) proposed the toast of "The Electrical Contractors' Association." He said that since the inauguration of this Association the standard of work had been greatly improved. He also referred to the loss that the Association would sustain by Mr. E. L. Berry and Mr. Harrison, who are giving up their business in this country. Mr. Wallis, President of the Association, in the course of his reply, expressed gratitude to Lord Faber and Lord Avebury, who had done so much for them in the House of Lords in connection with the wiring clause which he had already referred to.

Mr. Leonard G. Tate, Secretary of the Association, proposed the toast of the Cable Makers' Association and kindred associations. He referred to the bounteous manner in which the Cable Makers' Association had acted up to the spirit of the agreement with the E.C.A. as to the rebate. Further, he said that the friction between the Incorporated Municipal Electrical Association and the Contractors' Association was apparent and not real, and that the word "meter" should never have been included in the Electric Lighting Acts (Amendment) Bill. He congratulated Mr. H. Berry and Mr. Hawes on the re-organisation of the National Electrical Manufacturers' Association.

Mr. L. Sawers replied on behalf of the Cable Makers' Association, Mr. C. McArthur Butler, Secretary of the I.M.E.A., on behalf of that Association, and Mr. Berry for the National Electrical Manufacturers' Association.

The last toast of the evening, the President and Honorary Officials, was proposed by Mr. E. L. Berry, who said that he feared he was leaving the Association at a period when it was conferring greater benefits upon its members than it had ever done in the past. It had, he said, even recently had the honour to be asked by the Board of Trade to draft a clause for an Act of Parliament. He referred appreciatively by name to all the men who had done good pioneer and committee work in connection with the Association, including Mr. W. Finlay, who is the president-elect for the coming session.

METROPOLITAN ASSOCIATION OF ELECTRIC TRAMWAYS MANAGERS

A MEETING of the members of this Association was held on the afternoon of Friday last, the 11th inst., at the Metropolitan Electric Tramways Offices, Manor House, Finsbury Park, N., those attending being Mr. Blain (West Ham), Chairman; Mr. Ullman (East Ham); Mr. Schofield (Leyton); Mr. Mittelhausen (Bexley Heath); Mr. Howard (Barking); Mr. Hammond (Metropolitan Electric); Mr. Mason (South Metropolitan); and Mr. Goodyer (Croydon), Hon. Secretary.

The members unable to attend were Sir Clifton Robinson (London United), Messrs. Bruce (L.C.C.), Balfour (Dartford), Coveney (Erith), Murray, and Spurr (Walthamstow).

The Hon. Secretary reported he had received various communications relating to Metropolitan Tramway matters since the last meeting, and, after having read the same, it was decided that several of them should be followed up. The visitors inspected the Company's offices, and, a special car having been placed at their disposal, they were conveyed to the Wood Green and Finchley depôts, accompanied by Mr. A. H. Pott (the Company's Chief Engineer) and Mr. A. L. Barber (Secretary). At both depôts Mr. Pott explained many matters of interest in connection with the working of the system. Twenty-five new bogie cars, Brush bodies, Mountain & Gibson bogie trucks, and G.E. 67 equipment, were in course of erection at the Finchley depôt, and Mr. Pott kindly pointed out several new features in connection with the same. The members were much pleased with the inside roofing design in the new cars.

The party subsequently returned to Finsbury Park, where they were very hospitably entertained on behalf of Mr. James Devonshire, the Managing Director, who was unavoidably prevented from being present. Mr. Blain, in moving a vote of thanks to Mr. Devonshire for his kindness in providing such an excellent repast, took the opportunity of heartily thanking Mr. Pott, Mr. Hammond, and Mr. Barber for the very satisfactory arrangements which they had been kind enough to make to enable the members to visit their extensive system, and stated that the members would look forward to having the opportunity later on of inspecting the Company's extensive repairing works, now in course of erection at Hendon.

Fatal Accident at the White City.—An inquest was held on Tuesday to inquire into the circumstances attending the death of J. Pridden, an electrician in the employ of L. Freeman, an electrical contractor, who died on Saturday from the effects of a shock received while wiring a motor employed to work the "Witching Waves" at the White City. It appears that Pridden had removed the cover of a terminal box to take out the fuses, but had not replaced the cover. While working he slipped, and came in contact with a live terminal. The jury returned a verdict of accidental death.

Long-Distance Telephony.—According to the *Daily Telegraph*, telephonic communication was established last week between Stockholm and Paris, and Sundsvall and Paris, *via* Copenhagen, a distance of 2,270 miles, with the aid of a new microphone, invented by two Swedish engineers. Efforts are now being made to obtain through communication between London and Copenhagen, *via* Paris.

Action *re* Rating of Motor.—In the Huddersfield County Court on Friday last Messrs. E. Brook, Ltd., electrical engineers, of Huddersfield, brought an action against Messrs. Newtons, Ltd., electrical engineers, of Taunton, to recover £40 2s., being the balance of account on the sale of four motors. The latter company admitted the claim, but counterclaimed for £34 16s. 6d. for defects in one of the motors, and paid the difference into court. The motor in question was a single-phase motor marked 6½ h.p., supplied at £23, and was installed at Kingston-on-Thames, coupled to a continuous-current machine for supplying a bioscope lantern. It was found that the motor would not do the work required, and Messrs. Newtons, Ltd., purchased a new motor, and incurred additional expense in changing the set. It was admitted that the purpose for which the motor was required was not stated when it was ordered, and Mr. E. Brook, of Messrs. E. Brook, Ltd., stated that if he had known that it was required for running a bioscope continuously, he would have supplied a different rotor. It also appears that the original motor was a 77-cycle machine, whereas the motor installed in its place was a 50-cycle motor. The judge gave a verdict for the plaintiffs, Messrs. E. Brook, Ltd., on both the claim and the counterclaim, with costs.

THE FOURTEENTH CONVENTION OF THE INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION

THE Incorporated Municipal Electrical Association will hold its fourteenth annual convention in Manchester from Monday to Friday next week, under the Presidency of Mr. S. L. Pearce, Chief Electrical Engineer to the Manchester Corporation. Mr. Pearce has been connected with the Association since 1903; he was elected to the Council in 1904, and to the Vice-Presidency in 1907. We give Mr. Pearce's latest portrait above, and the following biographical notes will doubtless be read with interest:—

COUNCILLOR A. SINCLAIR,
Reader of a Paper on
"Cheap Units."

MR. S. L. PEARCE
(*City Electrical Engineer, Manchester*),
President of the I.M.E.A.

MR. A. S. BLACKMAN,
Reader of a Paper on
Steam Turbines.

MR. E. S. LUNN,
Reader of a Paper on
Condensing Plant.

MR. E. E. HOADLEY,
Reader of a Paper on the
Metal Filament Lamp Question.

MR. E. M. HOLLINGSWORTH,
Reader of a Paper on
Cable Systems.

Mr. Standen Leonard Pearce is the son of the late Rev. Standen Pearce, of Crewkerne, Somerset. He was born in 1872 and educated at Bishop's Stortford College and Finsbury Technical College. In 1888 he was apprenticed to Messrs. J. G. Statter & Co. and after two years with them, completed his time with Messrs. Thos. Richardson & Sons, of Hartlepool. After over four years with this firm, the latter part of which he spent in the drawing-office, Mr. Pearce entered the service of the British India Steam Navigation Co., of London, and was for two years with them in charge of a "watch" on different vessels. From 1896 to 1899 Mr. Pearce was with the Metropolitan Electric Supply Co., and then joined the British Thomson-Houston Co. during the construction of the Central London Railway, afterwards acting for a short time as Superintendent Engineer at the Railway Co.'s power-house. In 1901 he was appointed Deputy Engineer to the Manchester Corporation Electricity Department, and in 1904, on the resignation of Mr. Metzger, he received the appointment of Engineer-in-Chief.

Mr. Pearce was Chairman of the Manchester Local Section of the Institution of Electrical Engineers in 1905-6, during which year he acted as Chairman of the Local Reception Committee in connection with the visit of the foreign kindred institutions. He was also a Member of Council of the Institution of Electrical Engineers in 1907-8. He has read the following Papers:

Digitized by Google

"Polyphase Sub-Station Equipment and Working" (I.M.E.A., Derby, 1904), "Manchester Tramways Power Supply" (Inst. Electr. Engrs., 1905), "Steam Turbines" (Manchester Section Inst. Civil Engrs., 1907), and "Steam Turbine Engineering" (Manchester Association of Engineers, 1908).

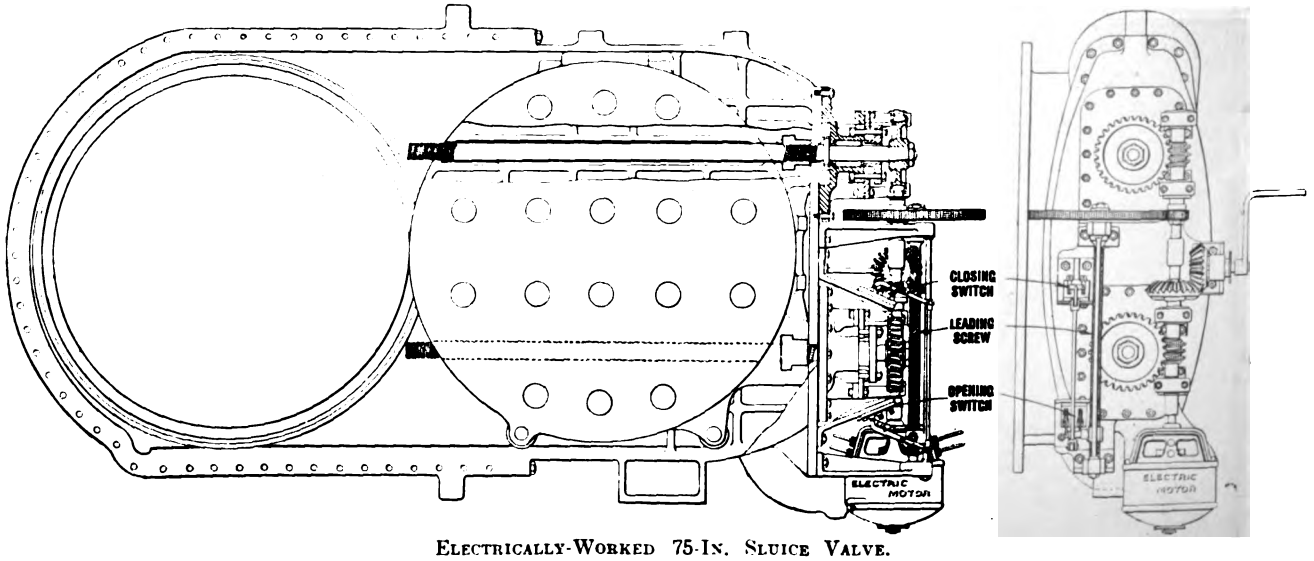
Mr. Pearce, in addition to being the City Electrical Engineer at Manchester, is also responsible for carrying out the extensions there. A 6,000-kw. turbo-alternator put down to his specification and under his supervision was recently started, and another of similar size is in hand, in addition to extensions of the boiler plant, and new arrangements for the water supply. Mr. Pearce identified himself energetically with the work of promoting and organising the electrical exhibition in Manchester last October, and acted as joint Consulting Electrical Engineer.

AUTHORS OF THE PAPERS

In accordance with our usual custom, we publish short biographies of the members who are down to read Papers. Their portraits appear on the previous page.

COUNCILLOR A. SINCLAIR, who will read a Paper on "Cheap Units" on Tuesday, was born in Aberdeen in 1861, and was educated privately at home and abroad. He took part as Assistant Electrician under Mr. Frank Jacob, of Messrs. Siemens Bros. & Co., in the manufacture and laying of the Mackay-Bennett cable, and afterwards was for some time with Messrs. Goolden & Trotter, Electrical Engineers, London. Since 1885 he has been Manager of the Electrolytic Works of Messrs. Vivian & Sons, Copper Smelters, Swansea. Mr. Sinclair, who is an Associate Member of the Institution of Civil Engineers, and a Member of the Institution of Electrical Engineers, has been for the past twelve years a Member of the Swansea Corporation, and is Chairman of the Electric Lighting & Tramways Committee.

MR. E. E. HOADLEY, Chief Electrical Engineer to the Maidstone Corporation, will read a Paper, "The Influence of Metal Filament Lamps on the Electrical Industry and on Street Lighting" on Tuesday. Mr. Hoadley was born at Rochester in 1874, and was educated at the Mathematical School, Rochester. After spending a year in the shops, he went to the Finsbury Technical College for two years, and was awarded the Sir David Salomons Scholarship by the Institution of Electrical Engineers in 1894. Since then he has held the following appointments: Junior Assistant, Chatham & District Electric Light Co., September, 1894, to September, 1895; Assistant, Eastbourne Electric Light Co., September, 1895, to January, 1896; Charge Engineer Islington Borough Council, January, 1896, to July, 1897; Chief Assistant, Worcester Corporation, July, 1897, to September 1898; Chief Electrical Engineer, Barking Urban District Council, September, 1898, to October, 1899; Chief Electrical Engineer at Worcester, October, 1899 to July, 1901; Chief Electrical Engineer, Maidstone, from then till present time.



MR. E. M. HOLLINGSWORTH, Chief Electrical Engineer, St. Helens, is the author of a Paper on "Modern Cable Systems," to be read on Wednesday. He was born in Garston in 1871, and served his apprenticeship in the shops and drawing offices of Messrs. Robinson, Cooks & Co. He received his technical education at the Municipal Technical Schools, Manchester. In 1894 he was appointed Lecturer on Engineering at the Gamble Institute, St. Helens. He was engaged by the St. Helens Corporation in 1896 as an Assistant Engineer in connection with their high-tension electricity scheme, for which Mr. Robert Hammond was the Consulting Engineer. In 1898 the Corporation decided to equip the tramways and to construct a new power station for continuous-current supply, and he was appointed Chief Assistant to Mr. J. S. Highfield, the Borough Electrical and Consulting Engineer. Upon that gentleman resigning in 1903, he received the appointment of Chief Engineer. Mr. Hollingsworth is a Member of the Institution of Mechanical Engineers, and an Associate Member of the Institution of Electrical Engineers.

MR. A. S. BLACKMAN, Chief Electrical Engineer to the Sunderland Corporation, reads a Paper on "Steam Turbines from the User's Point of View" on Thursday. Mr. Blackman, who was born in 1870, went to Messrs. Crompton & Co., at Chelmsford, in June, 1887, and left there to take up the post of Chief Assistant to the Hove Electric Lighting Co. Since then he has successively held the posts of City Electrical Engineer at Aberdeen, Borough Electrical Engineer and Manager at Poplar, City Electrical Engineer and Manager at Bradford, and Borough Electrical Engineer and Manager, Sunderland. At Poplar he was responsible for the complete designing, equipment, and setting to work of the electrical undertaking at a capital expenditure of £198,000.

MR. E. LUNN, who is Assistant Electrical Engineer to the Huddersfield Corporation, has been awarded the Travelling Studentship Prize for 1909 for his "Notes on Condensing and Water-Cooling Plants," which is the second Paper down for reading on Thursday. Mr. Lunn received his technical training at the Huddersfield Technical College. His practical experience commenced with three years' mechanical engineering in the shops and drawing offices connected with the Huddersfield Corporation Steam Tramways Department. He subsequently spent 2½ years on dynamo, motor, and switchboard construction work in the electrical department of Messrs. R. Holliday & Sons, Ltd., Huddersfield. In 1900 he was appointed Junior Assistant at the Huddersfield Corporation Electricity Works, where he now holds the position of Assistant Electrical Engineer. During the last two years he has had charge of extensions to plant to the extent of 6,500 kw.

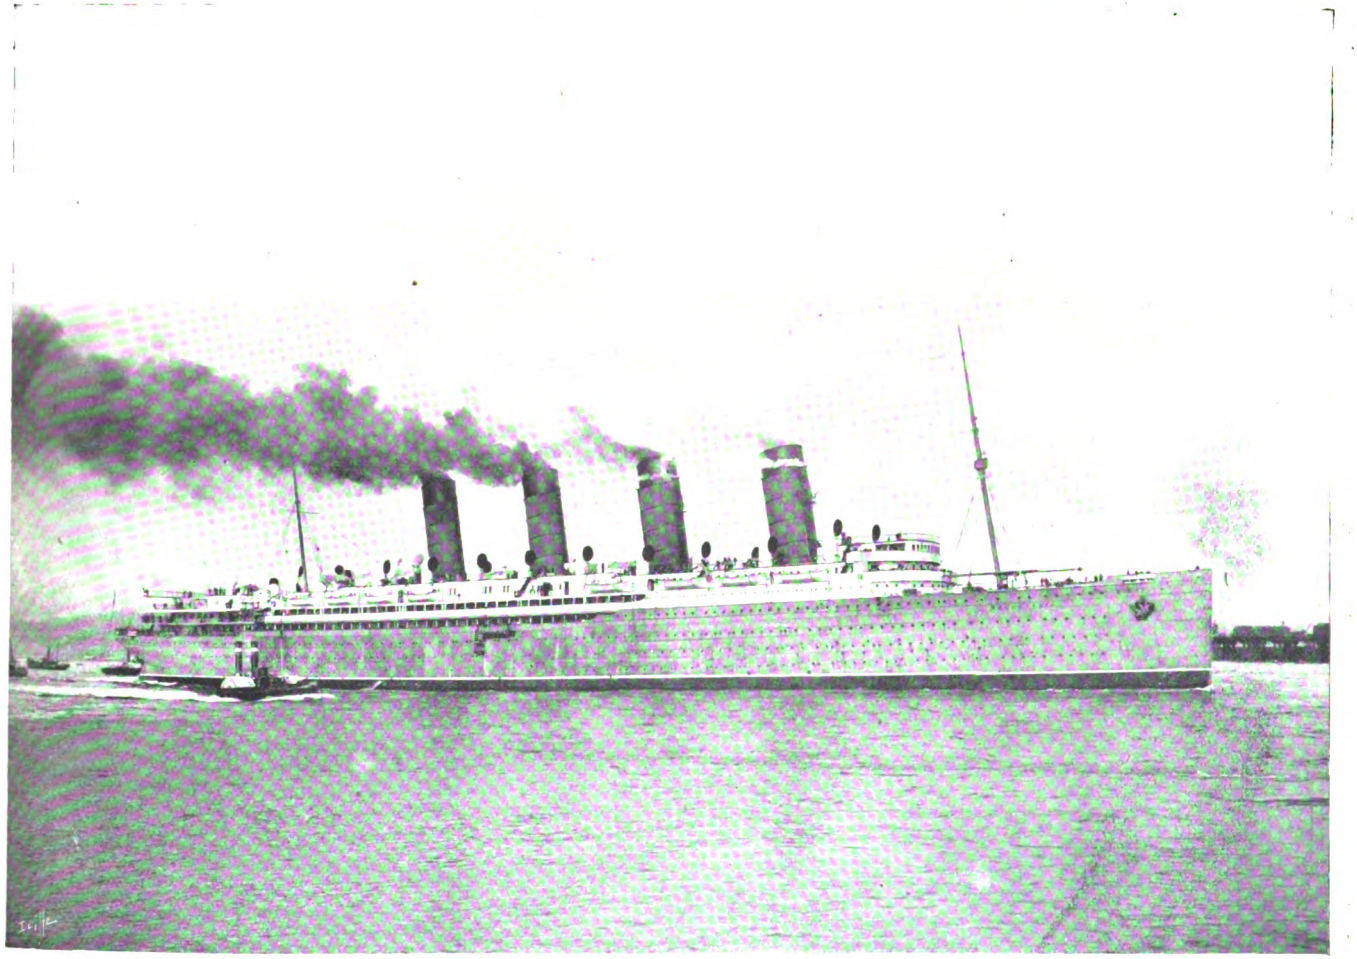
THE "MAURETANIA"

The visit that will probably be most looked forward to by the majority of members is the one that will be paid to the R.M.S. "Mauretania." Most of the members have easy opportunities of visiting electricity works, but the chance of inspecting one of the two largest Atlantic liners, and one with probably the most complete electrical equipment of any passenger steamer, is one that does not so frequently occur. Electricity is, in fact, used to so large an extent on this famous Cunarder that the total connections represent something over 2,000 kw.

ELECTRICALLY-WORKED 75-IN. SLUICE VALVE.

The generating plant consists of four continuous-current

Digitized by Google



110-volt Parsons turbo-generators each for about 410 kw. These are arranged in two pairs in separate watertight compartments, and in accordance with Admiralty requirements are below the water line. The switchgear is likewise in two sections, one in each engine room. Normally the two switchboards are connected together as one board, but they may be separated from either room so that each side of the ship can be operated as an independent installation. The main cables run under the water line to various power and lighting sub-boards at different parts of the ship, and where they pass through the boiler rooms, &c., they have a special heat-resisting covering. The auxiliary switchboards on either side of the ship are cross connected, so that in the event of one section failing the supply can be maintained from the other side. Wires from the auxiliary boards are mostly in wooden casings, and in all the rooms the frieze forms a covering to the casing. The wiring in the engine and boiler spaces is done with a special twin armoured cable afterwards painted.

In addition to the lighting and power cables, there are extensive bell, telephone, electric clock and other circuits which bring up the total wiring to something over 200 miles, including more than 100 tons of copper. There are over 6,300 lamps distributed over the ship, and in the design of the fittings ample provision has been made for the use of light reflected from the ceilings as well as from the lamps themselves. Perhaps the most important feature of the ship from the electrical point of view is the extensive use of electricity for power and heating, which amounts to a total of 2,133 h.p., independent of the supply for lighting.

For these purposes are installed 16 motors aggregating 800 h.p. for forced draught; 28 motors aggregating 276 h.p. for ventilating the machinery space; 18 motors aggregating 400 h.p. for auxiliary machinery in engine-room; 16 motors aggregating 52 h.p. for ventilating the ship; 53 motors aggregating 156 h.p. for the thermotanks supplying heated air; 4 motors aggregating 64 h.p. for refrigerating machinery; 2 motors aggregating 16 h.p. for two passenger elevators; 4 motors aggregating 108 h.p. for lifeboat winches; 8 motors aggregating 48 h.p. for electric jib cranes; 6 motors aggregating 78 h.p. for mails and baggage hoists; 6 motors aggregating 20 h.p. for hoists and stores; 2 motors aggregating 10 h.p. for printing machinery; 1 motor generator of 5 h.p. for wireless telegraphy; 20 h.p. for pantry and kitchen service machinery and hot plates; 80 h.p. for 106 electric radiators for special state rooms, bath rooms, and hospital.

Among these various applications of electrical power, attention may be particularly called to the electrical lifting gear for dismantling the main turbines and the electrical control of the large 75 inch exhaust steam sluice valves illustrated in the figure opposite.

Each of the latter is driven by a 12 h.p. motor and a travelling nut controlling switches in the motor circuit automatically cuts out the motors when the operation of opening or closing is complete. The fact that the valves can be opened or closed in a minute or two electrically, while it would take four men 2½ hours to close them is eloquent as regards the convenience of electrical drive for this class of work.

R.M.S. "MAURETANIA."

There are, of course, extensive bell and telephone installations, the latter of which is so arranged that on arrival in port the ship exchange can be connected to the Liverpool or New York exchange, so that passengers may be in communication with their homes or offices up till the hour of sailing or immediately on arrival. The navigating lamps are provided with signalling apparatus to indicate their failure electrically.

A point of additional interest to central station engineers is the fact that the blading of the main turbines of the "Mauretania" was partly made by Messrs. Willans & Robinson, at their works in Rugby, and partly by the Wallsend Slipway & Engineering Co., who were the builders of the turbines under licence from Messrs. Willans & Robinson.

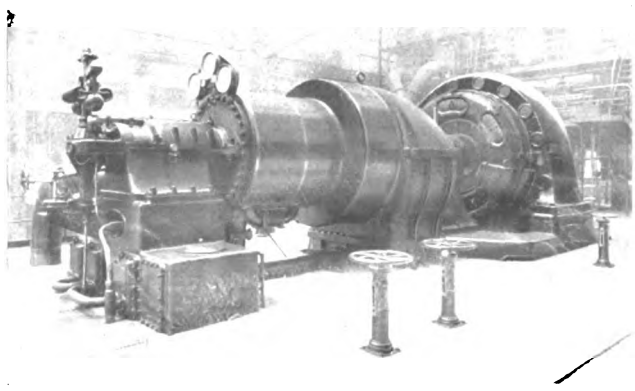
ELECTRICITY SUPPLY IN LIVERPOOL

Before proceeding to the "Mauretania" on Wednesday, visitors have been asked to inspect the Lister Drive stations of the Liverpool electricity supply department.

About twelve years ago, when the business of the Liverpool Electric Supply Co., and that of the Liverpool United Tramways and Omnibus Co. was acquired by the Corporation, the supply of electricity was furnished from four stations, in Highfield Street, Paradise Street, Oldham Place, and Lark Lane, aggregating 3,000 kw., and all equipped with Willans engines driving bipolar generators averaging 170 kw. capacity. To supplement these, the Corporation built, in 1899 and 1900, two new stations, at Pumpfields and Lister Drive. Each of these contained twelve 780 kw. Siemens 550-volt multipolar generators, running at 230 r.p.m., driven by Willans triple expansion engines; steam is supplied by Lancashire boilers. The plant in each station is arranged in four sections, any one of which can be used either on the traction or lighting service.

Subsequently to the establishment of these stations it became necessary to make provision for outlying districts which could not be economically dealt with by continuous current, and a second station equipped with three-phase plant generating at 6,000 volts was established adjoining the original Lister Drive station. Two out of the three sections into which this station will be divided are already complete, and the equipment of the third is in progress. The principal interest in this station lies in the fact that it is equipped entirely with turbine-driven machinery. The generating plant, when complete, will comprise four 2,000 kw. Westinghouse horizontal turbo-alternators and the three 2,500 kw. vertical Curtis turbo-alternators made by the British Thomson-Houston Co., shown in the accompanying illustration. B.-W. boilers are employed, supplying steam at 200 lbs. per sq. in. with 200° F. of superheat. The sub-station plant consists of motor generators of 200 kw. and 500 kw. capacity. The supply for lighting and power is given at 230 and 460 volts continuous current, the supply for motors over 6 h.p. being for the most part given at the higher voltage from the outers of the three-wire network.

The smaller stations of the Liverpool Corporation will not be visited, but it is interesting to note that a small amount of generating plant has also been put down to utilise steam from the Corporation refuse destructors at Lavrock Bank, Smithdown Road, Cobb's Quarry, Charter Street, and Garston, and these stations are also utilised as transforming and distributing points.



CURTIS TURBO-GENERATORS AT THE LISTER DRIVE STATION, LIVERPOOL.

During 1908, 13,823,157 units were sold by the Corporation for lighting and power, and 21,564,577 for traction. Street lighting is carried out by 193 arc lamps, and experiments are also being made with metal filament lamps for this purpose.

ELECTRICITY SUPPLY IN MANCHESTER

The Liverpool electricity undertaking is one of first magnitude, as will have been seen from the figures just quoted, but the electricity supply in Manchester is carried on on even a greater scale. The Manchester electricity supply department is the largest in the United Kingdom, and in 1908 nearly sixty-seven million units were sold.

The supply has been in the hands of the Corporation

6,000-KW. WILLANS SIEMENS TURBO-ALTERNATOR AT STUART STREET ELECTRICITY WORKS.

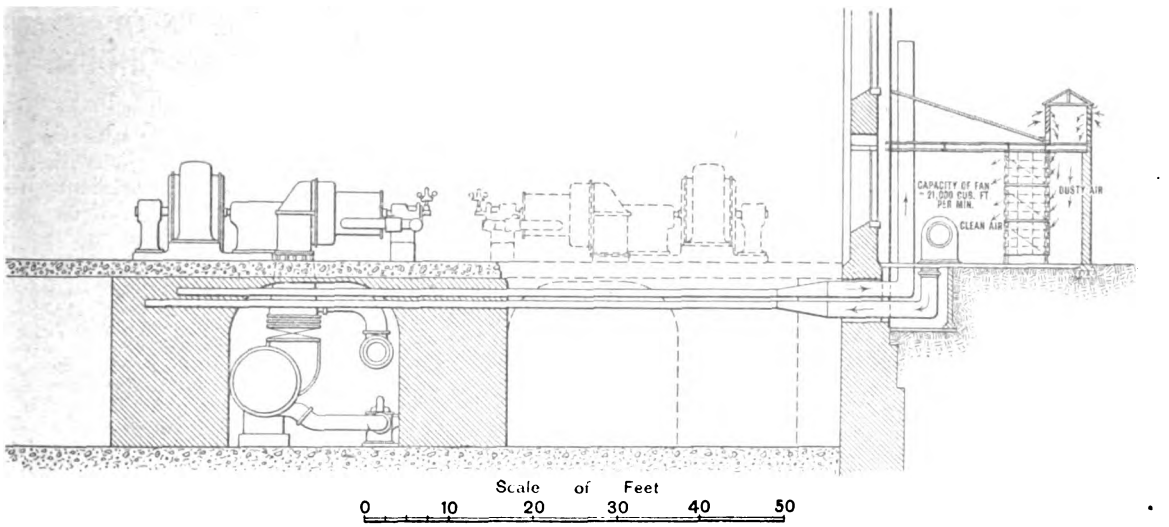
since 1889, and at the present time is carried on from three generating stations, opportunity to visit all of which will be given on Tuesday. Two of these, the Bloom Street station and the original Dickinson Street station, which it adjoins, are in the centre of the city, while the newest and largest station at Stuart Street is about $2\frac{3}{4}$ miles distant from them. In the generating plant of these stations are presented most interesting examples of the phases through which electrical engineering has passed during the last twenty years, including several descriptions of reciprocating sets and turbine-driven plant for both alternating and continuous current, and culminating in the fine new 6,000 kw. turbo-alternator, one of which is already running at Stuart Street. The last of the original 250 kw. sets belt driven by the aid of jockey pulleys, which were used at Dickinson Street in connection with the five wire lighting system put down by the late Dr. John Hopkinson, has, however, recently been removed. All three are combined traction, lighting, and power stations. Speaking generally, Dickinson Street and Bloom Street stations are for the supply of current for lighting and to the tramways within the City area, whilst Stuart Street supplies the current through the various sub-stations to the tramways and for lighting and power requirements in the outlying districts. It thus comes about that Dickinson Street and Bloom Street have low-pressure continuous current plant, and Stuart Street high-pressure three-phase alternating current machinery.

Taking first the Dickinson Street station, we find in the engine-room four reciprocating sets, two driven by 2,500-h.p. Musgrave engines, and two by Ferranti 1,200-h.p. engines, all of the vertical cross compound condensing type. The larger engines drive 1,500-kw. Siemens shunt wound generators, while Westinghouse 750-kw. compound wound traction machines are coupled to the smaller engines. The first turbine plant to be installed at Dickinson Street consisted of two 3,000 h.p. jet condensing Parsons turbines running at 1,040 r.p.m. each, driving a Parsons 900-kw. continuous-current turbo-generator. These were installed in 1902, and are still among the largest continuous-current turbo sets in this country. More recent continuous-current turbo-generators are exemplified in the two Parsons-Siemens 750-kw. sets. The principal features of these machines, which were described and illustrated in ELECTRICAL ENGINEERING, March 11th, page 227, are the "chimney" form of ventilation, and the use of compensating windings, as well as commutating poles, carbon brushes, and ventilated commutators with axial tunnels in the segments. These latter sets are used on the traction, as well as the lighting load. The boilers are partly of the Lancashire, and partly of the water-tube pattern, and mechanical stokers and economisers are used.

Digitized by Google

Part of the engine-room is devoted to converting machinery, which forms the connecting link with the Stuart Street station. This consists of a fine group of Bruce Peebles-La Cour motor converters aggregating 7,400 kw., the largest units being of 1,800 kw. capacity. In the summer months the Dickinson Street station is entirely shut down, and the supply to the central part of the town is taken from Stuart Street through these converters, and from Bloom Street.

Another point of interest in connection with the Dickinson Street station is the fact that a contract has recently been given for the installation at this station of what will be the largest storage battery in the country. The object of this battery is to utilise the surplus power from the traction generators in the daytime for charging the battery, and to discharge over the lighting peak, while on the traction bars it will also act to some extent as a buffer battery. The maximum discharge rate will be 15,000 amperes; it will give 11,200 amperes for half an hour, and 3,900 amperes for three hours. A special arrangement of boosters will be provided. Some further details will be found in ELECTRICAL ENGINEERING, May 6th, page 415.



The Bloom Street station, which is very compact, is principally used for traction supply in the central area of the city, but also for lighting and power. The generating plant consists of four 3,000-h.p. Musgrave vertical cross compound engines, each driving a Westinghouse 1,800-kw. 20-pole continuous-current generator, running at 75 r.p.m. The armature of each of these machines is 12 ft. in diameter, and weighs 50 tons.

The Stuart Street station supplies the greater part of the load, and contains larger units of generating plant. Current is here generated at 6,500 volts 50 cycles three-phase and transmitted to sub-stations. The site adjoins a canal, from which a certain amount of condensing water is drawn, but the remainder is taken from the town mains, or will be supplied from a bore-hole now under construction in Clayton Vale about 1,000 yds. from the station. Coal is obtained over a special siding 980 yds., built by the Corporation to connect with the Lancashire & Yorkshire Railway. The station has been constructed in two parts; the earlier portion consists of a boiler house, 200 ft. by 94 ft., in three bays, and an engine house, 114 ft. by 131 ft. wide, in which the generating plant is arranged at the sides, and the condensing plant and auxiliaries down the centre.

In this engine-room are six main 1,500-kw. three-phase E.C.C. alternators, driven by Yates & Thom vertical cross compound engines, running at 94 r.p.m. Motor-driven exciters are used, and excitation can also be taken from a battery. Three 200-kw. auxiliary continuous-current sets are also provided. The condensers are of the barometric type, and there are four large cooling towers. The switchgear in a gallery at one end of the engine-room is divided into two sections each for three of the generators, but is so arranged that the bus-bars of two parts can be so interconnected as to allow of all or any of the six generators to be connected to any or all of the H.T. lighting or traction feeders.

In the newer portion of the station, the boiler and engine houses adjoin, but are at right angles to those of the first portion. This boiler house is 139 ft. wide by 231 ft. in length, and running over its whole length is a coal bunker of 5,000 tons capacity. The first instalment of the generating plant comprised a pair of two 4,000 kw. E.C.C. alternators driven by vertical triple expansion four-cylinder engines of the Wallsend Slipway & Engineering Co., running at 75 r.p.m.

The engine room was originally designed for extensions consisting entirely of reciprocating engines, but Mr. S. L. Pearce, the present City Electrical Engineer, has abandoned this plan, and the next extension took the form of the 6,000 kw. Willans-Siemens set shown in the accompanying illustrations. A further set consisting of a similar Siemens alternator, driven by a Zoelly turbine, made by Messrs. James Howden & Co., of Glasgow, was ordered in May last, and is now nearly complete. By the use of turbines it will be possible to add to the original equipment to the extent of some 30,000 kw., in place of the 8,000 kw. of reciprocating plant for which there would have been room.

ARRANGEMENT OF VENTILATING PLANT FOR 6,000-KW. TURBO-ALTERNATORS AT STUART STREET, MANCHESTER.

The 6,000 kw. Willans-Siemens sets were described and illustrated in ELECTRICAL ENGINEERING, Vol. III., page 735, and some results of tests were given in Vol. IV., pages 275 and 311. One of the principal points of interest is the method of ventilation adopted. The alternator is entirely enclosed, and air is forced through it by an electrically driven blower of a capacity of 21,000 cubic feet of air per minute at a pressure of 3 inches of water. This blower is placed in a special house outside the engine room, and dust is removed from the air by an elaborate filter. The arrangement of the ventilating plant is shown in the accompanying figure. The set runs at 1,000 r.p.m., and the overall length does not exceed 36 ft. 3 ins. A steam consumption of 15·75 lbs. of steam per kw.-hour has been obtained on full load. The condensing plant, which is of the Contraflo type, with a cooling surface of 10,500 sq. ft., is situated immediately below the set. The new cooling towers which have been erected in connection with the turbine plant, were described and illustrated on page 532 of our last issue. A few particulars of the Howden-Zoelly-Siemens set were given in ELECTRICAL ENGINEERING, Vol. III., page 915.

In the same portion of the engine room are several motor-generator and motor-converter sets, which con-

Digitized by Google

stitute the Stuart Street sub-station. The switchgear by Messrs. Ferranti, Ltd., occupies three galleries on one side of the engine room. Provision is made for four generators and 24 feeders.

There are 19 more sub-stations in connection with the Stuart Street station, containing converting plant aggregating some 35,000 kw., not including a large number of sub-stations on the premises of important manufacturing firms to whom electric power is supplied by the Corporation. One of the sub-stations known as the "Polygon" sub-station will be open for inspection by members of the Convention, and here are also established the headquarters of the mains, street-lighting sub-station, testing and motor-hiring departments, and the electrical laboratory.

The distributing system comprises 135 miles of E.H.T. three-phase feeders, 37 miles of L.T. feeders for lighting and power, and 26 miles of traction feeders. Distributing mains are laid in 157 miles of streets, a five-wire continuous-current system is used for the central area, and a three-wire system for the outer area, with 400 volts across the outers in each case.

The total connections on the Manchester mains at March 31st, 1909, were equivalent to 1,505,210 8-c.p. (carbon) lamps. 66,924,864 units were sold in the last year, and the total maximum demand, including traction, was 31,335 kw. The average total cost per unit sold for the year ended March 31st, 1909, was 1·27d. (of which 0·53d. was accounted for by interest and sinking fund). Some idea of the magnitude of the undertaking will be gained from the statement that the total number of persons employed by the electricity department is 757.

THE SALFORD ELECTRICITY WORKS.

The present station in Frederick Road, Pendleton, to be visited on Friday afternoon, from which a supply of electricity is given to the Borough of Salford, was opened by the Corporation in 1901, and its initial equipment was very typical of the practice obtaining at that time when directly coupled reciprocating engines and continuous-current units of moderate size were almost universal in this country. Previous to the putting to work of this station, and before a tramway load had arisen, a single-phase alternating-current supply had been obtained from an older station at first with 100-volt house transformers, later with 200-volt street transformers and afterwards a 2 × 220-volt three-wire continuous-current supply was given through motor-generator sub-stations equipped with batteries. Thus the principal phases of central station practice have been well marked in Salford, including the latest steps exemplified in the 1,000 kilowatt Willans-Brown-Boveri continuous-current turbo-generator just installed.

This last-mentioned set brings the capacity of the station up to 7,400 kw., including the equipment of eight reciprocating sets, for which the station was originally designed.

The arrangement of the station is very simple, consisting mainly of a boiler-house containing a single row of boilers, and an engine-room, with a corresponding and parallel row of generating sets. A chimney, economiser, and pump-room are provided at each end, and the plant can be divided into two complete and independent systems in case of need. The coaling arrangements are also simple. Overhead bunkers extend along the whole length of the boiler-house, parallel to the adjoining canal, and a pair of electric jib cranes take the coal direct from barges into the bunkers.

The eight reciprocating sets consist of Browett-Lindley three-crank vertical tandem compound engines, driving Mather & Platt 800-kw. ten-pole compound wound combined traction and lighting continuous-current generators at 100 r.p.m. The main switchboards are of the plug board type, and the massive 2,000-ampere generator change-over switches are mounted on a frame in the middle of the room. The necessary balancer sets are in a separate room, which also contains some alternators from the old works, now driven by D.C. motors to supply outlying portions of the district with alternating current. There are also two 1,200 ampere-hour batteries, both of which are used in connection with the lighting and power supply.

Owing to difficulties which have occurred in connection with obtaining water from the canal for condensing purposes, a large scheme of cooling towers is now being erected, and is expected to be in operation within a few months' time. A bore-hole is also about to be sunk to obtain the necessary evaporation make up for the cooling plant. Mr. V. A. H. McCOWEN (Borough Electrical Engineer), informs us that the capacity of the station is now fully employed, and that the installation of a large battery to deal with the winter peak load is at present under consideration.

THE WORKS OF THE BRITISH WESTINGHOUSE CO.

On Thursday afternoon a visit will be paid to the works of the British Westinghouse Electric & Manufacturing Company at Trafford Park, which form the largest single manufacturing establishment in this country devoted to the construction of electrical plant. In addition to electrical machines and apparatus of every description for power, lighting, and traction, the manufactures include gas engines and steam turbines.

The total area of the site is 150 acres, of which 55 acres are actually enclosed within the buildings. Interest will centre principally in the large main machine and erecting shop, nearly 1,000 feet long by 450 feet wide, divided into five aisles, and provided with three spacious galleries, each in itself as large as many a complete engineering works. The largest machine tools, and these comprise some magnificent specimens of heavy lathes, many of American design, planers, &c., are mainly in the second and fourth aisles which have not galleries over them, and speaking generally it may be said that the western portion of the shop is devoted to the electrical erecting departments, while the steam turbine and gas-engine departments are on the opposite side.

The lighter electrical work is done in the galleries, where the switchboard, instrument, and other departments are situated, and where will be found one of the most interesting parts of the works devoted to armature and field coil winding and insulation, including special arrangements for working with enamel-covered wire, and adjoining which is a building containing extensive vacuum-drying ovens, &c. The machinery is almost entirely driven by three-phase, 440-volt, 25-cycle induction motors, but a few continuous-current motors are employed in some special cases such as where speed variation is required.

The head business offices, as well as the whole of the technical designing and drawing offices, are situated at the works, and are fitted up in a sumptuous manner, and with a completeness of organised detail rare in this country. It is as impossible to attempt an adequate description of so vast a works in a short space as it is to indicate the range of the electrical and engineering manufactures of the firm. In addition to viewing a works laid out on a scale that cannot be seen elsewhere in this country, the members of the Association will be able to examine examples of Westinghouse electrical plant of great variety, much of which represents years of research, carried on in the testing rooms at Trafford Park, and embodies ideas of originality emanating from the brains of English as well as American engineers.

ALTERNATIVE VISITS

The Lancashire Electric Power Company's Station at Radcliffe, near Manchester, which will be open to inspection by those members of the Association on Friday afternoon, who prefer to visit it in place of the Salford Electricity Works, was the first station in this country to supply a network of 10,000 volt overhead conductors for power distribution over a large area. Adjoining both a river and a railway, and situated within short distance of a colliery, it has exceptional facilities as regards coal and water. The station itself is of very compact design for its output, and the main generating sets consist of four vertical shaft Curtis turbo-generators of the four-stage type, made by the British Thomson-Houston Co. Each is rated at 1,500 kw. at 0·85 power factor, 11,000 volts, 50 cycles and runs at 1,000 r.p.m. The overload capacity is 50 per cent. for two hours. Hydraulic footstep bearings are used, in which the water pressure takes the weight of the shaft and rotor, and Mr. C. D. Taite, engineer and manager to the company, informs us that these are so free from friction that the sets will run for about an hour with steam and excitation shut off. The 11,000-volt switchgear is all of the remote control design, with the switches and bus-bars in brick cubicles, and interest attaches to the arrangements for leading out the E.H.T. feeders, all of which leave the station overhead, and are protected by multi-gap static dischargers. At present there are about seven miles of overhead lines, and thirty miles of underground E.H.T. cables. Some further details of the company's system will be found in an illustrated article in ELECTRICAL ENGINEERING, January 28th, page 87.

Digitized by Google

In addition to the visits arranged for Thursday and Friday afternoons, the works mentioned below will be available for alternative visits:—

The Works of the Lancashire Dynamo Co.—These works were erected in 1899 and now employ over 1,000 men. Electric driving is adopted throughout, and power is taken from the Trafford Power Supply Co. The works are divided into four main sections, the machine, winding, assembling, and testing departments respectively. The machine shop comprises two bays containing a large number of machine tools driven mostly by variable speed motors. The largest is an 18 ft. boring mill, and attention may be called to the electrical reversing arrangements of a side planer. All armature shafts are ground after turning, and pressed into the armature sleeves by a large hydraulic press. In the armature department, at right angles to the machine shop, are a series of hydraulic presses for the manufacture of micanite rings, troughs, &c., and three vacuum impregnating and drying tanks. In the next three bays, known as the assembling department, all the parts are put together to form a complete machine, and a well-thought-out stores system is in operation. Armature plate stamping, testing and packing are conducted in a separate building close to the main machine shop. In the testing special plant renders practically any voltage available, and insulating material can be tested up to 30,000 volts. Varnishing of armature plates is done in a separate building on account of fire risks. A feature of the firm's continuous-current machines is that the armatures in all sizes are built up on a cast-iron sleeve, so that the shafts can be easily changed. In the latest type of squirrel-cage induction motor, the end rings consist of several copper or brass stampings, like armature plates, with a quarter twist on each tooth to which the rotor bars are soldered. The automatic reversible boosters for the large new battery at the Dickinson Street station of the Manchester Corporation are being made here under Turnbull & McLeod's patents.

The Works of Messrs. Electromotors, Ltd.—The most striking feature of these works is the degree to which standardisation has been carried, and the care with which attention has been bestowed upon details of works organisation. The business was founded in 1899 to produce continuous-current motors in large quantities, and before manufacture was commenced some months were spent in the completion of designs and manufacture of jigs and special tools, so that machines could be turned out from the start on a large scale with the full advantages of thorough standardisation. Tracing the progress of the work, the motor bodies, &c., pass from the castings stores (in a separate building with the pattern shop) to the various machine tools without cessation, and, when machined, are stored in an allotted space within easy reach of the erecting bays. Machined light parts are collected daily from the machines and passed to the finished stores. The key-note to the whole establishment is the completeness of the tool-room, and the methods of storing the duplicate sets of gauges, jigs, and special tools needed for every individual step in the manufacture of machines. The erecting and testing bays are arranged so that the work makes, as far as possible, a continuous progress through them. Armature and magnet coils are made throughout in the girls' section, where the smaller armatures are also connected up, but the winding and soldering of armatures and the connecting up of the heavier sizes are carried out in the men's department in the adjoining room. Attention should be drawn to the ingenious system of electric bells, by which the desk of every leading hand is connected to the stores. The works is driven electrically, and lighted chiefly from its own power-house, but provision is also made for a stand-by and auxiliary supply from the Manchester Corporation Electricity Department.

The Hyde Road Car Shed of the Manchester Corporation Tramways will also be open for inspection on Thursday and Friday afternoons, by the courtesy of Mr. J. M. McElroy, General Manager of the Tramways Department.

The Manchester Municipal School of Technology will be open for inspection. This institution was opened in 1902 to provide facilities for the giving of technical instruction in mechanical, electrical, and sanitary engineering, applied chemistry, textile manufacture, architecture and the building trades, photography, and the printing crafts and many minor industries. The cost of the buildings and their equipment was mainly the gift of the legatees of Sir Joseph Whitworth. The main building is six stories in height, and covers a plot of land 6,362 square yards in area, and contains numerous lecture-rooms, in addition to extensive laboratories. The departments of textile and paper manufacture are housed in a separate adjoining building, 1,248 square yards in area. The number of individual students attending the day and evening classes, conducted under the supervision of Mr. J. H. Reynolds, the Principal, is about 5,000. The equipment of the mechanical engineering department includes several testing machines, an extensive hydraulic laboratory, steam, gas, and oil engines arranged for testing, and the laboratory for mechanics is founded on the methods of Professors Perry and Ewing. Electrical plant available for testing includes four 100-kw. steam dynamos of different types and 50-kw. turbo-generators in the central station, from which the school is supplied, and there are motors in various parts of the building aggregating 1,250 h.p. In the electrical engineering laboratory itself is a 40-kw. three-phase alternator, and examples of continuous and alternating-current plant of smaller size of great variety. There is also a 10-ton electric tramcar truck fitted with two 25-h.p. motors and controllers, and mounted on friction wheels for experimental work on problems relating to efficiency and acceleration. The testing-room adjoining the electrical engineering laboratories is fitted with Addenbrook's electrostatic instruments, and includes a well-equipped photometer-room. There are also advanced physical and special laboratories, and an electrochemical laboratory equipped with electro-deposition apparatus and electric furnaces.

The Polygon Substation and Testing Department of the Manchester Corporation, to which reference has already been made, may be visited, and

Messrs. Connolly Brothers' Works, Blackley, will, be open to inspection. In these works, which cover an area of two acres, the manufacture of indiarubber insulated wires and cables of all classes and of insulating tape is carried on.

The members of the Association are also invited to the generating stations of the Bolton, Bury, and Oldham Corporations.

At the **Bolton Corporation Electricity Works,** Mr. A. A. Day (Borough Electrical Engineer) can show the members two fine examples of slow-speed three-phase generating sets of 1,600-kw. capacity for 6,600 volts at 50 cycles; there is also older single-phase 460-volt 83-cycle plant, and as a traction supply at 550 has also to be given, the station contains a variety of motor-generators and rotary-converters for converting one type of supply to another. There is a considerable power-load in Bolton, partly supplied through rotary-converter substations. For the cotton-spinning machinery, however, three-phase induction motors are principally used. Attention should be drawn to the use of aluminium cables in the case of one of the substations.

The existing **Works of the Bury Corporation** does not present any great feature of novelty. It contains eight continuous-current Belliss-Siemens sets for combined traction and lighting load. An entirely new station is to be built, and a site has been already secured at Chamber Hall. Constructional work has not yet been started, but Mr. S. J. Watson (Engineer and Manager) will be pleased to welcome any visitors at the old station, and to take the opportunity of showing them over a few of the industrial undertakings which are wholly or in part driven from the D.C. mains.

The Electricity Works of the Oldham Corporation contains continuous-current plant for a combined lighting and traction load representing various stages of reciprocating-engine-driven generators, as well as turbo sets. Mr. S. Wilmott Newington, Borough Electrical Engineer, has lately prepared plans for considerable extensions.

LIST OF MEMBERS AND VISITORS ATTENDING THE CONVENTION.

The following gentlemen had notified their intention of attending the Convention up to yesterday (Wednesday):—

R. L. Acland (*Boro' Elec. Eng., Chesterfield*); S. T. Allen (*Boro' Elec. Eng., Carlisle*); W. H. Allen (*Boro' Elec. Eng., Loughborough*); Henry N. Allott; L. Andrews (*Key Engineering Co.*); J. Ashworth (*Vice-Ch'n, Heywood Elec. C'tee*); C. C. Atchison (*Boro' Elec. Eng., Rochdale*); Frank Ayton (*Boro' Elec. Eng., Ipswich*).

W. J. Bache (*Boro' Elec. Eng., Cheltenham*); E. A. Barker (*Boro' Elec. Eng., Barnsley*); A. S. Barnard (*Boro' Elec. Eng., Walsall*); C. O. Bastian (*Bastian Meter Co.*); J. Bastian; W. Bates; M. M. Bear (*Babcock & Wilcox*); J. Beecham (*Ch'n, St. Helens Elec. C'tee*); J. A. Bell (*Boro' Elec. Eng., Aberdeen*); C. Billington (*Billington & Newton*); G. Billington; W. Binns (*Tramways Eng., Reading*); R. Birkett (*Boro' Elec. Eng., Southend*); H. Collings Bishop (*Boro' Elec. Eng., Newport, Mon.*); A. S. Black (*Boro' Elec. Eng., Southport*); E. T. Blackler (*Ch'n, Torquay Elec. C'tee*); J. Blamires; A. V. Bland; T. W. Bloxam (*Boro' Elec. Eng., Belfast*); W. W. Blunt (*British Westinghouse Co.*); J. H. Bolam (*Chief Elec. Eng., Weymouth Elec. Works*); Horace Boot; J. Bowes; W. G. Boyd (*Ch'n, Londonderry Elec. C'tee*); Alderman Brady (*Ch'n, Barnsley Elec. C'tee*); A. Bremner (*Boro' Elec. Eng., Burslem*); S. E. Britton (*Boro' Elec. Eng., Chester*); L. Broekman (*Chloride Elec. Storage Co.*); N. M. Brown (*Ch'n, Greenock Elec. C'tee*); J. G. Bruce (*Chief Elec. Eng., Willesden Elec. Works*); J. K. Brydges (*Boro' Elec. Eng., Eastbourne*); J. Buchanan; Alderman A. A. Bumpus (*Ch'n, Loughborough Elec. C'tee*); A. H. Burbidge (*Burgh Elec. Eng., Kilmarnock*); H. R. Burnett (*Boro' Elec. Eng., Barrow-in-Furness*).

Eng., Harrogate*); J. Wilkinson (*Tramways Eng., Hull*); A. M. Willcox; T. P. Wilmshurst (*Boro' Elec. Eng., Derby*); Alderman D. L. Winter (*Ch'n, Rotherham Elec. C'tee*); A. P. Wood (*Lancashire Dynamo & Motor Co.*); C. J. Wood (*Chief Eng., Sale Elec. Works*); W. B. Woodhouse (*Yorkshire Elec. Power Co.*); L. W. Woodman (*Boro' Elec. Eng., Dover*); W. Wyld (*Boro' Elec. Eng., Birkenhead*).

W. Yates (*Ch'n, Swinton Elec. C'tee*); C. H. Yeaman (*Boro' Elec. Eng., Hanley*); F. A. Yerbury.

PREVIOUS CONVENTIONS.

The following is the list of towns in which previous Conventions have been held:—

Year.	*Town.*	*President.*
1896	London	Arthur Wright (Brighton).
1897	Manchester	C. H. Wordingham.
1898	London	A. H. Gibbings (Bradford).
1899	Bristol	H. Faraday Proctor.
1900	Huddersfield	A. B. Mountain.
1901	Glasgow	W. A. Chamen.
1902	London	J. H. Rider.
1903	Sunderland	J. F. C. Snell.
1904	Derby	T. P. Wilmshurst.
1905	Edinburgh	F. A. Newington.
1906	London and Kingston-on-Thames	J. E. Edgcome.
1907	Sheffield	S. E. Fedden.
1908	Nottingham	H. Talbot.

Digitized by Google

LOCAL NOTES

BANGOR: *Electric Lighting Accounts.*—The accounts for the year to March 31st show a revenue of £3,498, against £3,367 for the previous year. After meeting capital charges, however, there is a deficit of £490, against £333 for the previous year. The loss is largely accounted for by the increase in the cost of maintenance, the engines having been completely overhauled during the past twelve months.

BATH: *Corporation and Power Company.*—The Board of Trade has been asked for an Order stating that the powers of the Somerset and District Electric Power Co. in Bath shall cease, under the terms of the Company's Act. Already, owing to the Act not having been put into force, the powers of the company in Bristol have lapsed, and a certificate to this effect has been granted by the Board of Trade.

BOURNEMOUTH: *Tramway Electrical Energy.*—The report for the year to March 31st, of Mr. J. Bulfin, the Corporation Electrical Engineer, states that 1,932,273 units were generated and distributed, beng an increase of 23,335 units as compared with the previous year. The details are as follows:—Traction, 1,657,751; street lighting, 139,836; car-shed lighting, 64,729; car-shed power, 28,214; generating station lighting, 29,851; generating station power, 11,892. Notwithstanding the fact that the price of coal during the greater part of the year had been 18s. 3d. per ton, and that the outlay on repairs to buildings was considerably higher than in past years, the total working expenses had been kept as low as 1·014d. per unit, as against 1·061d. in the previous year, a saving of 0·047d. per unit generated. The revenue of £1,165 from the sale of current to the Lighting Committee still further reduced the working cost per unit for traction purposes to 0·93d. per unit. The engineer states that if the current generated at this station and used by the tramways during the past year had been obtained from the Bournemouth and Poole Electricity Supply Co., under their present amended conditions and prices, it would have cost the Corporation over £2,000 more.

EASTBOURNE: *Electricity Accounts.*—The revenue from the electricity undertaking for the year to March 31st was £25,109, the expenditure being £11,516. After meeting capital charges there is a net profit of £1,938. The units sold during the year amounted to 1,260,899, against 1,253,338 in the previous year. Power consumption continues to increase, and this has, to a certain extent, off-set the loss on lighting, due to the use of metal filament lamps. The number of units sold for power purposes has increased by 46 per cent., compared with 17 per cent. in the previous year, whereas the units sold for lighting supply increased by only 3 per cent., as compared with 9 per cent. in the previous year. The average price received for power supply was 2·26d. per unit, and for lighting supply 4·9d. per unit.

GILLINGHAM: *Diesel Engine Set.*—As announced under "Tenders Received," the Electric Light Committee recommend the acceptance of the Electric Construction Co.'s tender for a Diesel E.C.C. generating set. In reporting upon the tenders, Mr. A. D. Chalmers, the Council's Electrical Engineer, states that the Electric Construction Co. sent in the lowest tender for one of their generators combined with a four-cylinder Diesel engine by Messrs. Mirrlees, Bickerton & Day. As the engine portion of the plant is the largest and most important part, it would greatly assist matters when any question as to arrangement of piping and other details arose during erection if the Council could deal with the engine-makers as the main contractors for the engine, and recommends that the Electric Construction Co. be asked to arrange this as a condition of receiving the order. In the original specification sent out it was specified that the maximum variation in speed must not be more than 3 per cent. when the load is varied suddenly through the full range of the machine. The makers say they can comply with this if required, but the usual practice is to allow 5 per cent. Mr. Chalmers states that he has since been given to understand that if the governors are set to hold the machine to the specified variation, they will be much less sensitive for ordinary regulation. He therefore thinks it will be advisable to accept the makers' suggestions and allow 5 per cent. variation. Mr. Chalmers recommends the Diesel plant in preference to accepting the offer of the Kent Electric Power Co. of bulk supply at 0·875d. per unit, and gives the following reasons: There is a clear saving after meeting all capital charges of well over £400 per annum in favour of the Diesel plant. Although no cash allowance has been made in the estimates for it, a considerable saving will be made at times on the evening load by running the Diesel, taking the load in excess of the capacity of the steam set and boiler. With the bulk supply, when the load got beyond the capacity of one steam set and boiler in the evening it would be necessary to get another boiler and steam set away, which would at once reduce the all-round efficiency of the plant by a considerable amount. With the Diesel plant it has been proved conclusively that a unit can be produced for about 0·25d.; at this price it will undoubtedly pay to push to the very utmost the sale of current for cooking, heating, and power, but with bulk supply at 0·875 the margin of cost over selling price would be so small that it would not be worth making any special effort to obtain this class of load.

GRAYS: *Municipal Contracting.*—A resolution by the Electric Lighting Committee that the Electrical Engineer should not be allowed to carry out electric wiring and fitting on behalf of the Council has been adopted.

HUDDERSFIELD: *Extension of Supply.*—The Corporation have been asked to extend their supply to the South Crosland district. A Provisional Electric Lighting Order will have to be obtained, owing to South Crosland being beyond the Huddersfield boundaries. The Corporation have expressed their willingness to extend their mains into the district, and supply at prices 10 per cent. higher than those charged in Huddersfield.

ILFORD: *Tramway Energy.*—A recommendation by the Electricity, Lighting, and Tramways Committees that the price to be charged for energy for tramway purposes should be 1½d. per unit, has been adopted by the Corporation.

KEIGHLEY: *Tramway Accounts.*—For the nine months to March 31st, 1909, the receipts upon the Corporation tramways were £6,097, against £8,730 for the twelve months to June 30th, 1908. The number of passengers carried was 1,440,993, against 2,050,696. The actual traffic receipts show a decrease of £253 compared with the corresponding period of 1907-8, which is attributed to short time being worked in the district. The gross profits for the nine months amount to £1,708, but after meeting capital charges there is a deficit of £532. Complaint is made by the General Manager of the high charge for energy, viz., 1¾d. per unit. Other consumers in the town are charged a maximum of 2d. per unit, and a minimum of 1⅜d. per unit, less 5 per cent. discount, and, in view of the fact that the Tramways Committee are the largest users, they claim a lower rate.

LEEDS: *The Trackless Trolley System.*—The recommendation of the Tramways Sub-Committee to adopt the trackless trolley system for the Farnley district, of which particulars were given in our last issue, has been adopted by the City Council.

LINCOLN: *Tramway Accounts.*—There was a small deficiency of £98 upon the working of the G.B. surface contact tramways in Lincoln during the year to March 31st. The expenses per car-mile worked out at 5·60d., and these are compared with 75 other municipal tramways working on the overhead system for the year 1908, as this year's figures are not yet published. The average for the overhead systems was 6·37d. per car-mile, and for the Lorain system at Wolverhampton the costs for 1908 were 6·51d. per car-mile. The final payment of £1,000, the sum retained until the "G.B." Company had replaced the original type of conduit cable, was made to the company in December, 1908, on their completion of the work to the satisfaction of the Engineer.

LONDON: *London County Council.*—The Improvements Committee recommend that the cost of the subways now being built at the City end of the Victoria Embankment—namely, £30,000—should be charged to tramways account, owing to these subways being required in consequence of the construction of tramways over Blackfriars Bridge.

Poplar Tramways.—On understanding that the Poplar Council have approved, the Board of Trade has consented to the reconstruction of the Mile End Road tramways upon the conduit and overhead trolley systems.

St. Pancras: Motors on Hire.—The Electricity Committee have had under consideration the question of obtaining motors for the purpose of lending same to prospective consumers as a means of providing them with an opportunity of ascertaining the actual cost of electrically driving their machinery as compared with the cost of their present plant. A number of firms had been asked whether they would be prepared to lend motors to the department for this purpose, and Messrs. Bruce, Peebles & Co., Ltd., and Messrs. Cutting Bros., Ltd., have agreed to do so.

LOUGHBOROUGH: *Report on Electricity Works.*—In a report upon the general condition of the electricity undertaking, Mr. J. F. C. Snell says that although the plant on the whole appears to be working very satisfactorily, it is not of a type he would himself have recommended. He states that no reduction can be made in the number of the staff, but thinks that unnecessary outlay on mains was made in the first instance. The only remedy he can offer for this is to recommend that they should be loaded up as quickly as possible with new consumers. The commercial department is soundly managed, but one of the chief causes of the present unsatisfactory financial position is that the average rate per unit sold is too low. He recommends that the undertaking should be placed under the control of a separate electrical committee, instead of the Gas and Electricity Committee, and that all accounts should be kept by the Engineer instead of the Borough Accountant. In conclusion, Mr. Snell states he is unable to suggest any immediate remedy for the present position, and the only possible future remedy is a growth of output of higher-priced units, together with an economy of the severest kind in the costs of production, and the most

Digitized by Google

careful scrutiny of every addition to capital expenditure. The recommendations to form a separate committee, and that the accounts should be kept by the Engineer, have been rejected by the Corporation, but various proposals on matters of detail at the works have been adopted.

LYNN: *Electricity Accounts.*—The accounts of the Electricity department for the year to March 31st show an income of £6,607, and an expenditure of £6,164. The profit is about £100 less than that of the previous year.

MIDDLESEX: *Tramway Speeds.*—The London United Tramways Co. have applied to the Board of Trade for an increase of the maximum speeds on certain portions of the Company's lines. The Acton Council has agreed to an increase from 10 to 16 miles outside the business portion of Uxbridge Road, but the Ealing Council disapproves of any increase.

NEW MALDEN: *Electricity Supply.*—The Wimbledon Council have made an offer for supplying electricity in this district. The County of London Electric Supply Co. is at present in possession of a Provisional Order, but they have indicated their intention of not proceeding with it. In the proposed scheme by the Wimbledon Council, the Malden Council would be the distributing authority in the district.

PENRITH: *Electric Supply.*—The works which the Electric Supply Corporation have erected under agreement with the Council were opened last week. The plant at present consists of two 65-h.p. gas-driven sets, which have been supplied by Messrs. W. & P. Theermann & Co., of Manchester. Messrs. W. T. Henley's Telegraph Works Co., Ltd., supplied the cables. At present about 40 consumers have been connected up. The Consulting Engineer for the works is Mr. J. W. Speight, of St. Annes-on-Sea.

RHONDDA: *Tramway Extensions.*—The National Electric Construction Co., who work the tramways in this district, have replied to the Council with regard to certain suggested tramway extensions. The Tonyrefail route the Company does not regard as being sufficiently populated to support a tramway, although they think it would be well to obtain powers with the usual period of five years in which to carry out the works. The same applies to the Cwmpark extension. With reference to extensions to Mardy and Blaenrhondda, the Company are willing to proceed with the construction of these immediately the necessary Parliamentary powers are obtained.

SPAIN: *Madrid: Electrical Amalgamation.*—It is stated that an effort is being made to combine all the electricity companies of the City of Madrid under a central controlling board.

STOCKTON-ON-TEES: *Electricity Accounts.*—The income from the electricity undertaking for the year to March 31st was £8,273, an increase of £357 over the previous year. After meeting capital charges there is a good profit of £626.

TORQUAY: *Electricity Tariff.*—Upon the recommendation of the Electricity Committee the maximum demand system of charging is to be abandoned in favour of a graduated system of charging according to the amount of the consumption. For less than 25 units per quarter the charge will be 6d. per unit; above this and under 500 units, 4d. per unit; over 500 and under 1,000, 4d. per unit, and over 1,000 units, 3d. per unit. For arc lamps outside business premises the charge will be 2d. per unit. The effect of this new tariff will be a slight increase to private consumers.

WEYMOUTH: *Electricity Accounts.*—The gross receipts for the year to March 31st were £6,210, and the expenditure £2,838. After deducting capital charges there is a net profit of £101. The number of units sold was 388,051, an increase of 34,636 over the previous year. Connections now amount to the equivalent of 27,358 33-watt lamps, an increase of 3,465 during the year, whilst the number of consumers is now 369, an increase of 48 during the year. A new 300-kw. brush turbo-generating set has been installed during the year.

WOOD GREEN: *Electric Lighting.*—After strenuously opposing the North Metropolitan Electric Power Supply Co. for a number of years, and having been refused a loan by the Local Government Board to carry out a municipal scheme, the Urban District Council have now decided upon the advice of Mr. G. Spencer Hawes, their Consulting Engineer, to transfer their electric lighting order to the Power Co.

YARDLEY: *Electric Supply.*—In June, 1908, an agreement was entered into with the City of Birmingham Tramways Co. for a supply of electricity. Since then Mr. C. H. Gadsby, the Council's Consulting Electrical Engineer, has reported that the Board of Trade and the Local Government Board would not be at all likely to sanction the agreement, and recommend that it should be cancelled. An amendment to the resolution, however, was passed at the last meeting of the Council referring the matter to a later meeting of the Council, and in the meantime all members are to be supplied with copies of Mr. Gadsby's report.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

ASHTON-UNDER-LYNE.—An application is to be made to the Local Government Board for sanction to borrow £48,424 for extensions at the Electricity Works.

AUSTRALIA.—Tenders are invited by the Melbourne Corporation for a hand overhead travelling crane for the electric power-station. Particulars from Messrs. McIlwraith, McEacharn & Co., Billiter Square Buildings, E.C., and tenders to the Chairman, Electric Supply Committee, Town Hall, Melbourne, by August 4th.

BARNSLEY.—An application is to be made for sanction to borrow £3,000 for cables.

BEDFORD.—A 30-ft. by 8-ft. Lancashire boiler with steam pipe work and super-heater is required by the Corporation. Tenders by June 28th.

BRIGHTON.—A cable is to be laid to the Brighton Workhouse for driving the bakery and laundry machinery. It is expected that a revenue of £200 will be obtained from this supply. The contract is for a period of five years.

BRISTOL DOCKS.—The Docks Committee of the Corporation invite tenders for the supply, erection, and maintenance after 12 months of cables and fittings in connection with the electric lighting at Portishead Dock. Particulars from the Engineer, Cumberland Road, Bristol, and tenders by June 28th.

BURSLEM.—The Corporation invite tenders for (1) 600-kw. steam generator or turbo generator, (2) condensing plant, (3) water-tube boiler, (4) switchgear. Particulars from the Electrical Engineer, and tenders to the Clerk by June 28th.

BURTON-ON-TRENT.—Sanction to a loan of £4,000 for electrical purposes is to be applied for.

CLECKHEATON.—A Local Government Board inquiry has been held into an application by the Corporation for sanction to borrow £2,681 for extensions at the electricity works.

FELIXSTOWE.—Tenders are invited for a cooling tank, water softener, and ventilating plant. Particulars from Mr. R. P. Wilson, 66 Victoria Street, Westminster, and tenders to the Town Clerk by June 21st.

GILLINGHAM.—Tenders are invited by June 28th for the supply of coal to the municipal electricity works.

GRAVESEND.—The Electricity Committee require an automatic stoker. Particulars from the Electrical Engineer, and tenders to the Town Clerk by July 3rd.

IPSWICH.—The Electric Supply Committee invite tenders for rubber insulated wires and paper insulated lead-sheathed cables. Particulars from the Engineer, and tenders to the Town Clerk by June 20th.

LONDON: *Southwark.*—It is proposed to instal a battery with a capacity of 1,540-ampere hours.

Stepney.—The Finance Committee of the London County Council recommend the granting of a loan to the Stepney Council of £7,100 for building work in connection with the Blyth's Wharf Power Station.

NORTHAMPTON.—The Northampton Electric Light & Power Co. propose to instal a new boiler, economiser, overhead coal bunker, and a water-cooling tower. A 750-kw. generating set is also to be installed.

SALFORD.—The Corporation has approved a proposal by the Electricity Committee to spend about £12,000 upon the installation of a battery sub-station at the Frederick Road Electricity Works. Tenders for this have already been advertised for.

STEVENAGE.—The Urban District Council invite offers for working their electric lighting provisional order. Particulars from the Clerk.

STRETFORD.—A sub-committee of the Electricity Committee is inquiring into the question of the provision of a coal conveyor for the generating station.

WEST HAM.—A Local Government Board inquiry was held on Tuesday into an application by the Corporation for sanction to borrow £23,000 for the purpose of the electrical undertaking.

WOLVERHAMPTON.—Coal-conveying plant and mechanical stokers are to be installed at the Corporation electric power station.

Miscellaneous

BRITISH COLUMBIA.—It is stated that the British Columbia Electric Railway Co. intend to spend £500,000 upon extensions.

BUENOS AIRES.—The Compañia del Tranvia Puerto y Ciudad de Buenos Aires has been authorised to construct extensions of their lines in the city of Buenos Aires.

CHINA.—Tenders are being invited by the Chinese Telegraph Administration in Shanghai for the erection of wireless telegraph stations between the Altai Mountains and Ahsien.

DENMARK.—Large quantities of incandescent electric lamps, and carbons for arc lamps are required by the Danish State Railways. Particulars may be seen at the Commercial Intelligence Branch of the Board of Trade.

DUNMOW.—The Mid-Essex Water Co. are credited with the intention of installing electrical machinery at their Dunmow Works for lighting the pumping station, &c.

MEXICO.—The Mexico Tramways Co. has been authorised

Digitized by Google

to carry out various tramway extensions and modifications. Particulars can be seen at the Commercial Intelligence Branch of the Board of Trade.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

N.W.—Fire stations, Hendon. S. S. Grimley, Surveyor, Hendon, U.D.C.

W.—Building on site of Nos. 54-62 Oxford Street, and Nos. 53-58 Rathbone Place. Architects, H. P. Adams and C. Holden, 28 Woburn Place, W.C.

Branch, London, City, and Midland Bank, corner of New Bond Street. Builders, Waring and Gillow, Oxford Street, W.

New building corner of Duke Street. Architect, E. H. Dance, 185 Victoria Street, S.W. Builders, Cole & Co., Trafalgar Square, Chelsea.

PROVINCES.

DARLINGTON.—County School (£9,000). Architect, W. Rushworth, Shire Hall, Durham.

DUNDEE.—Extensions, East Workhouse (£3,000). Architect, T. Martin Cappon, 32 Bank Street, Dundee.

EXMOUTH.—Banking premises for Messrs. Lloyd, Ltd. Architects, Waller & Sons, College Green, Gloucester. Builder, R. F. Yeo & Sons, Torquay.

GATESHEAD.—Asylum (£10,000). Architect, G. T. Hine, 35 Parliament Street, S.W.

HEREFORD.—St. Nicholas Rectory (£1,216). Architects, Nicholson & Hartree, Offa Street, Hereford. Builder, R. Preece, Hereford.

LEEDS.—Tenders are invited for the wiring of the skating rink now in course of erection at Roundhay Road, Leeds.

NOTTINGHAM.—Extensions to workhouse (£6,000). Architect, A. Marshall, King Street, Nottingham.

POOLE.—School, High Street (£4,000). Architect, F. Newman, Council Offices, Poole.

ROTHERHAM.—School, South Grove (£11,000). Architect, D. B. Jenkinson, Rotherham.

STOKE-ON-TRENT.—Sunday school and Church room at St. Barnabas Church (£2,600). Architect, A. R. P. Piercy, Union Office, Stoke-on-Trent.

STRETFORD.—Telephone exchange, Trafford Park Road, for the National Telephone Co.

WEST HAM.—School (£24,000). Architect, c/o F. E. Hilleary, Secretary, West Ham Education Committee.

TENDERS RECEIVED AND ACCEPTED

BURY.—The tender of Messrs. J. Byrom, Ltd., has been accepted for the erection of the new electricity works at Chamber Hall.

GILLINGHAM.—The Electric Light Committee recommend that the tender of the Electric Construction Co. for a 140 kw. Diesel E.C.C. generating set at £2,420, be accepted. Further particulars are given under "Local Notes."

LONDON: *London County Council.*—Messrs. Hurst, Nelson & Co. are to supply 50 planks of 3-in. American oak for use in connection with the construction of 50 new car bodies at a cost of £120.

The tender of the General Electric Co. for the supply of a motor-generator and extensions to the existing switchboards at the London County Council School of Building, Brixton, has been accepted at £330.

Stepney.—The Council has accepted the following tenders for 8 feeder boxes, 11 distributing boxes, and 6 disconnecting boxes: J. Every, feeder boxes, £89 10s.; W. Cottis & Sons, distributing boxes, £125 10s.; W. Lucy & Co., Ltd., disconnecting boxes, £26 11s.

Stoke Newington.—The Council have accepted the tender of the British Thomson-Houston Co., Ltd., for the supply of electricity meters for two years.

Wandsworth.—The Council received the following tenders for the installation of electric light at the Putney Library: H. J. Whitehead, Fairfield Street, Wandsworth (accepted), £85; Weekes Bros., Hambalt Road, Clapham, £91; Tucker & Co., High Street, Putney, £97; J. H. Henderson, Orlando Road, Clapham, £98; Wright Bros. & Co., 27 Garlick Hill, E.C., £115 13; Dakin & Co., Upper Richmond Road, Putney, £121 17s.; W. G. Murrin, Trefoil Road, Wandsworth, £180.

Woolwich.—The Electricity Committee report that they have completed their inquiries as to the fair conditions of employment observed by the firms tendering for 2,100 yards, 3-core, 0·25 E.H.T. cable, and recommended that the tender of W. T. Henley's Telegraph Works Co., Ltd., at £384 10s., be accepted. This was agreed to. The other tenderers were: Western Electric Co., £383; Siemens Bros. & Co., Ltd., £391; W. T. Glover & Co., Ltd., £393; Johnson & Phillips, £396; Callender's Cable & Construction Co., Ltd., £396 10s.

STRETFORD.—The Council have accepted the tender of the British Insulated & Helsby Cables, Ltd., for cables: 0·3 sq. in., at 4s. 3d. per yard, and 0·15 sq. in., at 2s. 5d. per yard.

SUNDERLAND.—The tender of Messrs. British Insulated & Helsby Cables, Ltd., has been accepted for supplying, laying, and maintaining the cables necessary for the low-tension network in the centre of the Borough.

WORKSOP.—Orders have been placed with Messrs. Lucy & Co., of Oxford, for house service cut-outs; the Electric Ordnance and Accessories Co. for arc lamp globes, and the British Insulated and Helsby Cables, Ltd., for disconnecting joint boxes.

PARLIAMENTARY INTELLIGENCE

LONDON ELECTRIC RAILWAYS.—The Edgware-Hampstead, and Watford-Edgware Electric Railway Bills were ordered to be reported for third reading by the Unopposed Committee of the House of Commons on Thursday. The Bills provide for an extension of time for two years for the completion of the works already authorised. It was stated to the Committee that an arrangement had been made with the Underground Electric Railways Co. of London for the working of these two lines when constructed, but the capital for construction will not be found by the Underground Co. Many landowners along the routes have agreed to sell their land for the purposes of the undertaking, and to take payment in deferred shares.

OXFORD TRAMWAYS BILL.—This Bill, which has already passed the House of Lords, was passed by the Unopposed Committee of the House of Commons on Thursday. It authorises the National Electric Construction Co. to instal a combination of conduit and overhead trolley electric traction in Oxford, instead of the Dolter surface-contact system originally contracted for with the Oxford Corporation.

NORTH-EAST LONDON RAILWAY BILL.—This Bill was again before the Unopposed Committee of the House of Commons on Thursday, for the purpose of hearing financial evidence. The Bill was passed in 1905, when an obligation was put upon the promoters to find half the capital within twelve months. No capital has been raised, however, and extensions of time have been granted. Last year a twelve months' extension was granted by the Unopposed Committee of the House of Commons, when an intimation was given that the promoters must not come again for extensions. Despite this the capital has not been raised, but the promoters claimed the special indulgence of the Committee owing to the exceptional state of the money market during the past three or four years. When the Bill was considered by the Committee before Whitsun, the chairman said he must have an assurance that the capital would be obtained within the next year. On Thursday, Sir Thomas Truebridge, one of the directors of the company, and member of a firm of stockbrokers, stated that the conditions of the money market had improved enormously during the past six months; in fact, he had obtained more capital for industrial enterprises during the past two months than he had in the previous three or four years. He felt no doubt in his own mind that the money would now be obtained. The capital of the company is £3,000,000, of which the contractors will take £800,000 in shares, and the problem before the directors was to place 200,000 shares of £10 each. After considering the matter, the Committee passed the preamble of the Bill.

GREENOCK CORPORATION BILL.—This Bill was under the consideration of the Local Legislation Committee of the House of Commons last week. One clause deals with the supply for the Greenock & Port Glasgow Tramways Co., and in regard to this Mr. Kennedy, Parliamentary Agent, on behalf of the company, proposed to delete the clause under which the consent of the Gourock and Port Glasgow Councils was to be given before the Greenock Corporation could supply energy for the tramways of the company in these two districts. Mr. Sydney Morse, on behalf of the company, stated that this clause was in contravention of an agreement between the company and the Corporation, by which Greenock could supply electrical energy for the company's tramways without the consent of the outside authorities. In view of the peculiar circumstances, the Committee decided to leave the clause in the Bill in order to allow the parties to fight the matter in the next House.

LONDON COUNTY COUNCIL TRAMWAYS AND IMPROVEMENTS.—The Select Committee of the House of Commons, presided over by Sir George Doughty, has now completed consideration of this Bill. The Committee have sanctioned the construction of tramways down Farringdon Road to Charterhouse Street, and also across Battersea Bridge. Since the Whitsuntide recess a scheme for extending and reconstructing the tramways from Tooley Street and Woolwich has been passed. At present these lines are worked by horse traction, and consist of single lines with passing places, but it is proposed to reconstruct them for electric traction with double track. The Council has to carry out certain street widenings at Dockhead. The final proposal dealt with by the Bill was the reconstruction of the Highgate Hill cable tramways for electric traction on the overhead trolley system. The only opposition to this was on the part of the owner of some property who objected to being forced to sell this for the purpose of the necessary street widenings. The Committee, however, granted the Council the powers asked for, and the Bill was ordered to be returned for the third reading.

ELECTRIC LIGHTING ACTS (AMENDMENT) BILL.—Several notices of motion have been handed in, in opposition to the second reading of the Electric Lighting Acts (Amend-

Digitized by Google

ment) Bill, but these will no doubt be withdrawn, in view of the fact that the Incorporated Municipal Electrical Association now wishes the Bill to pass the second reading stage unopposed. The question as to the clause relating to wiring and fitting premises for electric supply by municipalities only through a contractor will then be dismissed in the Committee stage, as we have already announced.

LONDON ELECTRIC SUPPLY BILL.—When this Bill comes up for second reading in the House of Commons a motion will be put that it be referred to a Select Committee of five members, three to be selected by the House, and two by the Committee of Selection. The Bill constitutes the L.C.C. purchasing authority in respect of what are known as the "West End" companies, viz., St. James's & Pall Mall, Kensington & Knightsbridge, Central Electric & Notting Hill Electric Lighting, and Westminster Electric.

The Southport & Lytham Tramroad (Abandonment) Bill was read a second time in the House of Commons on Monday.

COMPANIES' MEETINGS AND REPORTS

ANGLO-PORTUGUESE TELEPHONE CO.—The report for 1908 states that the gross revenue was £42,048, of which operating, management, and general expenses absorbed £22,517, and royalties to the Portuguese Government £1,323, leaving a gross profit of £18,208. After providing for debenture interest, £2,433, sinking fund, £1,167, and income tax, £532, there remains a net profit of £17,820, including the balance of £3,745 brought forward. The directors now recommend a final dividend of 5 per cent. free of income-tax, making a total distribution of 8 per cent. for the year. It is also recommended that £5,000 be placed to reserve (increasing the same to £20,000), and that £4,820 be carried forward. At the meeting on Monday the report and accounts were adopted.

UNITED ELECTRIC TRAMWAYS OF MONTEVIDEO.—During the year to October 31st, 1908, the net receipts were £83,587, compared with £67,194 in the previous year. The number of passengers carried was 25,901,439, against 21,358,943. The conversion of the whole of the Company's lines to electric traction has now been completed, and a further extension to Colon of about three-and-a-half miles will shortly be opened. Owing to increasing traffic, additional rolling stock and generating plant has had to be ordered. The sum available for dividend is £61,432, and after meeting various expenses in connection with capital issues during the year, transferring £10,000 to renewals, the full dividend for the year on the 6 per cent. preference shares is recommended, and 5 per cent. on the ordinary shares, leaving £11,118 to be carried forward.

YORKSHIRE (WOOLLEN DISTRICT) ELECTRIC TRAMWAYS CO.—A dividend of 2 per cent. has been declared upon the ordinary shares. The sum of £1,500 has been placed to renewals fund, £1,000 to capital redemption fund, £500 to depreciation and reserve fund, and £608 carried forward.

BIRMINGHAM & MIDLAND TRAMWAYS.—The total revenue for the year 1908 amounted to £97,004, compared with £83,837 in the previous year. After providing for all expenditure, placing £1,500 to renewals, and bringing £83 from previous accounts, there is a sum available of £49,948. It is proposed to apply the sum of £5,550 to debenture redemption, and to pay a dividend of 2½ per cent. on the preferred shares, carrying forward £92. The Smethwick Power Station is to be sold to the Shropshire, Worcestershire, and Staffordshire Power Co.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f., port of arrival, quoted on Tuesday night, was £61 10s. to £62 (last week £62 10s. to £63).

ENGINEERING INSTRUMENTS, LTD.—Owing to the increasing demand for their mining switchgear and specialities, and the rapid growth of their business, Engineering Instruments, Ltd., are removing their works to Darlington, where they have fitted up extensive and modern shops. Their new address after the end of June will be Skerne Works, Darlington, where all communications should be sent.

FITTINGS, LTD.—We understand that this Company's stock of some thousands of pounds' worth of electric light fittings is being disposed of at a clearance sale, which is to last throughout the week. As the Company are moving from 112 Victoria Street, London, S.W., and will be engaged on a different class of business in future, no reasonable offer is being refused. Contractors should find it a good investment to acquire some of the fittings, which they should be able to place to good advantage amongst their clients.

NORTHERN LIGHT POWER & COAL CO.—This Company invites subscriptions for $1,750,000 5 per cent. first mortgage 20-year gold bonds at 90 per cent. The bonds constitute a first charge on the assets of the Company, which include the whole of the capital stock of the Dawson City Electric Light & Power Co., and the Yukon Telephone Syndicate, Ltd.

DISSOLUTION OF PARTNERSHIP.—The partnership between S. J. Suter and F. C. Wood, electrical engineers, 2 Lower James Street, Golden Square, W., has been dissolved.

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—A meeting of creditors of the Electrical Works and Development Co., Ltd., will be held at the offices of Messrs. Barnes, Dunn and Boughton, 52 Gracechurch Street, on June 28th, at 4.30 p.m.

The last day for receiving proofs in the bankruptcy of A. Roberts, trading as Roberts Bros., electrical engineers, 21 North Parade, Bradford, is July 3rd. The trustees are J. H. Haley, 29 Tyrrel Street, Bradford, and R. A. Vinter, King's Arcade, Bradford.

G.E.C., WITTON, *v.* ROBERTSON-OSRAM CRICKET MATCH.—On Saturday last, June 12th, the annual cricket match between the above clubs took place on the large and spacious ground of the former at Mill Hill Park, and ended in a draw. Scores, G.E.C., Witton, 75 for 8 wickets (innings declared); Robertson and Osram, 36 for 6 wickets. After the game both teams dined together in the dining hall at Brook Green Works, and a visit was then made to the "White City."

SMOKE PREVENTION.—A new smoke preventer is about to be placed on the market by the Furnace Appliances Co., of 9 Bedford Row, W.C., who state that very complete trials have been carried out during the past twelve months, which have shown that any class of fuel may be smokelessly and economically consumed with their apparatus. They have also acquired the business of the British Fuel Economiser & Smoke Preventer, together with their works, offices, &c., and will commence operations on July 1st.

APPOINTMENTS AND PERSONAL NOTES

Mr. O. H. Bishop, Sales Manager of the Edison & Swan United Electric Light Co., has resigned.

Mr. J. Bemrose, of the Worcester Electricity Works staff, has been appointed Chief Assistant Electrical Engineer at Tunbridge Wells, at a salary of £150. The Worcester Electricity Committee have appointed Mr. R. Smith, at present Mains Superintendent, to be Chief Assistant Engineer and Mains Superintendent, at a salary of £140, and Mr. E. Page, at present Mechanical Assistant, to be Station Superintendent at a salary of £120 per annum.

The salary of Mr. John Downie, Chief Clerk at the Ferryhill Electricity Works of the Aberdeen Corporation, has been increased from £150 to £165 per annum, with a further increase of £15 next year, and £20 in the following year.

A proposal that the salary of Mr. E. D. Long, the Electrical Engineer to the Grays Urban District Council, should be increased by £25 to £250 per annum has been defeated by one vote.

A station supervisor is required for H.M. Dockyard, Haulbowline, Co. Cork, to take charge of an electric generating plant. Full particulars in advertisement on another page.

NEW COMPANIES

PREMIER LIGHTING & ENGINEERING CO.—Registered on May 19th, with a capital of £3,000 in 2,999 ordinary shares of £1 each, and 15 deferred shares of 1s. 4d. each, to adopt an agreement between W. C. Sharpe, W. C. Sharpe, jun., and H. C. Robottom, and to carry on the business of engine builders in accordance with the patents referred to in the said agreement, engineers, machinists, manufacturers of and dealers in sanitary, heating, and lighting appliances, electricians, &c. The subscribers are:—H. C. Robottom, Denehurst, Glengall Road, Woodford Green, merchant; W. C. Sharpe, Eastfield, Louth, Lincs, engineer. Private company. The first directors are H. C. Robottom (chairman), and W. C. Sharpe (both permanent, subject to holding 500 ordinary or 5 deferred shares). H. C. Robottom has the right to appoint one other director. Registered office, 4 Lloyd's Avenue, Fenchurch Street, E.C.

F. A. WILKINSON & PARTNERS.—Registered on May 26th, with a capital of £500 in £1 shares, to acquire from F. A. Wilkinson the benefit of certain existing inventions for improvements in and relating to services for electric heating and wiring for houses and the like, &c. The subscribers are:—F. A. Wilkinson, Hotel Great Central, Marylebone Road, W., electrical engineer; R. C. Wilkinson, Ashbury Court, Beaworthy, North Devon, gentleman. Private company. The number of directors is not to be more than 4: F. A. Wilkinson is the first. Qualification, £250. Remuneration (except managing directors), £100 each per annum. Registered office: 58 Leighton Road, West Ealing.

Telegraph Traffic.—The French Cable Co. has had another breakdown on its West Indian system, the cable between Paramaribo and Cayenne failing on the 8th inst. The cable between Cayenne and Salinas is still interrupted. Cables to the Guianas are giving much trouble, and telegrams are being forwarded by steamer or sloop. The cable of the Indo-European Telegraph Co. between Lowestoft and Borkum was restored to working order on the 9th inst., but at that date the Lowestoft-Norderney route was still down. Lines between Bagdad and Bassorah were down on the 11th inst., and on the following day the Lowestoft-Norderney route of the Indo Co. was restored. Communication between Bagdad and Bassorah was again in working order on the same day. On the 14th inst. communication between Rome and Constantinople was interrupted, but this no doubt will soon be restored.

THE "FLAMGOLD" DOUBLE CARBON FLAME ARC LAMP

THE latest production of the arc-lamp department of the General Electric Co. is a line of gravity-feed flame arc lamps for both continuous- and alternating-current circuits. These lamps have been put on the market under the name of the "Flamgold" lamps, and there are two patterns in each case, namely, for one and two pairs of carbons respectively.

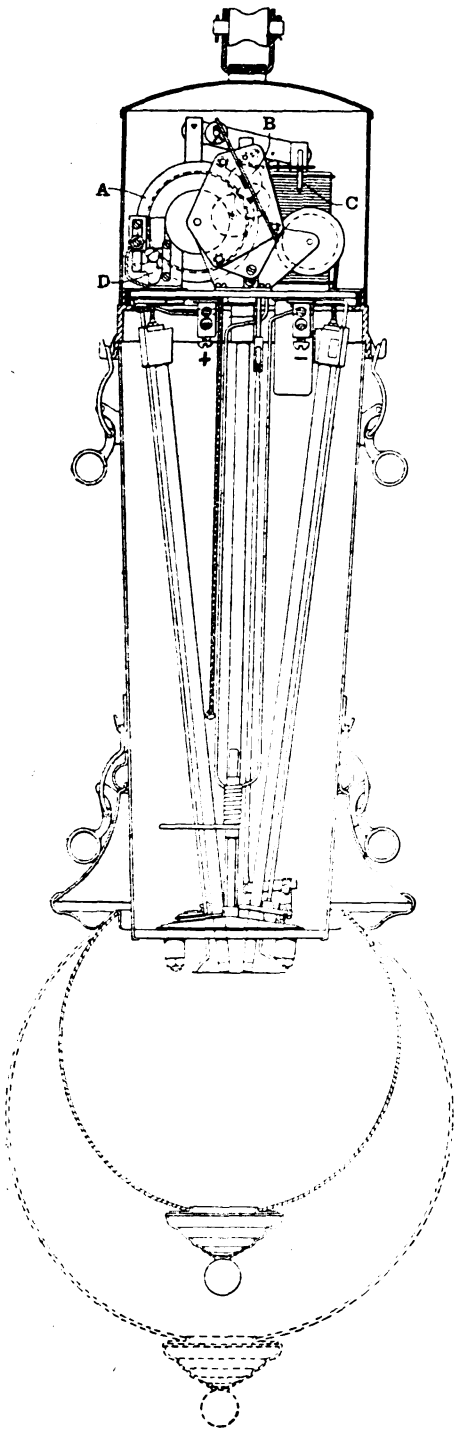

FIG. 1.—MECHANISM OF "FLAMGOLD" FLAME ARC LAMP.

The following is a description of the continuous-current lamp with two pairs of carbons, which is representative of the design of the other patterns as well, although the alternating-current lamps have some special features to render them noiseless and efficient; thus the solenoid cores are constructed of laminations of high-efficiency iron, and provision is made for the absorption of all vibration. The lamp is of the usual converging carbon pattern, and the carbons are fed down by their own weight and that of their holders, the clockwork mechanism for controlling their descent being released in the usual way by means of a swinging lever under the influence of the shunt and series coils. Although there are two pairs of carbons, there is only one clockwork mechanism, and no change-over device is needed, the carbons being fed down simultaneously. The burning time is thus doubled without either increasing the length of the lamp or adding complicated mechanism.

The action is as follows: the two pairs of carbons are connected in parallel, and on switching on the lamp the arc is struck between one pair. The series solenoid then immediately draws out the arc to its proper length by means of the rod attached to a sliding plate or collar surrounding the negative carbons and carried on rollers. As the carbons are consumed, the clockwork is released by a detent on the regulating lever, and the carbons are allowed to feed. This feeding goes on for from 15 to 20 minutes, during which time the pair of carbons not in use gradually approach one another and finally touch, short-circuiting the arc across the other pair. The arc is, however, instantaneously drawn out between the second pair of carbons and extinguished on the other pair by the action of the series solenoid which separates the carbons in consequence of the increase of current. Feeding of both pair of carbons then takes place until the first pair again come in contact and short-circuit the arc across the second pair. The change over from one pair of carbons to the other is repeated every 15 or 20 minutes, but it is hardly noticeable, as the arc is burning across both pairs of carbons at the instant of changing over, and is never extinguished entirely.

A general view of the mechanism of the lamp is given in Fig. 1. The carbons are suspended from an insulated drum *A* by means of woven copper cords, the usual beaded flexible connections being dispensed with. The drum itself is divided into two halves in its own plane by a vulcanite disc, and its axle is keyed into the hollow axle of the largest wheel of the clockwork train. This latter construction permits the ready removal of the clockwork for cleaning without disturbing any of the other mechanism. The copper cord supporting the positive pair of carbons is passed twice round and fixed to one half of the drum, while the cord for the negative carbons is fixed to the other half. Two revolutions of the drum corresponds to the full feed of the carbons, and to obviate the necessity for rubbing contacts, a coiled copper strip in each half of the drum is fixed at one extremity to the drum and at the other to a fixed terminal, and thus gives an unbroken circuit from lamp terminals to carbon holders. The clockwork train ends in a brake wheel *B*, to which is attached a fan blade, and is released when the detent *C* on the regulating lever lifts the brake from the wheel, under the influence of the shunt coil.

An interesting feature of the lamp is the economiser, the design of which, together with the magnetic "blow-out" or control arrangement appears to have received most careful attention. A rough sketch of this portion of the lamp is given in Fig. 2, which, though not to scale, gives a good idea of the arrangement. The economiser itself is a bell-shaped brass casting, *A*, divided into two halves by a partition as shown in the figure. Insulating bushes are provided where the positive carbons pass through the roof, and mica insulation is provided between the economiser and the positive guide plate *C* and the frame plate *B* respectively. The sliding plate or collar *L* runs on little metal wheels on the top of the economiser to ensure smooth regulation and evenness of burning.

Digitized by Google

The arrangement of the "blow-out" magnets is also shown in Fig. 2. It will be noticed that the iron rods on which the series turns are wound are both extended to below the rim of the economiser and flattened so as to give a field at right angles to and below the arc. This fields prevents the arc from travelling up the carbons, and also keeps it at the cores. Readers interested in this subject should refer to an abstract of an article by Dr. Teichmüller, and the ensuing correspondence, which appeared in ELECTRICAL ENGINEERING of January 7th, 1909, and the two following issues. It may be mentioned that in the lamp under consideration there are 12 turns on each iron rod; the current is nine amperes. The flattened extensions to the arc controlling magnets are not shown in Fig. 1, as they are only

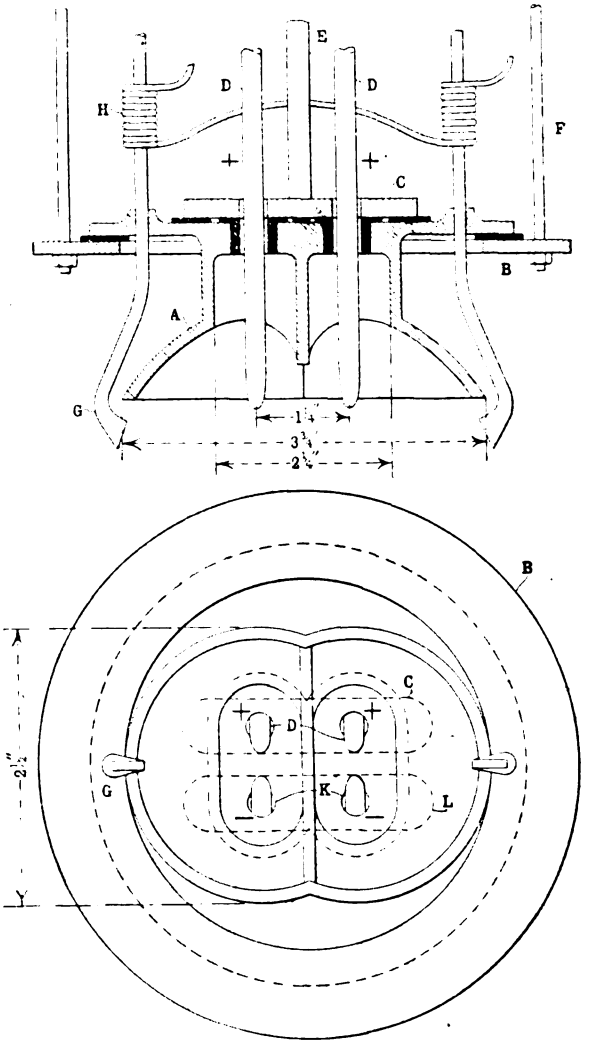

FIG. 2.—SKETCHES OF ECONOMISER, SHOWING THE CONTROLLING MAGNETS.

used in the case of the double carbon lamps; the drawing of Fig. 1 refers to a lamp with either one or two pairs of carbons, the mechanism being exactly the same in each case. As indicated in the drawing there are two sizes of globes, a 10-in. globe or a 13-in. globe.

To extinguish the arc when the carbons are fed down to their lowest position, and to avoid any possibility of the full pressure of the circuit being impressed on a single shunt winding when two or more lamps are run in series, a switch (*D* in Fig. 1) is provided to break the shunt circuit when the carbons are completely fed down. This switch is operated by a stop extending out from one side of the drum which, on the second revolution of the latter, *i.e.*, when the carbons are fully consumed, operates the switch. On rewinding the drum to trim the lamp, this switch is automatically closed. A woven copper cord is provided to rewind the drum, as it was found that an ordinary cord was destroyed by the fumes from the arc. To bring up the resistance of the shunt to the required amount, a length of resistance wire is wound over presspahn on the outside of the coil.

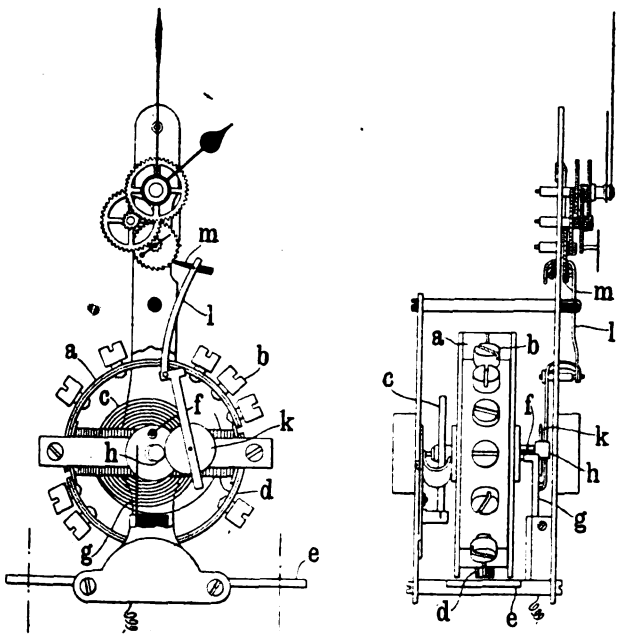
Among the special features of the lamp which, as yet, have not been mentioned, are the knife-edge bearing for the regulating lever, the threaded air dash-pot, and the carbon holders which are constructed to ensure automatic alignment of the carbons and, consequently, quick trimming. The two carbon holders of like size are in one piece, and are guided by a single strip, *E*, as shown in Fig. 2. Both outdoor and indoor lamps have non-corrosive zinc cases fitted with rapid-fixing snap-catches and decorated with spun copper flanges. The globes are permanently wired to a copper corona, which can be removed from the lamp case for cleaning. "Nubia" flame carbons, 18 in. long, and either coppered or metal cored, are used for these lamps. The positive carbon is 9 mm. in diameter, and has an impregnated (flame) core. The negative carbon has a plain core, and is 8 mm. in diameter.

The standard continuous-current double carbon lamp takes 9 amperes with 40-43 volts at the terminals, and burns from 18 to 20 hours on one trimming. The weight, including globe, is 29 lbs., and the length overall 38 in. The alternating-current lamp takes 10 amperes, and burns from 16 to 18 hours on one trimming. Owing partly to the use of choking coils instead of line resistance, and partly to the distortion of the current wave by the arc itself, the alternating-current lamp consumes only from 320 to 350 watts, including the loss in the choker.

In conclusion, we should like to acknowledge our indebtedness to Mr. A. Angold, Mr. D. McLagan, and Mr. W. Krause for their kind assistance in the preparation of this article.

Frankfurt-Wiesbaden High-Speed Railway.—The plans for this railway are now complete, and the Felten & Guilleaume-Lahmeyerwerke Akt.-Ges., who are the promoters of the scheme, have come to satisfactory arrangements with the local authorities concerned. The Prussian railway authorities, however, are not inclined to grant the concession for the long period asked for by the promoters, but wish to take over the railway much sooner. The total length of the railway will be about 20 miles. The trains will run in the streets at tramcar speeds, but outside the towns will attain a speed of over 60 miles per hour. Slow trains stopping at intermediate stations, as well as express through trains, will be run. The latter will take only 25 minutes to make the complete journey, whereas the fastest steam trains take 44 minutes.

Linking Up of the London Electricity Supply Works.—In our issue for June 3rd, p. 514, we gave the list of names of Borough Council representatives upon the Committee which is to draw up rules of procedure in connection with the proposal to link up the London Electricity Undertakings. We are now able to give the companies' representatives, which thus completes the Committee:—Mr. R. Stewart Bain, London Electric Supply Corporation, Ltd.; Mr. H. R. Beeton, of the Brompton & Kensington Electricity Supply Co., Ltd., and the Chelsea Electricity Supply Co, Ltd.; Mr. J. B. Braithwaite, City of London Electric Lighting Co., Ltd.; Mr. Harrison Cripps, Metropolitan Electric Supply Co., Ltd.; Mr. W. F. Fladgate, Charing Cross, West End & City Electricity Supply Co., Ltd.; Mr. R. Percy Sellon, County of London Electric Supply Co., Ltd.



Electrically Operated Refrigerating Plant.—The report of the British Consul at Philadelphia contains a description of a refrigerating plant for meat storage, comprising two refrigerating machines, each driven by a 50-h.p. motor, one three-throw brine pump driven by a 5-h.p. motor, and a condenser pump coupled to a 4-h.p. motor. The brine tank holds 5,000 gallons, and the brine is cooled to a temperature of from 5° to 8° F., by means of the expansion coils in connection with the refrigerating machines. There is a lift worked by a 6-h.p. motor. It is said that the cooling of the storage chambers is effected much more economically by the circulation of the brine than by the former method of storing the meat in ice-cooled rooms. The use of freezing-rooms is also rendered possible with the new equipment. Some notes on the supply to refrigerating plants as a means of improving the load factor of generating stations were published in ELECTRICAL ENGINEERING of January 7th, 1909, page 13.

NEW ELECTRIC CLOCK

A NEW self-contained electric clock will shortly be put on the market by the Eureka Clock Co., Ltd., of 361 City Road, London, E.C. The clock, which is the invention of Mr. S. Kutnow, has no pendulum, and is designed to go in any position. It appears to be strong and simple in construction, is noiseless in operation, and, we are informed, will compare favourably in price with spring operated clocks of equal quality. The clock is worked by one dry cell.

In the accompanying figures, which illustrate the working of the clock, *a* is a 12 oz. balance-wheel, compensated for temperature by being constructed of a brass and a steel rim sweated together in the usual manner; the screws *b* are for adjusting the balance. The wheel is supported at both ends in ball bearings, and to minimise the friction if the clock is not set level, crystal plates are provided for the pointed ends of the balance-wheel shaft to bear against. The oscillations of the wheel are controlled by a large isochronic hairspring *c*, which ensures that the time of swing is independent of the amplitude. The wheel traverses an arc of 360° at each half period. Fixed diametrically across the wheel is a core *d* of soft Swedish iron wound with enamelled covered wire. This is shown horizontal in the left-hand figure, and vertical in the right-hand figure. Two strips of soft iron, one on either side of the core, form a return path for the magnetic flux; the magnetic circuit is

FRONT AND SIDE VIEWS OF "EUREKA" ELECTRIC CLOCK.

closed at one end and open at the other. The open end passes over the grooved soft iron plate *e* once in every half period, and once in every period the core on the wheel is magnetised and an impulse given to the wheel. The tension of the hairspring is regulated so that the balance wheel makes forty swings or twenty complete oscillations per minute.

Contact is made by means of the pin *f*, which wipes against a platinum strip at the end of the spring *g* at each swing. The pin is of ivory, with a small segment of metal on one side only, and as it wipes the spring alternately on opposite sides, contact is made every other swing only—*i.e.*, every three seconds. The time during which contact is made is only about 1/80th of a second, and as the resistance of the coil is 36 ohms, and the pressure that of one dry cell, it will be seen that very little energy is required to keep the clock going. There is sufficient energy stored up in the oscillating system to keep the clock going for 30 or 40 seconds without any impulse. Every time the cam *h* passes the wheel *k* it lifts it, and by means of the lever *l* and the pawl *m* moves on the second-hand wheel one tooth. The only other wheels are the minute- and hour-hand wheels, and there is no escapement.

It will be noticed that the impulse is given in the centre of the swing, this being the most favourable moment. The mechanism can be adapted to any size clock from a small carriage clock to a large dial clock. A large number of clocks are in course of manufacture at the factory in City Road, and will be put on the market in a few weeks' time. It may be mentioned that Mr. Kutnow recently had the honour of showing one of these clocks to his Majesty the King.

MUNICIPAL FINANCIAL ORGANISATION AND ADMINISTRATION

THE Institute of Municipal Treasurers and Accountants (Incorporated), has been making itself unpopular in municipal circles by taking up the self-imposed task of preparing a "model" set of regulations "for securing uniform and efficient financial control and organisation of municipal accounts." This step was decided upon at the annual meeting of the Institute, held at Edinburgh, in June, 1908, and a sub-committee was appointed who drafted a complete and very drastic set of regulations, which were briefly to the following effect:—

All municipalities should appoint a Finance Committee for regulating and controlling their finance, and no order for payment of any sum should be made except upon the recommendation of this Finance Committee.

A chief financial officer should be appointed, who would assist the various heads of the departments in the preparation of their estimates, but these estimates must have the approval of the Finance Committee. No estimates should be submitted to a Council other than through the Finance Committee, except in cases of emergency.

Separate annual estimates of capital and revenue account, would, under the proposed regulations, have to be submitted to the Finance Committee by each of the Committees in a certain stipulated month of the year, in such form as the Finance Committee might from time to time prescribe. The Finance Committee would prescribe the amount to be borrowed in respect of any department during any one year.

The general effect of the proposed regulations would be to transfer from individual committees to the proposed Finance Committee the direct control of all expenditure; in fact, the committees of all Corporations would, if the proposed draft regulations were to receive the sanction of the Local Government Board, have to discuss their financial matters with the proposed Finance Committee, who, in turn, would place their proposals before the Corporation instead of the shorter process at present adopted of each committee dealing direct with the Corporation.

To these proposals the Incorporated Municipal Electrical Association, in conjunction with the Muncipal Tramways Association, has offered the most strenuous opposition. It was, we believe, originally intended that the draft set of regulations should have been submitted to the annual meeting of the Institute of Municipal Treasurers and Accountants (Incorporated), at Hastings on Monday last, but we understand that the subject is still under the consideration of the Council, and that their deliberations will not be concluded for many months. The reason for deferring the matter is that the Institute does not wish to have any friction with the other municipal departments which will be affected. From this it would appear that the timely action taken by the Incorporated Municipal Electrical Association and the Municipal Tramways Association has been effective, and it is by no means improbable that this is the last that will be heard of the Institute's proposals.

Electric Railways in Canada.—The mileage of electric railways in Canada now amounts to 992, apart from double tracks and sidings, or about double the figure for 1901. The annual gross earnings have increased from £1,154,000 to £2,801,000, and the net earnings from £467,000 to £1,062,000.

The International Exhibition at Nancy.—One of the features of the Electrical Engineering section of the International Exhibition at Nancy is a series of three stands, one in the Metallurgical Building, and two in the "Palais de l'Electricité," of the Compagnie General Electrique, of Rue Oberlin, Nancy. The most interesting exhibit in the first mentioned of these is a 750-h.p. continuous-current generator, running at 2,000 r.p.m., driven by an "Elektra" turbine. The design of the generator, which is for 250 volts, presents the features of commutating poles as well as compensating windings, and a special patent brushgear. A turbo-alternator for 250 k.v.a. at 3,000 r.p.m. The principal feature of this machine is the construction of the two-pole rotor, with its single excitation coil. A 10-h.p. petrol-driven generating set is also shown. On the other stands are shown a variety of plant and apparatus, including a mine haulage plant, fully enclosed mining motors, electrically-driven pumps, fans, and compressors. There is also a large display of continuous- and alternating-current motors, rotary converters, transformers, &c., including a 140,000-volt testing transformer. Attention should be drawn to an electric capstan, a self-contained electric hoist and a special exhibit of continuous-current traction motors with commutating poles. The smaller apparatus shown includes small transformers and miniature converters for low voltages, metal filament lamps, measuring instrument transformers, electric drills, ignition accumulator charging sets, arc lamps, switchgear, and a display of accumulators made by the company at their works at Frouard.

CATALOGUES AND PAMPHLETS RECEIVED

[Readers applying to any of the under-mentioned firms for copies of the catalogues or pamphlets referred to are requested to mention "Electrical Engineering."]

GLASS SHADES.—We have received from Messrs. Siemens Brothers Dynamo Works, Ltd. (Caxton House, Westminster), a new list giving details of their latest designs of glassware. The opening pages deal with a variety of new and select designs of glass shades suitable for high-voltage "tantalum" or metal filament lamps, which can be obtained in various types of finish at remarkably low prices. A number of shades are also illustrated which are suitable for low-voltage "tantalum" and other metal or carbon filament lamps of low voltage, in opal, satin, or crystal etched finish. Special shades, suitable for all classes of interior decorations and electric light fittings, are listed at low prices.

METERS FOR TRAMCARS.—We have received from Messrs. Chamberlain & Hookham, Ltd. (Solar Works, New Bartholomew Street, Birmingham), a booklet containing a reprint of an article by Mr. C. J. Spencer (tramways manager, Bradford Corporation), pointing out the economy in current consumption which can be obtained by checking the amount of energy used by each car. Some particulars are also given of Chamberlain & Hookham meters suitable for the work, the sole selling agents for which in the United Kingdom are Messrs. Venner & Co. (6 Old Queen Street, Westminster, S.W.).

STEAM TURBINES.—A large and handsome illustrated book is being issued by Messrs. Willans & Robinson (Rugby), containing full particulars of the design and construction of the Willans-Parsons steam turbine. The large number of illustrations of these machines in use shows at a glance the strong hold this type of turbine has obtained in this country, but perhaps even more interesting than these pictorial records of results achieved are the views of actual machinery in the Rugby works by which the blading and other parts of the turbines are produced. A detailed description of the methods of manufacture is given, the question of balancing is gone into, and scale drawings and sections are given explaining the construction of the bearings, thrust block, steam glands, steam packings, governing arrangements, lubrication, &c. Views of sets opened up show their easy accessibility, and the degree to which they have been standardised up to large sizes is clear from the outline drawings and tables of dimensions of complete turbo-alternators from 250 to 7,500 kw. and continuous-current sets up to 3,000 kw. A few remarks are included on exhaust steam or "vacuum" turbines, a subject dealt with more fully in ELECTRICAL ENGINEERING of June 3rd, page 503; and a few particulars of special condensing plant for turbines are also given. Some details of the construction of the Willans-Parsons turbine, showing how the exceptional rigidity of the blading is obtained, appeared in ELECTRICAL ENGINEERING, Vol. I., page 959.

ARC LAMP LOWERING GEAR.—A new booklet has just been issued by the London Electric Firm (George Street, Croydon), who specialise in arc lamp lowering gear. Photographs of a large number of actual installations of all the firm's special types, including central-carrier, two-stage, span-wire, and inverted gear as well as ordinary swan-neck and rectangular pillars for street-lighting are reproduced, those of the centrally-hung lamps at Grimsby, Cardiff, and elsewhere, being especially interesting. The photographs are preceded by a very complete illustrated catalogue of the various patterns of the "One Working Part" contact device and the necessary accessories. Special gear for the suspension of lamps in generating stations is also described and illustrated.

ARC LAMP CARBONS.—We have received from Messrs. W. Geipel & Co. (Vulcan Works, St. Thomas Street, S.E.), a price-list of arc lamp carbons manufactured by Messrs. Fabius Henrion, of Nancy, for whom Messrs. Geipel are sole British agents. It is said that the Henrion works are the largest carbon works in the world, and are capable of turning out one million carbons per day.

CABLES AND WIRES.—A new and very complete catalogue of cables and wires in convenient form, suitable for the pocket has been issued by Messrs. Callendar's Cable and Construction Co., Ltd. The frontispiece shows a photograph of the Erith Works, taken from a kite, and a view of the company's works at Leigh, Lancashire, is also given. There are some useful tables relating to copper conductors, and a feature of the list is the private telegraph code for transmitting inquiries, orders, and instructions. The material dealt with includes both "association" and non-association grades of single and twin conductors, vulcanised and pure rubber insulated cables, twin flexibles and electrolier wire, and various special cables, such as aerial cables, flexible trailing cables, motor-car flexibles, and twin shot-firing cables.

SOLDERING MATERIALS.—A pamphlet from Messrs. Neville, Williams & Co. (11 and 13 Southwark Street, London, S.E.) describes a new metallic soldering paste which goes under the name of "Tinol." This paste is entirely free from acid, and contains the tin-lead soldering alloy as well as the necessary flux. It is said to be particularly suitable for electrical work where good conductivity is required, besides a durable joint, and can be obtained in tins or in tubular sticks of solder. The pamphlet gives complete instructions for using the paste, and also contains particulars of a pocket soldering lamp which burns methylated spirit and produces an intensive jet of flame about four inches long. The firm has kindly sent us a sample lamp.

CONTINUOUS-CURRENT MOTORS.—We have received a new list from Messrs. Siemens Bros. Dynamo Works, Ltd. (Caxton House, Westminster), relating to continuous-current motors. Fig. 1 shows a standard protected-type machine, and the ventilated type is illustrated in Fig. 2. The latter is shown with perforated metal covers, but single- or double-gauze covers are fitted when required. In the totally-enclosed type the covers are solid The machines are designed to deal with 25 per cent.

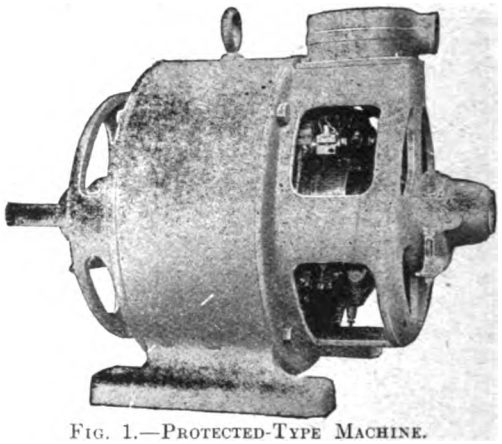

FIG. 1.—PROTECTED-TYPE MACHINE.

overload for half an hour, or 40 per cent. overload for three minutes without undue sparking or overheating. For continuous running, the temperature rise, as measured by thermometer, does not exceed 70° F. for protected-type machines, 80° F. for ventilated-type with perforated metal covers, and 90° F. in the case of ventilated-type with gauze covers, or totally-enclosed machines. All machines are designed to run at all loads with fixed position of brushes. The magnet frame is fitted with end shields which can be turned through an angle of 90° or 180°. The main poles are laminated and bolted to the frame. Commutation poles, when fitted, are of solid wrought iron in the

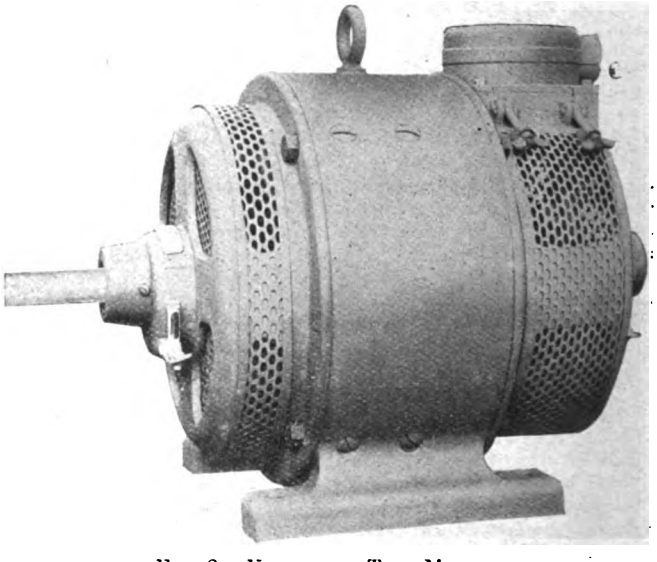

FIG. 2.—VENTILATED-TYPE MACHINE.

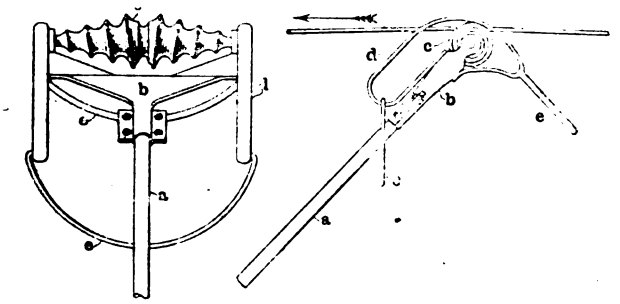
smaller sizes, and laminated in the larger sizes. The armature core plates are keyed direct to the shaft, and held in position by two end flanges. Particular attention has been paid in the design to secure thorough ventilation. Full particulars of the various sizes of motors are given in the list, the outputs ranging from 180 B.H.P. down to fractions of a horse-power. Shunt motors with speed variations up to 3 to 1, and for outputs ranging between 0·9 and 40 B.H.P. are listed, and particulars and prices of special reduction gear for motors of various sizes and for ratios up to 7·7 to 1 are given. Weights and dimensions of all the motors and accessories listed are also included.



Digitized by Google

METAL FILAMENT LAMPS.—Messrs. Falk, Stadelman & Co., Ltd. (85-87 Farringdon Road, E.C.) have sent us a copy of a new list of "Effesca" metal filament lamps, which gives notice of considerable reductions in price. The important announcement is also made that the company are introducing two new sizes of lamps that will be of great utility—namely, a 16-c.p. lamp for 100 to 130 volts, and a 32-c.p. lamp for 200 to 260 volts. The new large sizes range up to 400 c.p., which is particularly suitable for public halls, large areas, streets, &c.

ENGINEERING EDUCATION.—We have received from the University of Illinois, U.S.A., a booklet describing the School of Railway Engineering at this University. This is divided into five sections, devoted to railway civil engineering, railway mechanical engineering, railway traffic and accounting, and railway transportation. The equipment appears to be very complete, and includes a full-sized interurban electric railway car fitted with elaborate testing appliances.

NEW TRAMCAR TROLLEY WHEEL

ALTHOUGH the bow collector is in considerable use on tramways on the Continent, the trolley wheel finds more favour in this country, in spite of a tendency to leave the trolley at curves, points, and under bridges, as the wear on the wire is less with the trolley wheel. Several forms of trolley head with means to prevent the wheel leaving the wire, have been devised, and most of these comprise flexible side arms which reach over the top of the wire, but give way to span wires and other obstructions. The trolley wheel illustrated in the accompanying figure is described in the British patent No. 22,168/08, granted to F. Kompe, of Berlin, and has already been tested on the Cologne tramcars. The wheel *c* is double-conical in shape, and has two spiral grooves leading up to the running groove in the centre. The friction with the wire rotates the wheel, and the wire is always kept in the running groove, as, if it

END AND SIDE VIEWS OF TROLLEY WHEEL AND HEAD.

is jerked out on to any other portion of the wheel, the spiral formation immediately returns it to the centre. Ball bearings are provided in the fork *b*, which is constructed of sheet-iron, and fixed to the pole *a* as shown. Rigid side arms *d* are fixed to the fork *b*; the upper edges being on a level with the running surface of the middle groove. An extension is provided at each end to depress the roller if the wire leaves the central groove just before a span wire. The object of the arms is to prevent the wheel being thrown off the wire altogether, as when the wire is jerked out of its central position it strikes one of the two arms, and rebounds on to some portion of the spiral groove. In ordinary circumstances the arms do not come in contact with the span wires and other obstructions. When the car is running on a single-track section with the two trolley wires close together, the lower portions *e* prevent the second wire from being jerked under the arms *d*.

Tramway Speed Indicators.—As will be seen in an advertisement on another page, the Council of the Tramways and Light Railways Association have made arrangements, with the co-operation of some of their members, who are owners of tramway undertakings, to make a series of trials of any speed indicator of merit, that may be brought to their notice as a useful addition to the ordinary equipment of a tramway car. The Council invite communications from any owners, inventors, or manufacturers who may desire to take advantage of the opportunity so afforded them.

Electric Traction in Hungary.—According to the *Elektrotechnischer Anzeiger*, the Hungarian State Railway authorities have decided to convert the Fiume-Kameral-Moravicza section of the Budapest-Fiume line to electric traction. Electric power will be obtained from a supply company who have a large supply of water-power near Zengg. It is stated that a group of French financiers are finding the necessary capital of £1.250.000. A report on the country's water-power, prepared by the hydrographical department of the Hungarian Ministry of Agriculture, states that there is about 1,700,000 h.p. available for utilisation.

STEAM v. ELECTRIC TRACTION

ON Thursday, at the Royal Institution, Prof. W. E. Dalby delivered the second of his two lectures on this subject; an abstract of the first lecture was published in ELECTRICAL ENGINEERING of June 10th, page 530. Considering, in the first place, the design of locomotives, the lecturer pointed out that the best design was a compromise between the engine most suitable to produce a steady pull to overcome the tractive resistance when running, and that which would start and accelerate under the severest conditions. The tractive resistance, or the drawbar-pull necessary to keep a train running at a constant speed, could be taken as from 4 to 5 lb. per ton weight of train at a speed of 10 m.p.h., 14 lb. per ton at 50 m.p.h., and 36 lb. per ton at 100 m.p.h. On the Zossen experimental line, a pull of 46 lb. per ton at a speed of 112 m.p.h. was measured. These figures were for vehicles; for engines the values were larger.

For a 300-ton train drawn by an 80-ton steam locomotive at a speed of 50 m.p.h., the total tractive force, the lecturer said, would be $300\times14+80\times27=6,360$ lb., and to exert this at a speed of 50 m.p.h. (73·4 ft. per sec.), an engine of $6,360\times73{\cdot}4\div550$, or 850 h.p. would be required. The i.h.p. would be about 950 h.p., and at 26 lb. of steam per i.h.p.-hour, some 2,470 gallons of water would have to be evaporated per hour. Assuming that 8 lb. of water were evaporated per lb. of coal, 1·38 tons of coal would be consumed every hour. For an electrically-propelled train the total tractive force would be 300×14, or 4,200 lb. A glance at the characteristic curves of a 150-h.p. motor showed that, at a speed corresponding to 50 m.p.h., a pull of 1,080 lb. was exerted. Four of these motors, then, would give somewhat more than the desired tractive force at that speed. If this pull was to be exerted for a period longer than one hour, it would be necessary to see that the rate at which the motors were working was below the one-hour rating. The pull of a steam locomotive with a given evaporating capacity decreased rapidly with increasing speed, and was strictly limited. In the case of an electric motor, however, a large torque could be exerted over a very wide range of speed, and very high values could be obtained for short periods.

Turning to the question of starting and accelerating, the lecturer emphasised the importance of the energy stored in a moving train. To change the speed of a train from 20 to 25 m.p.h., only 750 ft.-tons of energy were required per 100 tons of train, but to increase the speed by the same increment at 60 m.p.h., some 2,000 ft.-tons were required. Prof. Dalby worked out the example of a 10-mile run with (*a*) no stop, and (*b*) a stop every half mile, at the same average speed. This showed that about double the energy was required to run the train in the latter case, owing to the large amount required to accelerate. A large quantity of power could be developed by a small equipment of motors during short periods, and it was this property of the motor that rendered electric traction inevitable for systems with frequently stopping trains, as the trains could be brought to speed much quicker than was the case with steam traction. Moreover, owing to the ease with which electric trains could be handled in termini, the electrification of any given system amounted virtually to an increase in the size of the stations.

South African Exhibition.—The South African National Union has decided to hold an exhibition shortly in Capetown. The exhibits will include electrical apparatus and machinery, motor-cars, and other engineering appliances. All countries are invited to exhibit.

Buenos Aires International Exhibition.—In connection with the centenary of Argentine Independence, an International Exhibition of Railways and Land Transport will be held in Buenos Aires from May to November, 1910. The date before which application for space must be made in Buenos Aires has been postponed to September 10th, 1909, and to the exhibition delegates abroad, to August 10th, 1909. The date for applying for erection of special kiosks has also been postponed up to July 25th next. A pamphlet in English giving the charges for registration and space and information of interest to prospective exhibitors has been issued by the Executive Committee.

Another Proposed Tax on Electric Lamps in Germany.—In spite of the fact that the proposal of the German Government to tax electrical energy and electric lamps was so strenuously opposed, and eventually came to nothing, a similar proposal, referring to lamps only, has been made by the recently appointed Finance Commission. The main features of the original Bill were given in ELECTRICAL ENGINEERING of November 19th, 1908, Vol. IV., page 677. For filament lamps of high candle-power, the latest charges are higher than those previously proposed, and there are modifications in the charges on carbons, the quality being taken into account. It is very doubtful, however, that anything will come of this second proposal.

CORRESPONDENCE

STEAM v. ELECTRIC TRACTION FOR MAIN LINE HAULAGE.

To the Editor of ELECTRICAL ENGINEERING.

DEAR SIR,—I have read with great interest the report in your last issue on the lecture by Prof. W. E. Dalby on the above very important subject. His remarks concerning two towns 100 miles apart are open to some question, as they are no doubt based on a comparison between the steam locomotive and ordinary electrification, but there is one method that has possibly not been considered in this connection, and that is the use of the internal combustion engine as a power-producer for train haulage. It has been my pleasure to investigate this matter very closely during recent years, and it is my firm opinion that in the very near future some very startling results will be witnessed on the trials of this method of propulsion being made public. This prime mover embodies the important commercial characteristics of high thermal and mechanical efficiency, with consequent economy, simplicity, and strength of its few working parts, low water consumption, low weight, long life, and comparatively silent working, and it is generally suitable for use with an approved system of power transmission and speed regulation for propulsion of self-contained passenger and freight trains.

The great advantages of electric traction in the way of unlimited hauling capacity with multiple unit control from the head of the train under control of one man, rapid acceleration, maintenance of maximum tractive power, reduction of the time lost in turning and other light operations at terminal stations, the elimination of smoke, gas, and cinders, are, nevertheless, largely over-balanced by the steam locomotive in its decreased first cost, and expense of operation, the flexibility and reliability of service obtained by a self-contained machine, generating its power necessary to develop its own hauling capacity, its adaptability for varying speeds and power, its ability to operate over varying track conditions with safety. Its use also eliminates considerations of load factor, losses and complication due to independent current producing, and distributing systems.

But when it is compared with its more efficient brother, the internal combustion engine, it will stand a very poor chance, especially when the acknowledged drawbacks, such as irreversibility and invariability of speed, can be satisfactorily got over by application of electrical power transmission. The application of this method would not require any alteration of existing tracks, telephonic or telegraphic local circuits, and would entail considerable decrease in fuel, haulage costs, and water supply. Much more can be said in favour of this internal combustion-electrical method of main line train haulage, and electrical engineers need not die with disappointment at the lecturer's remark that a speed of 50 miles per hour cannot be economically maintained between two towns 100 miles apart by other method than by the steam locomotive, as this is not quite correct when taking into account the possibilities of electrical power transmission in this large and most important field.

I am, Dear Sir,
Yours faithfully,
WILLIAM P. DURTNALL.

The Paragon Electric Power Transmission Co.,
11 Bush Lane, E.C.
June 12th, 1909.

STREET LIGHTING AT BRADFORD.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—With reference to the articles on the street lighting at Bradford contained in your issues of June 3rd and 10th, I consider that Mr. Roles deserves the thanks of all interested in street illumination for publishing the measurements he has made, which are of very considerable value to those who treat the subject seriously.

It is true the first article is somewhat misleading owing to the curves being the aggregate of the readings in direct illumination, and not horizontal illumination derived from all sources. But, as I have previously stated in print, I think the value of a direct illumination curve—such as is given in Fig. 3—is considerable, as a curve of horizontal illumination can be easily plotted from it. I might mention here that Fig. 3 is evidently direct illumination obtained from Fig. 2, and not on a horizontal surface as you presume (direct illumination being equal to c.p. divided by slant distance squared, horizontal illumination being equal to c.p. multiplied by height of lamp divided by horizontal distance cubed).

There are certain other particulars which would greatly increase the value of the curves if you would kindly publish them. For instance, (1) what type of gas lamps were used, as it appears from Fig. 1 (June 10th) that the candle-power of the rays decreased between 70° and 30° from the horizontal, whereas with all types of gas mantles (except inverted) the candle-power increases considerably as the rays approach the horizontal. Moreover, using this curve, I cannot get the results given for the gas in the curve published June 3rd. (2) With reference to the arc lamps, granting that all the light derived from an Excello arc lamp emanates from the lower hemisphere, how does Mr. Roles account for the fact that Fig. 2 shows an increase of mean hemispherical candle-power with the special dioptric globe? I have averaged these curves, and find that the mean hemispherical candle-power is as follows:—

(1) With special dioptric inner globe and thick opalescent outer globe	1,816
(2) With pear-shaped opalescent globe	1,630
(3) With reflector and pear-shaped opalescent globe	1,942

The reflector has increased the mean hemispherical candle-power due to its reflecting rays diverted from the lower hemisphere by the opalescent globe, but it seems incomprehensible that the use of an extra dioptric globe, which diverts but must also absorb some of the rays, should increase the mean hemispherical candle-power, though, of course, it increases the candle-power in the desired direction.

I think Mr. Roles's statement that "a more even illumination was naturally provided by the gas," and that "the portion of the road midway between the posts (arc) looked darker in comparison," accounts for the Sub-Committee's decision. I therefore would suggest that it is a pity he did not follow the same lines as the gas company, using tungsten lamps at short intervals. If this had been done, the cost, both capital and maintenance, would probably have been less for a better and more even illumination.

That long, narrow areas, such as streets, can be lighted more economically by small units than by large ones must be admitted, and now that these small units of light can be efficiently produced, it is likely that the large units will be relegated to open spaces and similar positions.

Yours faithfully,
HAYDN HARRISON.

DEVELOPING ELECTRIC SUPPLY ON THE NORTH-EAST COAST

THE Durham (County) Electric Power Bill was before the Unopposed Committee of the House of Commons on Thursday, and was ordered to be reported for third reading. The main proposal of the Bill was authority to link up the power stations of the County of Durham Electric Power Supply Co., the Newcastle Electric Supply Co., and the Cleveland & Durham Electric Power Co. To this no exception was taken. Clause 17, however, which provided that the company may invest its funds in other industrial concerns to the extent of one-tenth its capital expenditure, was unanimously opposed by the Committee, and eventually rejected. Mr. C. H. Merz, giving evidence in support of the clause, explained that the object was to encourage firms either to convert their works to electric driving, or to erect new works in the areas of the power companies. The clause would enable the power companies to take shares in such companies in order to provide funds for these purposes, a procedure which was regarded as more satisfactory than lending apparatus on hire. On the ground that it was not politic to allow Parliamentary companies to go beyond their legitimate sphere of trading, the Committee, as stated above, rejected the clause.

Curious Accident on the Sheffield Tramway System.—On Saturday last, a motor car skidded in endeavouring to avoid a tramcar, and collided with a section box belonging to the Pitsmoor-Firth Park section of the Sheffield tramways, which it cut clean away at the base, severing the cables. Although the resulting short-circuit caused the sub-station circuit-breakers to disconnect the cables, the section-box caught fire. The occupants of the car were uninjured, and the car itself was so little damaged that it was driven home. After the feeders had been isolated, the dead section was connected to the adjacent Brightside section, and the tramway service restored. Sufficient current could not be obtained in this way, however, to supply the full number of cars, but a reduced service was maintained until the box was repaired.

Railway Amalgamation.—The President of the Board of Trade has appointed the following Committee to consider and report as soon as practicable what changes, if any, are expedient in the law relating to agreements among railway companies, and what, if any, general provisions ought to be embodied for the purpose of safeguarding the various interests affected in future Acts of Parliament authorising railway amalgamations or working unions: Mr. Russell Rea, M.P., Chairman, Lord Robert Cecil, M.P., Sir Maurice Levy, M.P., Mr. G. H. Roberts, M.P., Lord Hamilton of Dalzell, Lord Newton, Mr. J. S. Beale, Mr. Alexander Siemens, Mr. Ernest Moon, and Mr. W. Temple Franks.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published June 10th, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.
Names in italics indicate communicators of inventions from abroad.

10,535/08. **"Liconite" Cables and Insulating Materials.** E. S. ALI COHEN, P. A. CRAMER, and W. GEIPEL. This specification relates to the manufacture of "Liconite" cables, some tests on which were described in ELECTRICAL ENGINEERING of May 28th, 1908, Vol. III., page 803. Paper tape is passed through a bath of paraffin, and then coated with a bituminous composition comprising about 63 per cent. of purified asphalte, 18·4 per cent. of solidified petroleum, and 18·6 per cent. of liquid paraffin. The treated paper is wound spirally over the cable, alternately with layers of a similarly impregnated textile tape. An alternative method consists in rendering the bituminous composition elastic, as described in specification No. 5,279/08, and rolling and cutting the product into tape without the addition of paper. Such a cable can be vulcanised afterwards if sulphur has been added to the composition. To avoid decentralisation, layers of textile tape may be wound between the layers. Eight claims.

10,891/08. **Metal Filaments.** WOLFRAM LAMPEN AKT. GES. A process for decarbonising metal filaments is described. The filaments are brought to a red heat by the passage of a current in an atmosphere of hydrogen and sulphuretted hydrogen. The latter is decomposed, the sulphur combining with the carbon in the filament, while the free hydrogen reduces any metallic sulphide that may be formed. The gases should be at a greatly reduced pressure, and free from air and moisture. Two claims.

17,621/08. **Metal Filaments.** W. D. COOLIDGE. Fine tungsten powder reduced from tungsten trioxide is mixed with a binding agent, consisting of 42 per cent. cadmium, 53 per cent. mercury, and 5 per cent. bismuth. The product, containing from 30 to 40 per cent. of tungsten, is squirted into rods, which are drawn into filaments, or is squirted into filaments directly. These are baked in an open furnace for from 15 to 45 minutes, and then fired in a furnace until all except the tungsten is evaporated, and the latter sintered to the required degree. For this last treatment, the filaments are placed in graphite boats and raised to a temperature of about 1800°C. in the presence of hydrogen. A special form of boat and furnace is described in the specification. Three claims, two figures.

27,144/08. **Metal Filaments.** A. KROLL and B. SAKLATWALLA. In squirting the filaments, a double die composed of two dies placed coaxially, is used. The outer die is fed with collodion gelatinised in alcohol-ether, and the inner die with the metallic paste. Colloidal tungstic acid may be used, as the collodion coating is impervious to water, and prevents the filament loosing its water and getting inflexible before the sintering treatment. The outer die protrudes over the orifice of the inner one, and the metallic core can be compressed by adjusting the pressure of supply, and a fine filament produced without using a fine die. Four claims.

27,477/08. **Inverted Insulated Third Rail.** P. M. JUSTICE. *(Essex Co., U.S.A.)*. The insulator consists of two parts, each provided with a flange which fits under the top flange of the rail, the latter being I-shaped in cross section, with a contact flange along the bottom. The insulator is rigidly bolted to a bracket. Six claims, three figures.

8,443/09. **Arc Furnace for Production of Nitric Oxide.** SALPETERSÄURE INDUSTRIE GES. This furnace is similar to the Badische Anilin- und Sodafabrik furnace described in ELECTRICAL ENGINEERING of June 3rd, page 515, in that an arc in a long tube, without any magnetic control, is used. Instead of the air being blown straight through, a series of air inlet and gas discharge orifices, alternating with each other, are provided. The velocity of the air is thus reduced, and by conducting away separately the gas from the region near the electrodes, the impurities due to the evaporation of these are not mixed with the main gas current. The annular elements of the furnace are composed of fire-brick, and contain coils to cool the gases. Four claims, two figures.

Opposition to Grant of Patents

2,720/07. **Electric Ignition Apparatus for Miners' Lamps.** W. PATTERSON. Opposition was entered to the grant of this patent, and the Comptroller's decision required an amendment of the specification. On appeal, the grant was allowed. The patent covers an arrangement whereby the current cannot be switched on when the door of the ignition chamber is open.

28,636/07. **Galvanising Apparatus.** S. O. COWPER-COLES. The opposition to the grant of this patent (*see* ELECTRICAL ENGINEERING of April 1st, 1909, page 311) has been unsuccessful.

2,261/08. **Arc Lamp with Disc Carbons.** A. HOLMAN. The opposition to the grant of this patent (*see* ELECTRICAL ENGINEERING of May 13th, 1909, page 452) has been withdrawn.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free.
Names in italics indicate communicators of inventions from abroad.
Summaries of some of the more important of these patents will appear in our next issue.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: SIMPSON and BROWN [Apparatus for impregnating insulation with varnish] 9,090/08; RAYNER and CHILLINGTON TOOL CO. [Cable connectors] 16,060/08; BEAVER and CLAREMONT [Apparatus for use with cables] 2,076/09.

Dynamos, Motors, and Transformers: ELECTRIC CONSTRUCTION CO. and BUCHANAN [Machines for fluctuating loads] 11,5[illegible]; PARSONS and LAW [Commutators] 11,871/08; BURLEIGH [Machines] 15,487/08.

Electric Ignition: WILLIS (*Mildebrath*) [Ignition device for internal combustion engines] 868/09.

Electrometallurgy and Electrochemistry: GIBBS [Manufacture of articles by electro-deposition] 4,410/08; HEINTZ [Bunsen cell] 13,671/08.

Instruments and Meters: KLINGELFUSS [Measurement of induction-coil currents] 11,299/08.

Switchgear, Fuses, and Fittings: THOMAS [Circuit-breakers] 11,183/08; BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*) [Switchgear] 11,345/08; MYGATT [Lamp reflector and shade] 11,539/08; BARLOW [Motor-controlled switches] 12,508/08; WHITE [Fuses] 17,170/08; HATRY [Fuses fitted with indicating device] 2,353/09; GILES [Excess-voltage safety device] 4,997/09; SIEMENS BROS. DYNAMO WORKS (*Siemens & Halske Akt.-Ges.*) [Fuse fittings] 8,263/09.

Telephony and Telegraphy: BROWN [Telephony and telegraphy] 11,135/08; NICHOLSON [Telephones] 6,523/09.

Traction: CUMMINGS and NOREAU [Locomotive alarm systems] 27,923/08; BRYAN [Trolleys and collectors] 747/09; LEDER [Rail bond] 7,635/09.

Miscellaneous: DARRAH and HACKETT [Lighting of roundabouts] 11,758/08; PÜRTHNER, ZIMMERL and BÖCK [Electro-therapeutic apparatus] 16,772/08.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

BISSONNETTE [Alarm for portable boxes] 10,747/09; PATTERSON [Batteries and battery-holders] 11,154/09.

Expiring and Expired Patents

The following Patents expire during the current week after a life of fourteen years:—

12,018 of June 20th, 1895. **Electrolytic Reduction of Metallic Oxides.** L. MOND. Oxides, such as zinc oxide, are dissolved in caustic alkali, and an amalgam with mercury of the same alkaline metal as that in the solution is introduced as the anode. An iron or zinc cathode is used, and the metal of the oxide is deposited on this.

12,229 of June 24th, 1895. **High Resistance Units.** H. J. VOIGT and J. A. HAEFFNER. A coating of metal in a finely-divided state is produced on porcelain or glass, by precipitation, painting, or reduction of metallic oxides. The metallic layer can be afterwards strengthened electrolytically.

The following are the more important Patents that have become void through non-payment of renewal fees.

Electric Ignition: J. & G. KEITH [Ignition of gas lamps] 4,518/03; W. BEST [Ignition of miners' lamps] 4,618/03.

Electrometallurgy and Electrochemistry: ELECTRIC REDUCTION CO. (*W. T. Gibbs*) [Incandescent carbon rod furnace] 4,819/98; H. NEHMER [Primary cell] 4,512/04.

Instruments and Meters: LORD KELVIN [Core and solenoid ammeter] 4,207/96.

Switchgear, Fuses, and Fittings: A. C. EASTWOOD [motor controller with integral resistances] 4,507/04.

Telephony and Telegraphy: J. S. STONE [Multiple-gap discharger for wireless telegraphy] 29,142/04, and [Tuning receiver circuits] 29,143/04.

Traction: F. H. DANIELS [Rail bond] 4,824/97; A. J. BOULT (*N. A. Christensen*) [Air-brake system for multiple-unit trains] 3,985/01; A. DUPPLER and A. GREEN [Combined hand and electric brakes] 4,311/01; J. C. WHITE & Co. and I. H. FISHER [Casting conduits and boxes for conduit traction system] 4,675/03; CONSOLIDATED ENGINEERING CO., and H. E. BROWN [Vacuum brakes] 4,604/04; A. K. BAYLOR [Tramcar route-indicator] 5,005/04 and 5,006/04.

Miscellaneous: H. J. HAYS [Electric heating of glass cylinders during manufacture] 4,501/04; H. NEHMER [Portable lamp] 4,512/04.

Patent Record	594

"Electrical Engineering," although the Cheapest Electrical Paper (Price **1d.** weekly), contains the Most Useful and Practical Articles, the Best Illustrations, and the Latest News. It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.

SUMMARY

The hearing of the action brought by the British Westinghouse Co. against Mr. G. Braulik for alleged infringement of the Bremer patent covering the horizontal adjustment of the carbons in converging carbon arc lamps, was commenced on Tuesday. Mr. Braulik denies infringement, and disputes the validity of the patent on the ground of anticipation. The mechanisms of the alleged anticipations were discussed yesterday. Both Mr. J. Swinburne and Mr. Dugald Clerk affirmed that none of them effected a to-and-fro horizontal adjusting motion in between the periods of feeding, as given by the Bremer mechanism. (Page 571.)

The small generating station of the Chichester Electric Light & Power Co., which was inaugurated a few weeks ago, is of interest as being the first generating station to be equipped with Diesel engines of British design and manufacture. At present two 150-h.p. engines are installed, driving continuous-current generators. The only other electrical plant is a 25-kw. balancer, but provision is made on the switchboard for a battery should this be added later on. (Page 572.)

An illustrated article deals with the application of the Curtis turbine to exhaust steam and mixed pressure working, and gives some results of tests of an installation at a colliery in Scotland. (Page 574.)

The new garage of the Brighton, Hove & Preston United Omnibus Co., which has been established for the electric accumulator omnibuses which the company are now running, contains a special charging equipment on the Stevens system, in which regenerative reversible boosters are used in each battery circuit to avoid waste of energy in resistances. (Page 576.)

Mr. H. H. Couzens (Deputy City Electrical Engineer, Bristol) has been appointed Borough Electrical Engineer at West Ham to succeed Mr. H. H. Seabrook.—Comparative trials of gas and electric street lighting are being held in Bath.—The electricity accounts at Birmingham show a net balance of £10,000.—A surplus of £4,263 is shown by the Islington Electricity Department.—The Board of Trade have intimated that they have no power to institute an inquiry into the surface-contact tramways on the Mile End route.—A gross profit on the Manchester Corporation

Digitized by Google

electricity undertaking for the last year has been £161,706, this giving a net surplus of £12,000 after deducting capital charges. (Page 576.)

TENDERS for cables are required for Acton and Worksop, and mains extensions are to be put down at Hackney. The Local Government Board have sanctioned a loan of £2,450 for plant extensions at Llandudno. Local Government Board inquiries have been held at Bath (£11,700), Bexhill (£2,120), Salford (£2,200), and Southampton (£3,600). The tender of Messrs. Hurst, Nelson & Co. for 200 new electric cars for the London County Council tramways is recommended for acceptance, and the tender of the Westinghouse Co. for the electrical equipment. An order has been placed with the Lancashire Dynamo & Motor Co. for a 1,000-kw. generating set for Partick. (Page 578.)

THE report of the Marconi Wireless Telegraph Co. states that the Clifton station (Ireland) is now complete, and it is anticipated that the dividend-paying period will speedily be entered upon. (Page 580.)

MR. PEARCE'S Presidential Address to the Incorporated Municipal Electrical Association on Tuesday dealt with a large number of topics of current interest, notably with the cost of power supply and the methods for cheapening house-wiring. On the former question he pointed out that the new plant added to the generating station to deal with additional power supply costs now per kw. only from one-half to one-third the cost of the existing plant, so he thought it should be equitable to remit a proportion of the fixed charges on capital in the case of new power consumers. On the question of wiring, he is of opinion that the use of flexibles at a proper height on the surface need not lower the standard of safety, and that the number of lamps allowable per circuit might be increased.—Councillor Alex. Sinclair's Paper on "Cheap Units" gave rise to a long discussion, in which interest was maintained to the end. Mr. Sinclair put forward a method of calculating the charge for power supply from the consumer's load-factor, which was criticised by a number of speakers. The majority of the speakers objected to varying the price of power supply to different consumers except in the case of very large ones. The restricted-hour method was also discussed by Mr. Sinclair and others, and found an ardent supporter in Mr. A. M. Taylor, who opened the discussion with his characteristic vigour.—Both in the Lord Mayor's welcoming speech and in Councillor Royse's speech at the luncheon on Tuesday, the question was raised as to whether municipal electricity undertakings should make a profit in relief of rates.—Two Papers were read yesterday: Mr. E. E. Hoadley dealt with the metallic filament lamp question. At present the A.C. stations have suffered most by the drop in output due to the higher efficiency of the lamp, as the consumer can, by employing a transformer, have the same light as hitherto at a less consumption. The D.C. 200-volt stations will, Mr. Hoadley thinks, suffer in the near future, when lamps of smaller candle-power are available and the prices are reduced. He recommends them to push the heating and cooking business, if possible with the aid of free wiring and hiring out heating and cooking apparatups if they can get powers. The latter part of the Paper dealt with the suitability of the new lamps for street lighting, and mentioned the author's experience that these lamps had an average life of 1,100 hours, individual lamps lasting from 5,000 to 6,000 hours. Our report of the discussion on this Paper will appear in our next issue.—The second Paper was on "Modern Cable Systems," by Mr. E. M. Hollingsworth. It reviewed generally the various methods of laying cables, noting from experience the technical details to be observed and the dangers to be avoided. A description was also included of the overhead work and the subway at St. Helens, and a useful table was given showing the relative costs of the "direct in ground," "solid," and "draw-in" systems. (Pages 581 to 588.)

A MANSION HOUSE meeting will be held early next month to consider the want of confidence that exists between capital and the electrical industry of this country. (Page 589.)

A DESCRIPTION is given of a form of link for chain-grate stokers, which can easily be replaced in case of breakage without shutting down the boiler. (Page 589.)

A NEW pattern of switch-fuse box, in which the heads of the fuse-carriers form the moving contacts of the switch, has been put on the market. (Page 590.)

THE adjourned Local Government Board inquiry into an application of the West Ham Corporation for sanction to borrow £51,600 and £23,000 for the purposes of the electrical undertaking was held last week, and the Corporation officials once again refused to make public the details of specific contracts, &c. After a two days' hearing, the inquiry was adjourned until July 5th. (Page 591.)

A LETTER in our correspondence columns makes some criticism on the conclusions expressed by Mr. R. Nelson in his recent Paper on "Electricity in Coal Mines" before the Institution of Mining Engineers. (Page 593.)

AMONG the specifications published by the Patent Office on Thursday last was one by Bertram and E. Thomas for a double-pole solenoid-operated circuit-breaker. The Electric Construction Co., Ltd., and W. Buchanan have one for a D.C. load equalising system comprising an auxiliary motor and a flywheel on the main motor. The auxiliary motor is excited by the current taken by the main motor, and, when the latter is overloaded, operates a rheostat in the shunt circuit so as to reduce the speed of the main motor and take energy from the flywheel. A method of ensuring equal division of the load amongst D.C. generators running in parallel, by providing each machine with a Tirrill regulator fitted with additional coils, is protected by the British Thomson-Houston Co.; and C. A. Parsons and A. H. Law have patented a form of construction for the commutators of turbo-generators. Specifications relating to impregnation of insulation with varnish, a primary cell, and a fuse-holder, respectively, are also abstracted. Opposition has been entered to the grant of patents to T. Wardell for a double armature magneto-generator, and to Siemens & Halske Akt.-Ges. for a ductile tungsten-nickel alloy suitable for drawing into filaments. (Page 594.)

A SUBJECT which is perennially discussed at Manchester, and indeed in many other cities, is the correctness of allocating large profits from municipal electricity undertakings to the relief of the rates. Speeches on Tuesday by the Lord Mayor of Manchester and Councillor Royse respectively expressed the two opposite views. On the one hand, it is argued that as the ratepayers' money had been risked in the undertaking, they should have profits just as would shareholders in a company, as they have to make good the deficit if one arises. On the other hand, the argument is at any rate equally good that the ratepayers do not actually provide the capital, nor do they pay interest on it; the undertaking itself is debited with the interest and sinking fund, and the object in Parliament having permitted this form of municipal trading was not to relieve the rates, but in order that the consumers might derive the benefit by buying their electrical energy at cost price. The position is certainly the more logical one, and the only objection to be taken to it is that during the first few

Digitized by Google

years a municipal electricity works are usually unremunerative, and the loss has actually to be made good by the rates each year, as it is not allowable to carry the deficits to a suspense account. To meet this objection, however, two obvious courses are open. As soon as the undertaking commences to pay its way, after proper sums have been put by to reserve and renewals funds, balances may be paid over in relief of rates yearly until the previous deficits have been repaid to the ratepayers with a reasonable rate of interest; then the time comes for the selling price to be reduced, so that the profit should be nil. The alternative is to pay a small sum in relief of rates each year equivalent only to a fair interest upon the previous deficits, regarding these as capital contributed by the ratepayers. The former method is the more equitable, as it repays the entire amount of the deficits to the same generation of ratepayers upon which they originally fell. For a "reproductive" municipal undertaking to pay year by year large sums in relief in rates far in excess of any levy that may have been made in past years to pay deficits is practically penalising the ratepayers who are consumers for the benefit of those who are not.

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, JUNE 24TH.

Incorporated Municipal Electrical Association.

10 a.m. Meeting at the Manchester Municipal School of Technology, Whitworth Street. Papers to be read: (1) "Steam Turbines from the User's Point of View," by A. S. Blackman (Sunderland); (2) "Notes on Condensing and Water Cooling Plants," by E. Lunn (Huddersfield).

2.30 p.m. Visit to the Westinghouse Co.'s Works.

6.30 for 7 p.m. Annual Dinner at the Midland Hotel.

FRIDAY, JUNE 25TH.

Incorporated Municipal Electrical Association.

10.30 a.m. Annual General Meeting at the Manchester Municipal School of Technology, Whitworth Street, for the election of Council and Officers for the 1909-10 Session.

2.30 p.m. Visit to the Frederick Road power station of the Salford Corporation.

TUESDAY, JUNE 29TH.

Faraday Society.

7.45 p.m. Annual General Meeting at the Institution of Electrical Engineers, 92 Victoria Street, London, S.W. At the ordinary meeting at 8.15 p.m., the following Papers will be read:—(1) "Researches on the Relative Rates of Migration of Ions in Aqueous Solution," by R. Denison; (2) "Apparatus for the Rapid Electro-analytical Separation of Metals," by H. J. S. Sand; (3) "The Conditions which determine the Composition of Electro-deposited Alloys," by S. Field.

WEDNESDAY, JUNE 30TH.

Institution of Electrical Engineers.

9 p.m. Annual Conversazione at the Natural History Museum, Cromwell Road, London, S.W.

THE BREMER FLAME ARC LAMP PATENT
Hearing of the Action for Infringement

THE hearing of the action brought by the British Westinghouse Co. against Mr. G. Braulik for alleged infringement of the Bremer flame arc lamp patent, of which they are the owners, came before Mr. Justice Joyce in the Lord Chancellor's Court on Tuesday. Mr. A. J. Walter, K.C., and Mr. E. Russell Clarke are appearing for the Westinghouse Co., and Mr. W. R. Bousfield, K.C., and Mr. J. Hunter Gray for Mr. Braulik. Expert evidence is being given by Mr. J. Swinburne and Mr. Dugald Clerk on behalf of the Westinghouse Co., and by Prof. S. P. Thompson and Prof. J. D. Cormack on behalf of Mr. Braulik.

The patent in question is No. 18,786 of 1902, granted to H. Bremer, and relates to the feeding of the carbons in arc lamps of the converging carbon pattern. The patent—which was amended in December, 1907, when one of the claims was struck out and a disclaiming note added—describes mechanism for the purpose of obtaining a lateral movement of one or both carbons in addition to the downward feeding motion. Two alternative mechanisms are described in the specification. The first consists of an arm which bears against one carbon. An armature attached to the upper end is attracted by an electro-magnet connected in shunt across the arc, and this end also holds the detent, which engages with a star-wheel geared to the feeding-cord drum. If the arc lengthens, the armature is attracted to the magnet, and the swinging carbon pushed towards the other carbon, and this action is continued until the armature has moved to such a point that the star-wheel is released. Feeding then takes place. In the second mechanism, the swinging carbon is moved by means of a loose collar near its burning end, this movement being controlled by a vertical shaft which is given a rotary motion by means of the differential action of shunt and series coils.

The single claim attached to this specification is as follows:—

An arc lamp having downwardly pointing electrodes and provided with both downward and horizontal feed mechanism, so arranged that a certain amount of operation of the horizontal feed mechanism takes place before the downward feed mechanism is permitted to operate, subject to the disclaiming note.

The disclaiming note reads as follows:—The lamps to which my invention applies are of the type in which the current is supplied to the electrodes through electrode-holders, in which the upper ends of the electrodes are firmly clipped, and which are capable of being lowered simultaneously through the same distance, and about one of which the corresponding electrode can swing under the action of a device acting near its lower end, and I limit my claim to lamps of this description.

Mr. Braulik not only denies the alleged infringement, but disputes the validity of the patent on various grounds. He claims that the invention was contained in several previous patents, and quotes thirteen specifications in support of this—six British, one French, five American, and one German. Secondly, he affirms that it is impossible to construct a practical lamp from the description and figures given in the specification, and that the new parts are not distinguished from the old. Finally, he asserts that the complete specification claims more than that described in the provisional, in that the latter does not refer to a device for effecting the horizontal movement of the electrode, and acting near its lower end. This feature was not novel at the date of the complete specification, he asserts, but was described in Patent No. 23,606 of 1902, granted to P. Högner previous to the filing of Bremer's complete specification.

In opening the case for the Westinghouse Co., Mr. WALTER stated that the patent in question covered an arc lamp with (*a*) downwardly pointing electrodes inclined to each other; (*b*) holders through which the current was supplied, and which firmly gripped the electrodes; (*c*) a downward feed in which both carbons were lowered simultaneously through the same distance; (*d*) a horizontal feed effected by swinging one electrode by means of a device acting near its lower end; and (*e*) a downward feed retarded until a certain amount of horizontal adjustment had taken place. All these features had, he said, been infringed by Mr. Braulik.

Mr. SWINBURNE, giving evidence on behalf of the Westinghouse Co., described the invention, stating that for steady burning, and, especially with flame arc lamps, it was most important that the lateral movement of the carbons should be independent of the downward feed. He admitted that the drawings accompanying the specification were not correct, but asserted that there would be no difficulty at all in making a lamp from these and the specification. There was no disconformity between the provisional and complete specifications. He did not find that the invention was described in any of the prior patents mentioned. Mr. Braulik's lamp, the "Eclipse" flame arc lamp, was essentially the same as that covered by the patent; it differed only in minor respects, such as the use of a brake-wheel instead of a detent. Models of the two mechanisms described in the specification had been made (these were exhibited in court), and he had found that they worked. Cross-examined by Mr. BOUSFIELD, he agreed that lamps with a backward and forward motion of the carbons irrespective of the feed were well known previous to the date of Bremer's patent, but asserted that in all cases the adjusting motion was in the direction of feed, and not horizontal, as in the Bremer lamp. He also agreed that if the disclaiming note were neglected, the only features left were those denoted (*a*) and (*e*) by Mr. Walter—namely, downwardly inclined electrodes, and a downward feed retarded until a certain amount of horizontal adjustment had taken place.

Mr. Bousfield then referred to the U.S.A. patent No. 268,218 granted to A. Graham in 1882 for an arc lamp with inclined carbons, one of which was pivotted and swung by means of a lever. An armature fixed to this lever was attracted by a

Digitized by Google

magnet against the pull of a spring, and when the pull of the magnet (which was in shunt across the arc) drew the armature up to it, a detent was released and the carbons fed down. Mr. Bousfield claimed that the features (*a*) and (*e*) were included in this invention, as the armature would float and adjust the arc between the periods of feeding. Mr. Swinburne asserted that the armature would not float, but would stick to the magnet core, falling away only when the current was much reduced, to allow feeding, but Mr. Bousfield pointed out that it was mentioned in Graham's specification that a solenoid and core could be used instead of the electromagnet, and this, he asserted, would allow the lever to float and adjust the arc. Moreover, the same might be said of the first of the two mechanisms described in Bremer's specification. Mr. Swinburne asserted that, previous to Bremer's invention, an arc lamp maker would not have tried to make the lever float, and in reply to this Mr. Bousfield said that in the Serrin, Crompton, Siemens, Brockie, and other lamps before 1882 there was a floating armature. Mr. Swinburne agreed that this was so in the case of vertical carbon lamps only.

After referring to several of the patents quoted as anticipations, Mr. Bousfield dealt in particular with the U.S.A. patent, No. 553,335 of 1896, by Crosby, in which a bar with two rollers at its extremities bearing against the carbons was moved up and down by a solenoid, so as to separate the carbons laterally, or allow them to come together under the action of springs. This device, Mr. Swinburne claimed, would, in practice, only cause the carbons to separate, and would not bring them together without causing feeding at the same time. Although Mr. Bousfield showed a model of this mechanism, Mr. Swinburne would not agree that there was a to-and-fro movement independent of the feed. Bremer's invention was, he said, the combination of an axial feed with an independent horizontal striking and adjusting motion, all effected by the same mechanism. Previous to Bremer's invention, the adjusting movement was vertical, although in some cases the striking had been performed horizontally. With regard to the alleged disconformity, Mr. Swinburne admitted that the holders for firmly gripping the electrodes and the device acting near the lower end of the carbon—namely, features (*b*) and (*d*)—were not mentioned in the provisional specification. He also agreed that a lamp depicted in Högner's specification was practically identical with that described in Bremer's complete specification.

Yesterday Mr. Walter re-examined Mr. Swinburne, and then examined Mr. Dugald Clerk, who upheld Mr. Swinburne's assertion that the specifications quoted as anticipations contained no reference to a horizontal floating adjustment independent of the feed.

ELECTRICITY SUPPLY AT CHICHESTER

Diesel Engines for Public Supply

ALTHOUGH the question of electricity supply to the town of Chichester has been under consideration more or less for a period of over ten years, it is only since the completion of the interesting little Diesel engine-driven station of the Chichester Electric Light and Power Company, which was inaugurated last Thursday week, that the town has been able to enjoy facilities for electric light and power. The original Provisional Order was acquired by the Corporation of Chichester in 1898, and held by them for some years without being exercised. In 1902 negotiations with the Corporation were entered into by a company connected with the British Electric Traction Co., and bearing the same name as the present Chichester company, but this company also failed to exercise the powers they acquired. The matter rested till 1906, when overtures were received from a new company, and arrangements were made for the old company to be relieved of their powers, which the new company took over on payment of £500. This final transfer of the powers took effect on June 27th, 1907.

The principal feature of the new station, as we have already hinted, is the use of oil engines of the Diesel pattern, and additional interest arises from the fact that the engines are the first designed and made by a British company to be put to work in a public supply station. The main considerations which led to the choice of this form of prime mover was the high price of coal in the district, a more serious factor for a station of this size than in a larger undertaking, and the extreme simplicity of the arrangement of the plant, involving neither boiler-house nor producer plant.

The station itself, of which a detailed plan and section is given in Fig. 1, consists of a single engine-room, about 40 ft. by 30 ft., situated adjoining a canal basin on the southern border of the town. The building contractor was Mr. F. J. Privett, of Portsmouth. An external view of the station is shown in Fig. 2, which gives a good idea of its compactness, considering that it is constructed to accommodate plant aggregating 450 h.p.

A view of the generating plant is shown in Fig. 3. Of the three 150 h.p. set for which provision is made, two are already in place. Each is driven by a vertical three-cylinder Diesel engine, running at 250 r.p.m., of the standard type made by Messrs. Mirrlees, Bickerton & Day, of Hazel Grove, Stockport, who acted as sub-contractors to Messrs. Johnson & Phillips, the main contractors for the equipment. These engines, although following in the main the lines of the original German design of Diesel engine (as described in ELECTRICAL ENGINEERING, Vol. I., page 559), embody one

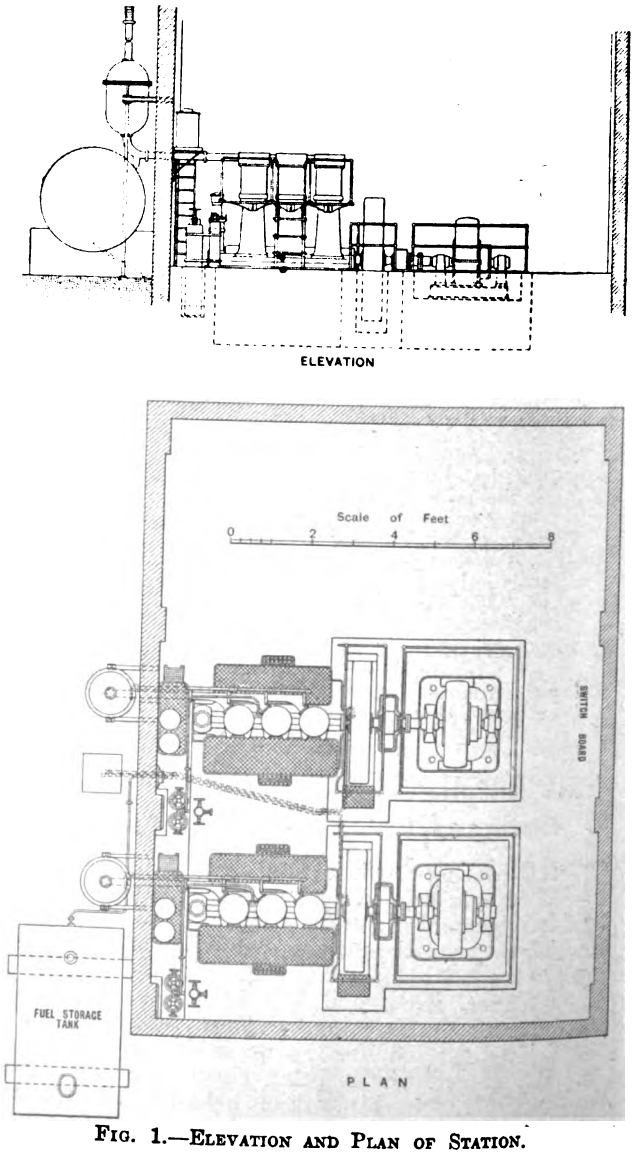

FIG. 1.—ELEVATION AND PLAN OF STATION.

or two important points of difference, which have been the outcome of Messrs. Mirrlees, Bickerton & Day's

Digitized by Google

experience. These include modifications in the arrangement of the compressors and other improvements in the method of fuel supply.

In common with the majority of makes of Diesel engine, these engines work on the four-stroke cycle, and the main point of difference from ordinary gas or oil engines lies in the character

FIG. 2.—GENERAL VIEW OF GENERATING STATION.

of the fuel combustion, which is not of an explosive character, but is steady combustion at high compression temperatures. During the compression stroke the cylinder contains air only, and the temperatures consequent upon compressing the air to about 480 lbs. per sq. in., ignite the combustible charge, dispensing with ignition tubes or sparking apparatus. The charge is blown into the combustion space by compressed air, after the maximum compression in the working cylinder has been reached. No increase of pressure occurs on the admission of the fuel, just a slow burning or combustion of the fuel in the heated air, consequently great smoothness and regularity of running is obtained. The fuel oil is blown into the cylinder by compressed air through an atomiser, and enters the cylinder in the form of a fine spray. The air required for this purpose is supplied by a two-stage air compressor, which is driven direct from the end of the engine crankshaft. The oil is delivered to the fuel admission valve by a pump driven from the camshaft; a separate pump cylinder is provided for each of the working cylinders. The quantity of oil required is determined by a specially designed knife-edge governor, mounted on the vertical shaft driving the camshaft.

The crosshead pins are lubricated by a small pump, as are the cylinder walls, but the main bearings are automatically lubricated by rings. Special attention has been paid to the accessibility of parts. All valves on the engine, including those of the air compressor and fuel pump, have separate seats, which permit of them being quickly withdrawn for examination. An important detail is the specially designed lever for operating the exhaust valve. Incidentally, the exhaust valves of all internal combustion engines require cleaning and grinding from time to time, owing to their deterioration by the passage of the hot exhaust gases over the valve faces. Messrs. Mirrlees, Bickerton & Day, Ltd., fit a split lever, and by withdrawing one small bolt the half of the lever immediately above the valve can be swung back, thus enabling the exhaust valve to be withdrawn without dismantling any of the valve operating gear. The engines are started by compressed air, which is stored in suitable receivers. By opening a stop valve the air is admitted to the piston for four or five strokes, after which the heat of compression in the cylinder is sufficient to ignite the fuel oil. By operating a lever the compressed air for starting is automatically cut off, and fuel oil is at once admitted to the cylinder. The operation of starting is so certain and simple than an engine can be started up and put on full load in two or three minutes. The storage receivers are re-charged by the two-stage air compressor previously referred to; sufficient air for ten starts is provided for.

Each engine has its own compressor mounted on the shaft, and its own set of compressed air tanks by the wall close to the engine. The two large tanks are for supplying the air for starting up, and the pressure for injecting the fuel into the cylinders at each stroke is taken from the smaller tank. The fuel supply, water-cooling, and exhaust pipes and silencers are also entirely independent. The fuel used is Texas crude oil obtained at a very cheap price. Each engine has a pair of small cylindrical tanks fixed above the level of the cylinders on the wall, and these are filled from the main ten-ton storage tank outside the building (shown in Fig. 1) by semi-rotary hand pumps. The cooling water is drawn from a spring which was discovered between the engine-house wall and the canal, and discharged into the canal. Each engine carries its own positive rotary circulating pump, and has entirely separate suction and delivery piping. An independent electrically-driven pump of similar construction is also provided, which can be used as spare to any one of the engine pumps, and is also used for filling a small overhead tank, which supplies water for auxiliary purposes.

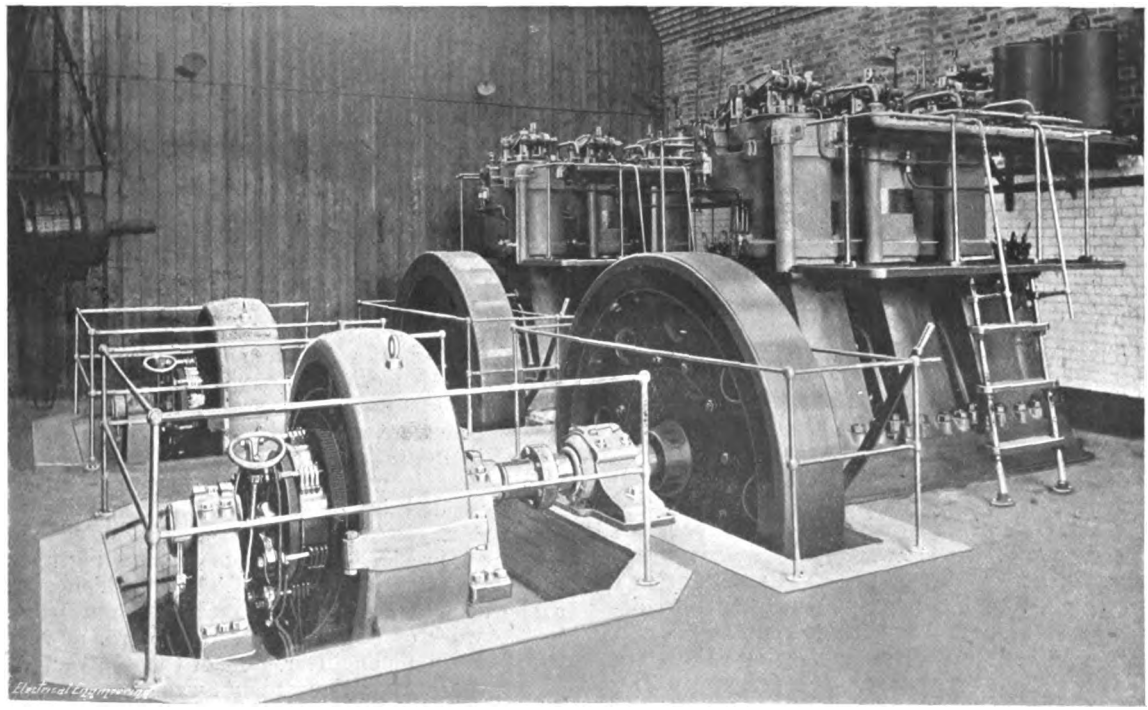

FIG. 3.—DIESEL ENGINE GENERATING SETS.

Each engine is directly coupled to a six-pole continuous-current generator, manufactured by the

Digitized by Google

General Electric Co. at their Witton works. These machines are rated at 100 kw., and are shunt wound to give 440 volts. They are fitted with interpoles, and are so designed that an over-compounding winding for 500 to 550 can be added, should they at a future time be required to run on a tramway load.

The following are the fuel consumption guarantees required for the sets:—

Full load 0·5 lbs. per b.h.p.-hour.
Three-quarter load, 0·52 lbs. per b.h.p.-hour.
Half load, 0·6 lbs. per b.h.p.-hour.
One quarter load, 0·8 lbs. per b.h.p.-hour.

Test results, however, have given somewhat better results, namely, 0·484 lbs. at full load, 0·511 lbs. at half-load, and 0·691 lbs. at one-quarter load.

The sets are required to withstand a continuous overload of 5 per cent., and momentary overloads of 25 per cent. The governing was required to permit of an adjustment of speed over a range of 5 per cent., and to prevent a rise in speed of more than 5 per cent. when full load is suddenly thrown off, or 3 per cent. when it is gradually thrown off. It was also specified that there was to be no appreciable hunting down to one-tenth load. All these requirements have been amply fulfilled on test.

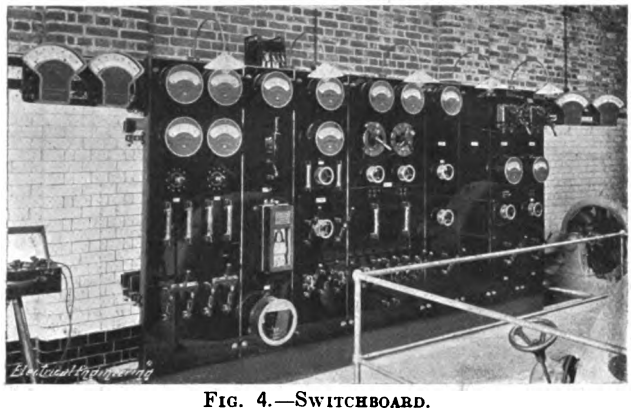

FIG. 4.—SWITCHBOARD.

The only other electrical plant is a 25-kw. balancer set manufactured by the General Electric Co., but switchgear for a battery and booster has already been provided. The engine-room is spanned by a five-ton hand travelling crane by Messrs. Herbert Morris & Bastert.

The switchboard (of which a view is shown in Fig. 4) is of Messrs. Johnson & Phillips' own manufacture, and consists of eight vertical slate panels. The three generator panels, two of which are already equipped, are at the right-hand end of the board. They are fitted with knife switches on the negative side, and circuit-breakers with maximum and reverse current releases on the positive side, and carry the generator ammeters and the hand-wheels for the shunt regulators. The main bus-bar voltmeter and a centre zero paralleling voltmeter are conveniently arranged on a hinged bracket at the end of the board, and plugs permit of the latter being connected to any generator. The feeder panel is at the left-hand end of the board, and provides for the main feeder and the distributor referred to hereafter. There is plenty of room for further feeder panels to the left; pilot wire and feeder voltmeters are carried on a bracket at the feeder end of the board. Next to the feeder panel is the middle-wire panel with recording ammeter and automatic switch, which cuts in an earthing resistance if the leakage current exceeds a certain value. A three-wire total output meter is placed on the lower part of the same panel. Following the panels from left to right, we come to the balancer panel, with starter and regulator hand-wheels, &c. A fully-equipped battery panel occupies the centre of the board, for use if required later. A booster panel to the right of the battery panel is also provided.

The principal streets of Chichester, along which mains have been laid, named North, South, East, and West Street respectively, are arranged in the form of a cross, and at their intersection is the feeding point, at which they are connected to the single feeder. Mains have also been laid in one or two adjoining streets. The distributor, following the same route as the feeder, is prolonged to the station, and can in case of necessity be used as a spare feeder, although it is normally kept unconnected at the station end. The cables were all supplied and laid by Messrs. Johnson & Phillips. The distributors are three-core cables of 0·1, 0·6, 0·1 sq. in. section, lead covered, laid direct in the ground, and covered with tarred boards. The feeder is a 0·2 sq. in. triple concentric lead-covered cable, drawn into Sykes' stoneware conduit. Under roads and railway crossings iron pipes are used for both distributors and feeders. In the main streets the distributing cables are laid entirely under the footpaths.

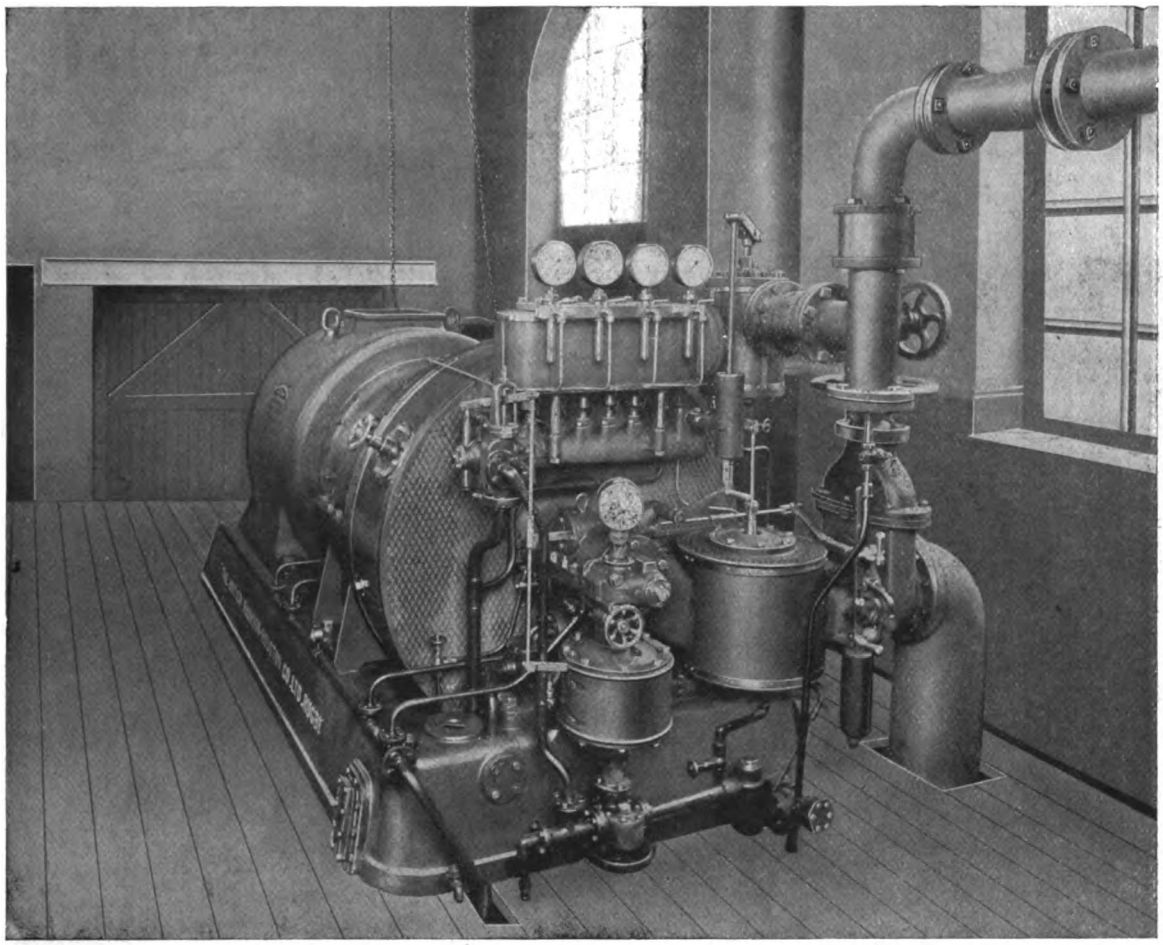
The station starts work with private lighting connections equivalent to 40 kw.

The design of the station is due to Mr. Horace Boot, who has acted as consulting engineer to the company, and to whom we are indebted for facilities for describing the undertaking. We also wish to express our thanks to Mr. R. V. Weare, the company's resident engineer, for information accorded to our representative on the occasion of a visit to Chichester, and for placing the photographs from which the illustrations in this article were prepared at our disposal.

The inauguration ceremony on Thursday, June 3rd, was undertaken by Rev. Chancellor H. M. Davey, and was preceded by a lunch at the Dolphin Hotel, at which Mr. Horace Boot (Consulting Engineer to the company) presided. Mr. Boot, in replying to the toast of "Prosperity to Electric Light in Chichester," gave a short history of the undertaking, and paid tribute to the work of both Mr. R. V. Weare, now the company's resident engineer, and of the contractors' representatives. An adjournment was then made to the works, where Chancellor Davey started the engines and the current was switched on.

CURTIS EXHAUST AND MIXED PRESSURE TURBINES

THE gain in economy which can be obtained in so many cases by the addition to existing equipments, the capacity of which it is desired to increase, of exhaust steam turbines, is being more and more widely realised, and a recent pamphlet from the British Thomson-Houston Company, of Rugby, is of interest in this connection. This firm have given a great deal of attention to the subject, and have developed designs of exhaust or mixed pressure turbines which can be used advantageously with ordinary reciprocating engines, whether condensing or non-condensing, colliery winding engines, steel works plant, and rolling mill engines, or blowing engines and air compressors. It is also possible by their aid to utilise old boilers condemned for high pressure working by firing them with waste gas to supply steam at a few pounds pressure above the atmosphere. In estimating the advantages to be gained by the combination of exhaust steam turbines with existing plant, it may be useful to remember that an exhaust turbine, supplied with steam at 1 lb. above the atmosphere and expanding down to a 28 in. vacuum, will give an output of 1 kw.-hour per 32–38 lbs. (depending on the size of turbine adopted), of exhaust steam passed through the turbine, which is equivalent to a consumption of say 22½–26 lbs. of exhaust steam per b.h.p. per hour.



In cases where the supply of exhaust steam is intermittent, as in the case of winding engines, rolling mill engines, &c., these turbines can be used in conjunction with a heat accumula-

Digitized by Google

tor, so designed as to bridge over stoppages in the steam supply of two or three minutes' duration, thus enabling the amount of live steam used to be reduced to a minimum.

The British Thomson-Houston Company manufacture at Rugby exhaust and mixed pressure turbo-generators on the well-known "Curtis" principle in sizes from 200 kw. and upwards. The "Curtis" principle particularly lends itself to this class of turbine, owing to the short shaft used, by reason of which it is claimed that these turbines occupy less floor space for a given capacity than any other make; the large clearances with maximum economy, and the substantial construction of the blading.

The "Exhaust" turbine is provided with a low pressure stage only, and is used when the turbine is required to operate principally or entirely with steam at about atmospheric pressure, but is also fitted with an auxiliary valve under the control of the governor for admitting high pressure steam, either for starting up or when the low pressure steam supply is insufficient.

750-KW. CURTIS MIXED PRESSURE TURBO-GENERATOR, AITKEN COLLIERY, KELTY, FIFE.

The "Mixed Pressure" turbine has both high and low pressure stages, similar to an ordinary high pressure turbine, but an additional inlet is provided to the low pressure stages, so that the turbine can make use of all the exhaust steam available at about atmospheric pressure, and is also arranged to utilise high pressure steam with any degree of superheat in case the supply of exhaust steam fails, or is not sufficient to drive the alternator at its rated load. The turbine is fitted with an automatic governor gear, so arranged that, when the exhaust steam supply fails or is reduced in quantity, the high pressure side of the turbine is automatically opened, and the deficiency made up by live steam from the boilers. An important feature of the B.T.H. "Curtis" mixed pressure turbines is that the high pressure steam is admitted when required to a high pressure stage, without the intervention of a reducing valve, and thus the maximum efficiency possible is obtained from such high pressure steam as may be used to practically the same degree as in an ordinary high pressure turbine. The valve gears are exceedingly simple in construction, and mechanically strong. The high pressure valves are operated by means of a series of cams mounted on a shaft, whilst the exhaust steam is admitted through a patent double-beat equilibrium valve, the whole arrangement being of the simplest character.

It may be pointed out that in the Curtis turbine the buckets are comparatively few in number, and of great mechanical strength. Indeed, we are informed that out of the Curtis sets already supplied, which aggregate over a million kilowatts, not a single instance of blade-stripping is known. The large clearances between moving and fixed buckets render them always available for service at a moment's notice, as previous warming is unnecessary, nor can damage be caused by water coming over from the boilers.

Other features of the design include a very short and rigid shaft, which eliminates troubles due to shaft deflection and vibration, and ease of inspection, obtained by the casing being divided on the horizontal centre line; so that the wheels and internal parts can be readily exposed.

The accompanying illustration shows a 750-kw. mixed pressure set installed at Aitken Colliery, Kelty, for the Fife Coal Company, and the following are particulars of a recent test made on this plant on site. The set runs at 3,000 r.p.m., and works in connection with a Körting jet condenser and a Rateau heat accumulator. The tests were principally carried out for the purpose of ascertaining the power available from the exhaust steam. It was found with a few adjustments of the various valves that the steam accumulator would take care of all the exhaust steam and deliver it to the low pressure stage of the turbine with a pressure difference of 1 lb. in the accumulator. As a vacuum on the intermittently working engines is not permissible, an automatic valve is placed in the pipe between the engines and the turbine arranged to close if the pressure in the accumulator falls below the atmospheric pressure. From the reading of instruments it was found that the load varied from 430 to 470 kw. on low pressure steam alone, exclusive of about 50 kw. which was generated and delivered to the condenser pump motors.

During the low pressure test the supply of exhaust steam was at times insufficient for the load being carried by the generator, and high pressure steam was taken in by the turbine automatically and without any hunting tendencies, the governing of the set being very steady. A load of 450 kw. was

Digitized by Google

repeatedly thrown off and on the set by opening and closing the main oil switch; the governing under these conditions being satisfactory in every respect. The vacuum registered on mercury column 28·3 in. at no load, and 27·3 in. with a load of 450 kw., the turbine using exhaust steam only.

A high pressure steam test was carried out later, the approximate full load being carried with a steam pressure of 90 lbs. and a vacuum of 27·4 in. As in the previous tests an artificial tank load was made use of so that the load could be readily adjusted to the desired conditions. The wattmeter registered an average output of 718 kw., exclusive of the motor load for the condenser pumps, which was equal to about 50 kw. The set was kept running at this load till a constant temperature was reached on the generator, the room temperature being 70° F., and the temperature in punchings and windings 105° F., showing a temperature rise of only 35° F. Full load was thrown off and on the machine, the momentary change in speed being 100 revs., or about 3½ per cent.

ELECTRIC OMNIBUSES IN BRIGHTON

THE running of electric accumulator omnibuses in Brighton will be watched by many with interest on account of the differences of opinion which have been held as to the possibility of technical and financial success with this class of vehicle, and also by reason of the methods used in the charging of the batteries at the Montague Street garage of the Brighton, Hove, and Preston United Omnibus Co., Ltd.

FIG. 1.—HALLFORD-STEVENS ELECTRIC OMNIBUSES IN SERVICE AT BRIGHTON.

The electric omnibus has many obvious advantages for public service work if the cost of battery charging and maintenance can be brought to a reasonable figure, and the advances made in this direction of late appear to open up a considerable field of usefulness for them where gradients are not excessive and a sufficient number of vehicles can be employed to secure economical methods of working. For municipalities with their own electric supply, the electric omnibus offers several attractions. The vehicles could be used as feeders to tramways, and will run in streets too narrow for tramcars. No overhead equipment or rails are required. The batteries can be charged in the night or at times of light load, thus improving the load factor of the station, and the transmission, being electrical, will be thoroughly understood by the tramways operating staff.

To omnibus companies, however, these advantages do not appeal so strongly, but signs are not wanting that the purely electric vehicle is receiving their careful consideration. This attention will naturally increase in direct ratio with the price of petrol. The whole problem of the financial success of the electric omnibus hinges on battery first cost and maintenance, and the cost of the electrical energy required for charging the batteries. The upkeep of an electric chassis is very small as compared with that of a gear-driven petrol omnibus, and within the last two years the first cost and maintenance of traction batteries has been greatly reduced, and manufacturers are attacking the weight question with gratifying results.

Before describing the charging arrangements, it may be mentioned that three of the omnibuses (see Fig. 1) are of the "Hallford-Stevens" pattern, manufactured jointly by Messrs. J. and E. Hall, Ltd., of Dartford, and Messrs. W. A. Stevens, Ltd., of Maidstone. They are very similar in general details to the "Hallford" petrol-electric omnibus, a full description of which appeared in ELECTRICAL ENGINEERING, Vol. III., page 83 (January 16th, 1908). The vehicle there described, by the way, has now run 50,000 miles in the service of Messrs. Thomas Tilling, Ltd. In the purely electric omnibus, however, a storage battery takes the place of the engine and dynamo in supplying the current to the electric motors, which are accessibly mounted on the side frames, and drive by means of cardan shafts (enclosed in steel tubes which also form torque rods), the worm gears in the S. B. & S. axle already described. The bonnet is retained, and the radiator is replaced by a light aluminium frame which carries the starting resistance. The space under the bonnet is occupied by the "Hallford-Stevens" patent interlocking controller. In this position it is very accessible, and the increased smoothness of running obtained by the longer wheel base well justifies this arrangement.

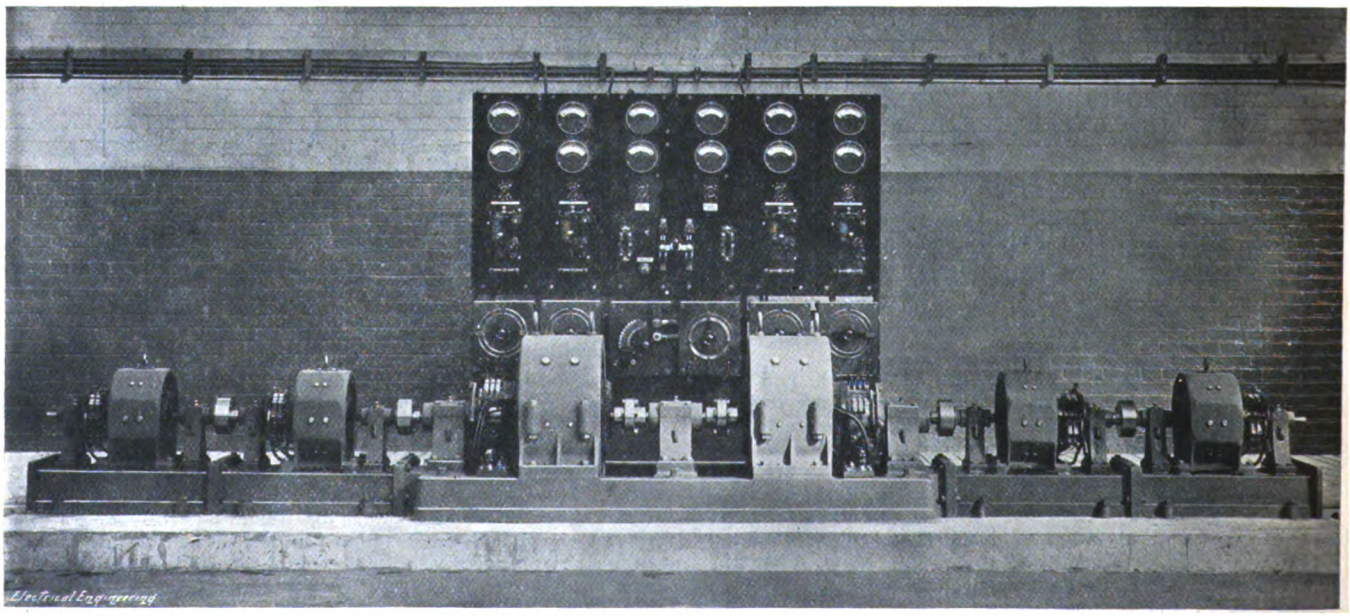


FIG. 2.—SWITCHBOARD AND BALANCER-BOOSTER SET FOR BATTERY CHARGING.

The three "Hallford-Stevens" electric vehicles shown in the accompanying photograph are in the service of the Brighton, Hove, and Preston United Omnibus Company, Limited, between Sackville Road and Castle Square. As the route includes the steep ascent of North Street (1 in 11), it will be seen that the

Digitized by Google

electric omnibuses at Brighton are working under much more arduous conditions than electric omnibuses in London. In addition to the three "Hallford-Stevens" vehicles, the company are also using a Milnes-Daimler petrol chassis converted to an electric omnibus on the Hallford-Stevens system, and three electric omnibuses by the Electric Vehicle Company, Limited. A "Hallford-Stevens" petrol-electric omnibus is also in use for the hilly route from Hove to Rottingdean.

The battery used on these electric omnibuses has 47 cells of a capacity of 500 ampere hours at the five-hour rate. The cells are arranged in the main battery box, in five lines of eight, and one line of seven cells, a vacant space being left at the end of the last row, for convenience of removing the cells from the box. The charging voltage of the batteries varies from 100 at the beginning of the charge to 130 when fully charged. A very economical method of dealing with this variation of voltage is employed, which entirely avoids the usual heavy waste in series resistances on each battery circuit, a loss in some cases amounting to as much as 12 per cent. of the total. Speaking generally, the system is to take the supply at constant voltage, and to insert in circuit with each battery the armature of a motor-driven booster of the interpolar regenerative type.

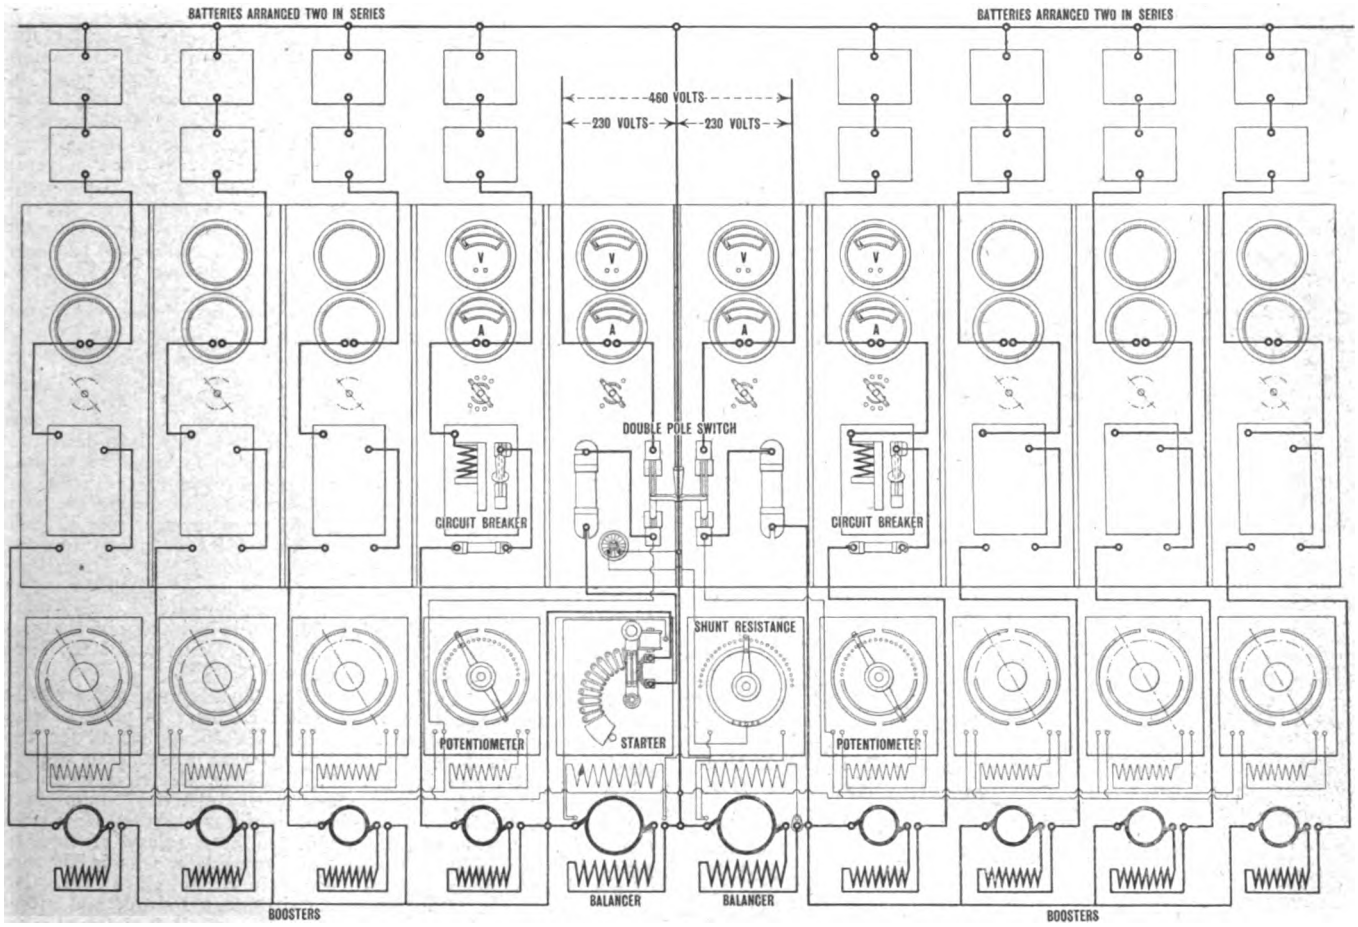

FIG. 3.—DIAGRAM OF CONNECTIONS OF BATTERY CHARGING PLANT.

By means of a potentiometer rheostat in the booster fields, the booster can be made to absorb electrical energy in the earlier stages of the charge, running as a motor and causing the erstwhile motor to which it is direct coupled to act as a generator, returning current to the line. As the voltage required by the battery rises, the resistance of the booster fields is progressively short-circuited by means of the potentiometer rheostat, until the average voltage is reached. At this point the shunt field windings of the booster are short-circuited, and the armature of the booster is inert, only serving as a conductor in series with the battery. By a further movement of the potentiometer resistance switch, the current in the shunt fields of the booster is reversed, and the voltage is gradually raised until the maximum value is reached, when the battery is fully charged; during the latter stage, the booster armature is generating electrical energy and is driven by the machine to which it is direct coupled.

At Brighton, the supply is from the public mains, and the voltage is from 220 or 230 volts on either side of the middle wire. Until quite lately the batteries were charged in series with a motor-driven booster in series with each pair of batteries. With an increase in the number of electric vehicles, however, it became necessary to build new premises at Montague Street for their exclusive accommodation, and the directors of the Omnibus Company, after consulting Mr. J. Christie, Borough Electrical Engineer to the Brighton Corporation, decided to adopt the Stevens regenerative battery charging system for the new garage, the electrical energy being supplied from the Brighton Corporation mains. Already about 7,000 to 10,000 units are being taken weekly.

As a middle wire of sufficient capacity was not available in the neighbourhood, the outers only at a pressure of 460 volts were brought to the building, and a balancer was installed to create the middle point.

A view of the switchboard and the balancer booster set is shown in Fig. 2 and a diagram of connections of the Stevens system is given in Fig. 3. It will be seen that the main supply is connected across the outer terminals of the balancers, which are direct coupled, by means of flexible couplings to a line of reversible booster armatures, four on each side, so that the system when complete will consist of ten machines running on the same axis. At the present time only two boosters are connected on each side of the balancers, but provision in the foundations is made to add additional boosters as required. The circuit from each booster is through a fuse, reverse current circuit breaker and ammeter to the terminals of a battery, the circuit being completed through the middle wire as shown. A four-way double-pole voltmeter switch is provided on each panel, so that the voltmeter can read line volts, battery volts, or booster volts, or can be connected across the circuit breaker so that the circuit can be closed when the potential difference as shown on the voltmeter (which is graduated 40 volts on one side of zero and 300 on the other) is nil.

In the earlier conditions the boosters are running as motors, but when the charging of the batteries is more fully advanced they run as dynamos—the motoring boosters pulling round the generating boosters so that the actual energy required is extremely small. The plant when completed will have a charging capacity of sixteen batteries at one time, and the total losses in conversion from 460 volts to the voltage required for individual batteries will not exceed 5 per cent. The whole of the electrical plant, including balancers, boosters, and switchboard, was manufactured and put down by Messrs. W. A. Stevens, Ltd., of Maidstone.

LOCAL NOTES

BATH: *Street Lighting.*—Competitive trials of street lighting between gas and electricity are being carried out in a number of side streets.

BIRMINGHAM: *Electricity Accounts.*—The accounts of the electricity undertaking for the year to March 31st show revenue amounting to £175,517, and expenditure £90,403. After meeting capital charges and interest on mortgages and loans, there is a balance of £10,000, which has been transferred to improvement rate, after carrying £7,000 to renewals fund. The number of units sold was 24,406,227, against 20,793,670. The average price received was 1·73d. per unit, as against 1·81d. There are now 10,716 kw. of motors connected, and the lighting consumers have an aggregate of 172,150 equivalent 8-c.p. lamps connected.

BOURNEMOUTH: *Tramway Fares.*—The revised fares upon the Corporation Tramway system are meeting with a good deal of opposition on the part of the inhabitants, and meetings of protest are being held.

COVENTRY: *Electricity Accounts.*—The annual accounts of the Coventry Corporation electricity undertaking show a net profit for the year of £3,765 5s. It is proposed to pay £1,000 to the general district fund in relief of the local rates, £2,598 to the reserve fund, to be transferred from that fund to capital account in order to meet certain capital expenses, and to obviate the necessity of raising loans, and to carry forward the balance of £167 5s. to next year's account.

CROYDON: *Electricity Accounts.*—The total receipts from the electricity undertaking for the year to March 31st, 1909, was £64,650, a decrease of £2,287 over the previous year, whilst the expenditure amounted to £34,975, an increase of £3,841. Of the increase in expenditure, however, £3,032 is of a special nature, and will have a material influence in improving the working. The actual working expenses show a satisfactory decrease, however. After meeting capital charges, there is a net profit of £6,952. The number of units sold was 6,040,551, an increase of 165,548 over the previous year. The Council have agreed to a reduction in the flat rate of charging from 4½d. to 4d. per unit, and for arc lighting from £16 to £15 per annum as from the midsummer quarter.

EXETER: *Electricity Accounts.*—The total units sold during the past year totalled 1,570,288, an increase of £62,000 over the previous year, but the expenses have not increased. In spite of reductions in tariff representing £4,000, the revenue is only £400 less than that of the preceding year. Considerable economies in coal and power-house expenses have been effected, and some minor additions to plant have been paid for out of revenue. The final surplus was over £2,000.

GLASGOW: *Tramway Accounts.*—The accounts of the Corporation Tramways Department for the year to May 31st, show income amounting to £892,751, compared with £910,318 for the previous year. The expenditure was £505,618, against £509,894. The balance, after meeting capital expenditure, is disposed of by allocating £50,000 to the common good, £195,798 to depreciation, and carrying forward £16,275.

HARROGATE: *Street Lighting.*—The Corporation contemplate the more efficient lighting of the streets by electricity.

HOYLAKE: *Electricity Accounts.*—The revenue of the electricity undertaking for the year to March 31st amounted to £8,083. After meeting all expenditure, including capital charges, there is a profit of £567.

LIMERICK: *Electric Lighting Accounts.*—It is stated that there has been a net loss on the two years' working of the Corporation's electricity undertaking of £2,092.

LONDON: *Fulham: Electricity Accounts.*—After meeting capital charges there is a balance of £3,573 upon the accounts of the Borough Council's electrical undertaking for the year to March 31st.

Islington.—The electricity account for the year ending March 31st last shows a surplus of £4,263. The receipts amounted to £52,244, of which £15,734 was for public lighting. On the other side, the cost of generation was £16,693, and on distribution £2,034. General expenses absorbed £6,084, while rents, rates, and taxes accounted for £1,830. Altogether there was £25,752 excess of income over working expenditure. The reserve fund on March 31st amounted to £18,758, while the loans outstanding on the same date were put at £415,554.

Marylebone: Management of Electricity Undertaking.—At the meeting of the Borough Council on June 17th, it was stated that Mr. A. H. Seabrook, the Council's recently appointed Electrical Engineer, had taken up his duties, and that the Electric Supply Committee had approved a scheme submitted by him for the future management of the undertaking.

Poplar: The G.B. System.—In reply to a recent suggestion by the Borough Council that the Board of Trade should institute an inquiry into the whole of the circumstances of the introduction of surface-contact traction on the Mile End Road route, the Board have stated that they have no power to institute such an inquiry.

LUTON: *Electricity Accounts.*—The gross profit upon the electricity undertaking for the year to March 31st was £6,449, and, after providing for interest and capital charges, there is a net balance of £1,958. It is recommended that £908 be transferred to relief of rates, £250 for reserve to capital expenditure on meters, and the balance to the reserve fund.

NEWPORT (MON.): *Fire at Dock Station.*—A serious fire occurred last Sunday at the generating station of the Alexandra Dock, which was practically destroyed. The docks were in darkness on Sunday night, but temporary arrangements were made for lighting on Monday. The damage is estimated at £5,000.

NORWICH: *Electricity Accounts.*—The accounts of the Electricity undertaking for the year to March 31st show a gross profit of £18,143, and after meeting capital charges the amount available is £3,700, which is an increase of £595 over the net profit for the previous year. Of this the Committee recommend that the sum of £1,200 should be transferred to the relief of rates. The total number of units sold during the year was 4,066,869, against 3,661,522 in the previous year. This is an increase of 11 per cent., compared with an increase of 29 per cent. in the previous year, and 26 per cent. in the year before.

MANCHESTER: *Electricity Accounts.*—The income from the Electricity Department for the year to March 31st amounted to £567,240, against £384,602 for the previous year. The working expenditure was £205,534, against £219,358, the gross profit being £161,706, against £165,244 for the year 1907-8. After deducting capital charges the net surplus is £12,000, against £19,543. This surplus has been handed over to the relief of rates. The renewals account has been increased during the year by £2,038 bank interest, and £21,495 from revenue account, but certain abnormal expenditure, totalling £18,848, chiefly for discarded plant has resulted in the account only showing a net increase of £4,685, the total now standing at £135,252. The reserve fund now stands at 6,358. The total capital outlay upon the undertaking is now £2,521,871. It is pointed out that reductions made in the price for light in December, 1907, have represented a concession to consumers of 16,341.

WEST HAM.—The Town Council on Tuesday night had before them the appointment of an electrical engineer in place of Mr. A. H. Seabrook, resigned. There were 36 applicants for the position, and of these the following were selected to appear before the Council: Messrs. W. J. Bache, electrical engineer, Cheltenham; H. H. Couzens, deputy city electrical engineer at Bristol; Mr. G. L. Jones, resident engineer at West Ham. In the result Mr. Couzens was appointed at a salary of £500 a year, rising to £700. The successful candidate, who is 35 years of age, had held his present position in Bristol since 1901. He was formerly generating station assistant at Bristol, and afterwards mains engineer in the same town. Before coming to Bristol he was chief assistant at the Taunton Corporation.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

ACTON.—Tenders are invited by July 12th for cables. Particulars from the Engineer.

AUSTRALIA.—The Melbourne Council invite tenders for 18 transformers. Particulars from Messrs. McIlwraith, McEacharn & Co., to whom tenders by July 7th.

BATH.—A Local Government Board inquiry was held yesterday into an application by the Corporation for sanction to borrow £11,700 for the purposes of the electrical undertaking.

BEXHILL.—A Local Government Board inquiry was held on Tuesday into an application by the Council for sanction to borrow £2,120 for the purposes of the electrical undertaking.

LONDON: *Hackney.*—Mains are to be laid at a cost of £1,156.

LLANDUDNO.—The Local Government Board has sanctioned a loan of £2,450 for plant extensions at the Electricity Works.

LUTON.—Tenders are invited for the supply and erection of a 500-kw. generator, and condensing plant.

MAIDENHEAD.—An application is to be made to the Local Government Board by the Council for sanction to borrow £400 for the purposes of the electrical undertaking.

ROTHERHAM.—The Corporation require a supply of electricity meters for the year ended July 31st, 1910. Particulars from the Electrical Engineer, and tenders to the Town Clerk by July 13th.

The Corporation also invite tenders for a supply of cable during the year ended July 31st, 1910.

SALFORD.—A Local Government Board inquiry was held last week into an application by the Corporation for sanction to borrow £2,200 for the purposes of the electricity undertaking. There was no opposition.

SOUTHAMPTON.—A Local Government Board inquiry was held on Wednesday into an application by the Council for sanction to borrow £3,600 for the purposes of the electrical undertaking.

Digitized by Google

WOLVERHAMPTON.—The Electricity Committee has authorised the expenditure of £870 on additional coal-conveying plant.

WORKSOP.—The Council invite tenders by June 29th for the supply of underground cables. Particulars from the Engineer, and tenders to the Town Clerk.

Miscellaneous

BIRMINGHAM.—The Corporation invite tenders for general and engineering stores, including electrical accessories for delivery between August 1st, 1909, and July 31st, 1910. Particulars from the City Electrical Engineer, and tenders by June 30th.

LONDON: *Greenwich.*—The Guardians invite tenders for the erection and equipment of two electric lifts at the Infirmary, Vanbrugh Hill, East Greenwich. Particulars from the Clerk, and tenders by **July 8th.**

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

N.E.—Additions to Eastern Hospital, Homerton. Architects, T. W. Aldwinckle, 20 Denman Street, London Bridge, S.E. £1,855.

N.W.—School, Torriano Avenue (£12,648). St. Pancras. Builders, J. Chessum & Sons, South Place.

W.—Depôt buildings, &c., Grove Road (£13,560), Marylebone. Builder, B. E. Nightingale, Albert Works, Albert Embankment, S.E.

W.C.—Additions at London Coliseum, St. Martin's Lane. Architects, F. Matcham & Co., 9 Warwick Court, W.C.

S.W.—Manual training centre, Park Walk, Chelsea (£1,054). Builders, S. N. Soole & Son, Sheen Road, Richmond.

PROVINCES.

ABERDEEN.—Prudential buildings (£8,000). Architect, P. Waterhouse, Staple Inn Buildings, Holborn, W.C.

APPLEBY.—Large residence (£2,200). Architect, J. Hartley, Swadford Chambers, Skipton, York.

BARNSTAPLE.—It has been decided to wire the workhouse for electric lighting.

BEDMINSTER (Bristol).—Public Hall, St. Paul's Church (£2,200). Architect, Scammell, Son & Perkin, 10 John Street, Bristol.

COVENTRY.—Additions, Coventry and Warwickshire Hospital (£3,013). Architects, A. Hessell Tiltman, 2 Verulam Buildings, Gray's Inn, London, W.C.; and H. W. Chattaway, Trinity Churchyard, Coventry. Builders, W. Moss & Sons, Ltd., Loughborough.

GREENFIELD, HOLYWELL.—School (£3,000). Architect, S. Evans, County Offices, King Street, Mold.

GOSPORT.—Baptist Church (£2,215). Architects, John Wills & Sons, Victoria Chambers, Derby. Builder, J. Hunt, South Wharf, Gosport.

GLASGOW.—New factory for the Scottish Co-operative Society (£4,300). Architect, J. Davidson, 95 Morrison Street, Glasgow.

HOUNSLOW.—Hospital. Architects, Messrs. Franck & Wheeler, c/o the Secretary, Hounslow Hospital Committee.

HERNE BAY.—New Pavilion on Pier. Boro' Engineer, Town Hall, Herne Bay.

NEWBIGGIN.—School (£3,000). Architect, J. Forrest, Moot Hall, Newcastle-on-Tyne.

NEWARK.—Girls' High School. Architects, Brewill & Bailey, 44 Parliament Street, Nottingham.

NEWBRIDGE.—Thirteen villas (£263 each). Architects, A. J. Bowen, Crumlin, Mon. Builders, A. S. Morgan & Co., Newport.

NORTHAMPTON.—Sanatorium. Architect, F. Dorman, Market Square, Northampton. Builder, J. T. Bowell, Larne Road, Northampton.

OXSHOTT.—Large house (£2,000). Architect, A. S. Taylor, 27 Old Queen Street, S.W.

PORTSMOUTH.—Swimming Bath, North End. J. Murch, Borough Engineer, Town Hall, Portsmouth.

SOUTH SHIELDS.—120 houses (£25,000). Architect, F. H. Grieves, 63 King Street, South Shields.

STOURMINSTER (Newton).—County School (£1,200). W. J. Fletcher, County Surveyor, Wimborne.

SHERBORNE (Dorset).—Digby Memorial Hall (£2,200). Architect, C. & C. B. Benson, 11 Hendford, Yeovil. Builder, Guppy & Son, Sherborne.

SWANSEA.—Tenders are to be invited for the installation of electric light at the Technical College.

WALLASEY.—Secondary School (£15,000).— Architect, H. Beswick, Newgate Street, Chester. Builder, T. G. Huxley, Malpas.

WHITEHAVEN.—Laundry. Architect, J. Ramsey, Market Place, Whitehaven.

TENDERS RECEIVED AND ACCEPTED

ABERTILLERY.—The Council have accepted the tender of Messrs. Johnson & Phillips, Ltd., for the supply and erection of an overhead transmission line and underground mains.

BERWICK.—The Urban Electric Supply have placed an order with Mesrs. Johnson & Phillips, Ltd., for the supply of 16 of their long-burning magazine flame arc lamps.

BRIDGEND.—The Bryndu Colliery Co. have accepted the tender of Messrs. Johnson & Phillips, Ltd., for the supply and erection of vulcanised bitumen surface and shaft cables, distribution boards, &c.

EBBW VALE.—The Ebbw Vale Steel, Iron & Coal Co. have placed an order with Messrs. Johnson & Phillips, Ltd., for the supply and erection of a 6,600-volt 3-phase overhead transmission line.

GLASGOW.—The Electricity Committee recommend the acceptance of the following tenders: 1,000-kw. motor-generator, Messrs. Bruce, Peebles & Co., £2,280; a 500-kw 500-volt rotary convertor, The British Westinghouse Co.; a 250-kw. 500-volt rotary convertor and a 250-kw. 210-volt rotary convertor, The British Thomson-Houston Co., £1,568 and £1,632 respectively; fans for cooling-towers at St. Andrew's Cross Power Station, Messrs. Matthews & Yates, £1,049.

GRAVESEND.—The Electricity Committee recommend the tender of Messrs. Johnson & Phillips, Ltd., for the supply and erection of long-burning magazine flame arc lamps, posts, &c.

LEITH.—The Electricity Department have placed an order with Messrs. Johnson & Phillips, Ltd., for the supply of 40 arc lamps, "Bell" contact gears, and accessories.

LINCOLN.—The Waterworks Committee have accepted the tender of Messrs. Johnson & Phillips, Ltd., for the supply and erection of telephone line, instruments, &c.

LONDON: *Kensington.*—The Borough Council has accepted a tender of Messrs. Crompton & Co., Ltd., at £256, for lowering contact gear, for a further 50 arc lamps.

London County Council.—The tender of Messrs. B. & S. Massey for an electrically-driven hammer at the central car repair depôt at £273 is recommended for acceptance, and that of Messrs. J. Holroyd, Ltd., at £108, for the supply of milling cutters.

The tender of Messrs. Hadfield's Steel Foundry, Ltd., for the supply of manganese points at £32 per pair, is recommended for acceptance. The only other tenderer, namely, Messrs. Edgar Allen & Co., Ltd., quoted £34 per pair.

Hammersmith.—The Borough Council has accepted the following tenders in connection with the electricity undertaking: W. Geipel & Co., carbons, £284 12s. 5d.; Aiton & Co., exhaust steam and water pipes, £95; Gwynne's, Ltd., centrifugal pressure pump with motor (250,000 gallons per hour), £470.

Hornsey.—The Corporation have accepted the tender of the British Thomson-Houston Co., Ltd., for the supply of mercury meters for twelve months.

London County Council.—The following tenders have been received for the electric wiring of a new secondary school at West Hill, Wandsworth:—S. R. Love & Sons, £655; Pinching & Walton (*accepted*), £665 3s.; R. Bridger & Co., £694 9s.; C. Larkins & Co., £719 14s.; G. Weston & Sons, £720; Tilley Bros., £722 12s.; Balchin Schulz & Co., £740; R. J. Mecredy, Eaton and Davidson, £740; S. Newton & Co., £750; Harper Electric Co., £762 9s.; G. Harland, Bowden & Co., £771; G. E. Taylor & Co., £789; D. J. MacDonald, £796 10s.; Casperds, £824 10s.; Whitehead Bros., £848 9s.; G. Foster-Curtis & Co., £876 14s. 9d.

The tender of Messrs. Grant & Blake has been accepted for the electric wiring of the enlargement of the Oliver Goldsmith's School, Peckham.

The following tenders have been received by the Highways Committee in connection with the construction of 200 new electric cars of standard pattern. Tender A is the price per car body for car bodies fitted with side life guards and lifting steps as at present fitted to the Council's cars, and including a provisional sum of £15 per car for extra works. Tender B is the price per car body for bodies fitted with life guards and lifting steps of the "Simplex" type, and including a provisional sum of £15 per car for extra works. Messrs. Hurst, Nelson & Co. (*a*) £390, (*b*) £386 15s.; The United Electric Car Co., Ltd. (*a*) £400, (*b*) £400; Brush Electrical Engineering Co., Ltd. (*a*) £412, (*b*) £412 10s.; Metropolitan Amalgamated Railway Carriage & Wagon Co., Ltd. (*a*) £412, (*b*) £413 10s.; Gloucester Railway Carriage & Wagon Co., Ltd. (*a*) £419, (*b*) £425 12s.

Tender A, by Messrs. Hurst, Nelson & Co., Ltd., is recommended for acceptance.

The following tenders have been received for trucks for the above 200 cars. The price including £5 per pair of trucks for extra works:—Hurst, Nelson & Co., £23,900; Mountain & Gibson, £26,550; Heenan & Froude, £26,950; W. R. Renshaw & Co., £27,500; United Electric Car Co., £28,000; Metropolitan Amalgamated Railway Carriage & Wagon Co., £30,000; Brush Electrical Engineering Co., £31,000; The Peckham Development Co., £33,000. The tender of Messrs, Hurst, Nelson & Co. is recommended for acceptance.

For the supply of electrical equipments for the cars the following tenders were received, the price including a provisional sum for trolley equipment, and £24 10s. for extra works and

Digitized by Google

supply of ploughs:—British Westinghouse Electric & Manufacturing Co., £63,650; Dick, Kerr & Co., £65,000; British Thomson-Houston Co., £66,750. The tender of the Westinghouse Co. is recommended for acceptance.

The following tenders have been received for converting a 2½ ton single motor overhead crane at the Central Car Repair Depôt into a three-motor type crane:—Messrs. Applebys, Ltd. (*recommended*), £374; Royce, Ltd., £415; Messrs. Higginbottom & Mannock, Ltd., £460 5s.

Westminster.—The City Council has accepted the tender of Messrs. Belshaw & Co. at £42 15s. for two arc lamps at the swimming bath, Buckingham Palace Road.

PARTICK.—The Burgh of Partick have placed an order with the Lancashire Dynamo & Motor Co. (Trafford Park, Manchester) for one 1,000-kw. Bellis-L.D.M. set complete with condenser cooling-tower and pipework.

STOKE-ON-TRENT.—The Midland Coal, Coke, & Iron Co. have placed an order with Messrs. Johnson & Phillips, Ltd., for the supply and erection of single- and three-cored vulcanised bitumen cables for their Birley Pit.

SWINTON AND PENDLEBURY.—The tender of Messrs. Callender's Cable & Construction Co. has been accepted for the supply of cable, service boxes, &c., at £121.

WHITEHAVEN.—The Corporation have accepted the tender of the Phœnix Dynamo Co. for a balancer.

COMPANIES' MEETINGS AND REPORTS

R. WAYGOOD & CO.—The annual general meeting was held on Thursday, when the report and accounts were adopted. The gross profit for the year 1908 amounted to £23,586, against £23,448 in 1907. To this has to be added transfer fees and the sum of £3,544 brought forward from the previous year, making a total of £27,159. After meeting directors' fees and preference dividends, writing down patents to the extent of £500, and adding £1,500 to reserve fund, it is proposed to write down investments by £3,000, which leaves a balance of £11,259. An interim dividend of 5 per cent. has already been paid upon the ordinary shares, and the directors now propose a further dividend of 6 per cent. per annum for the second half of the year, making 6 per cent. for the year. A balance of £3,159 is then carried forward. In view of the increasing competition in lift working, the directors have acquired what they believe to be valuable patents in connection with heavy crane work, which are applicable to both electric and hydraulic cranes.

MARCONI'S WIRELESS TELEGRAPH CO.—The report for the period of 15 months ended December 31st, 1908, states that of the 250,000 7 per cent. preference shares of £1 each recently offered, the public subscribed 125,080 preference shares. Although this amount was short of the sum necessary to carry out the entire programme outlined in the prospectus, it was, nevertheless, sufficient to meet the company's current engagements and to provide for the expenditure required to complete the transatlantic stations at Clifden and Glace Bay, and, in addition, allowed the carrying out of a scheme of reorganisation of the works. The close attention of the directors has been given to the completion of the transatlantic stations at Clifden (Ireland) and Glace Bay (Canada). The Clifden station is actually complete. The directors regret that at present they are not able to declare the payment of a dividend. The remunerative business is extending in every direction, however, and the dividend-paying period will, it is confidently anticipated, speedily be entered upon. The meeting is on the 28th inst.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £60 to £60 10s. (last week, £61 10s. to £62).

ESCHER, WYSS & CO.—We are informed that the arrangement between Messrs. Escher, Wyss & Co. and Mr. Jens Orten Böving, who formerly represented them in this country, terminated on May 1st last, and that all inquiries intended for the firm should be addressed to their new London office at 109 Victoria Street, Westminster (Telephone: Victoria, 1454). The company's principal specialities include water turbines, Zoelly patent steam turbines, high- and low-pressure centrifugal pumps, die making machinery, paper making machinery, river boats, launches, and air compressors.

CHANGE OF ADDRESS.—The address of Messrs. Kincaid, Waller, Manville & Dawson will in future be St. Stephen's House, Victoria Embankment, Westminster. St. Stephen's House adjoins the Embankment entrance of the Westminster Bridge station on the Metropolitan District Railway. The firm's telegraphic address and telephone numbers remain as before.

SHIP CARBONS, LTD.—This firm inform us that Mr. Paul Weiss, Secretary, and Mr. Franz Taussig, Manager, have ceased to be in their employment. They have provisionally appointed Mr. A. Pavlovits as Secretary and Manager, and he is at present the firm's sole recognised representative.

APPOINTMENTS AND PERSONAL NOTES

Mr. J. M. Calder has been presented with a silver tea service by the staff of the Reading Corporation Tramways, on the occasion of his marriage.

The salary of Mr. C. S. Taylor, mains superintendent at Watford, has been increased from £95 to £110, rising to a maximum of £130 by annual increments of £10; Mr. G. A. Ayre, shift engineer, has been placed on the same scale as the other two engineers, viz., £90, rising to £105 by annual increments of £5.

Islington Borough Council has appointed Mr. A. E. Faver constructional and repairs engineer to the Lighting Department at a salary of £3 per week vice Mr. M. H. Adams resigned. Mr. Alfred Jarratt, testing assistant, and who has been in the service of the Council for three years, has been promoted to fill the vacancy caused by the resignation of Mr. J. J. Hargreaves, mains engineer.

Hackney Borough Council has granted an increase of £10 a year to Mr. C. Lill, sales engineer of the Electricity Department.

PARLIAMENTARY INTELLIGENCE

LIVERPOOL CORPORATION BILL.—This Bill, which seeks to authorise the construction of a number of new tramways by the Liverpool Corporation, was passed by a Select Committee of the House of Commons last week. The estimated capital expenditure upon the new lines is £130,000, for which the necessary borrowing powers are asked for in the Bill. The period for completion of works is five years, and the loans have to be repaid in thirty years in respect of tramways, and fifty years in respect of the necessary land for street widenings. Opposition was offered to a route to Huyton by the London and North-Western Railway, on the ground of competition with an existing railway. The railway company called Mr. J. R. Salter, the General Manager of the Lancashire United Tramways Co., who expressed the opinion that the proposed line could not pay, and similar evidence was given by Mr. Stephen Sellon, who claimed that the capital expenditure upon the line, namely, £60,000, was too low. He put the figure at £71,000. The Committee, however, passed the preamble of the Bill with this line included.

Wireless Telegraphy.—The arrangements for the erection of an Admiralty wireless station on the high ground of Sastland Hill overlooking Rosyth naval base, have been completed. It is expected that the station will be complete and ready for use in 12 months' time.

According to the *Board of Trade Journal*, it is reported that the Pacific Islands Radio-Telegraphy Co., recently incorporated in London with a capital of £60,000, will soon commence operations, and that a French company has been formed for the establishment of a station at Tahiti.

A man named Michael Cooney, an electrician at the Admiralty wireless station at Humberstone, near Grimsby, died on Saturday from burns and shock received when at work in the station. It appears that he inadvertently took hold of a high-tension wire. At the inquest, held on Monday, the jury returned a verdict of accidental death, and exonerated the staff from any blame.

Cable Explosion in London.—A slight explosion occurred in Piccadilly Circus on Friday afternoon due to a short-circuit on one of the feeders of the distributing network of the St. James's & Pall Mall Electric Light Co., Ltd. The lid of an inspection box in the pavement was blown out, and some material in the box caught fire, but the flames were soon extinguished. Fortunately, no one sustained any injury.

Telegraph Traffic.—The cables notified in our previous issue as being broken remain so. The land line between Bagdad and Bassorah was again in trouble on the 16th inst., but repairs were effected on the same day. Communication between Rome and Constantinople was restored on the 16th inst., while an interruption again occurred on the 18th inst. The submarine cable between Tourane and Amoy failed on June 17th, and on the 18th inst. it was only possible to send telegrams to Recht and other places in Ghilan "via Teheran," at the risk of the sender, by reason of frequent interruptions to the direct line between Recht and Teheran. The Commonwealth of Australia has since the 1st ult. laid two cables between Victoria and Tasmania, and will work them themselves. This cuts out the Eastern Extension, Australasia and China Telegraph Co., who owned the cables formerly serving as a link between these two places. Owing to a dispute between the company and the Government on the question of rates, the latter has not renewed the Eastern concession. It is believed the company will pick its cables up. Censorship has been established in Paraguay, and martial law has been proclaimed. Communication between Rome and Constantinople has been restored. The cable of the West India & Panama Telegraph Co., failed on the 19th inst.

FOURTEENTH ANNUAL CONVENTION OF THE INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION

UNDER the Presidency of Mr. S. L. Pearce, City Electrical Engineer, Manchester, the fourteenth annual Convention of the Incorporated Municipal Electrical Association was opened at the Manchester Municipal School of Technology on Tuesday. On the previous evening the Lord Mayor of Manchester (Alderman Edward Holt, J.P.) gave a reception and conversazione in the Town Hall, at which about 700 persons were present.

On Tuesday morning The Rt. Hon. the LORD MAYOR, in welcoming the Association to Manchester, said there were many factors in connection with electricity which required investigation, and one of the most important was whether a manufacturing department of a corporation should sell to the customers at cost price, or whether a reasonable profit should be made. He was a believer in the latter proposition, as he did not consider that the ratepayer should find the capital without sufficient remuneration. He knew that his own Electricity Committee did not agree with him, however. Another very serious question was that of competition between the various municipal departments. At Manchester, for instance, they had departments in connection with hydraulics and electricity, and a line must be drawn as to where the competition between them should cease. They must also not forget that municipal undertakings, like all others, were subject to trade depression, and, consequently, they must be very careful to allow, in times of prosperity, sufficient for depreciation and reserve funds to provide for times of depression. In conclusion, he expressed his pleasure at the election of Mr. Pearce as President of the Association.

MR. PEARCE, having thanked the Lord Mayor for his welcome, delivered his Presidential Address:—

PRESIDENTIAL ADDRESS

BY S. L. PEARCE

(City Electrical Engineer, Manchester).

MR. PEARCE first expressed sincere appreciation of the honour conferred upon him in selecting him as President, and alluded to the fact that, contrary to the custom of most institutions, the Presidential Address to the I.M.E.A. is made when the President's year of office is about to terminate.

The President then proceeded to review a number of matters to which particular attention is being directed at present by members of the Association. The first of these was the necessity of providing adequate reserves for renewals of plant, in so far as these cannot be met by further borrowings.

It is now generally accepted, he said, that in so far as the Statutory Sinking Fund instalments unaided will not provide for the redemption of the loans for short-lived assets, by the end of the term fixed by the sanctioning authority, some additional charge against revenue is necessary, to provide for either the repayment of the balance of the loan then outstanding, or a corresponding part of the cost of the renewal of these assets. It is desirable that this supplementary charge on revenue should be annually apportioned. The fund thus accumulated then also serves to equalise the charge against the yearly revenue accounts, and relieves the latter from the fluctuations that would otherwise normally occur.

Too often it is feared moneys are taken in relief of the rates which should have been applied in provision for renewals or depreciation. Strictly speaking, depreciation being an operative expense, ought to be charged against revenue before profits can be ascertained. Once so charged, carried to a separate account, and a corresponding cash transfer made, revenue has no further concern with either depreciation or sinking fund for repayment of debt. It is then competent as a matter of finance to utilise the Depreciation Fund mainly in meeting the Statutory Sinking Fund charges, and to a lesser degree in financing renewals to the extent to which *re*-borrowing powers are unobtainable.

The question of a reserve to meet any general contingencies that may arise, or to provide for an "antiquation" fund, is more difficult to determine, but should, if at all possible, be provided for. The standard set may be high, but it is worth aiming for.

Having given due consideration to this aspect of financial policy, it is at least arguable as to whether the object of all municipal undertakings should not be to supply current at or near, cost price, and not to relieve the rates out of profits to benefit non-consumers. The former course would ultimately be of benefit to the municipality in inducing the founding of new businesses with the consequent addition to the rateable value of the city. The policy advocated by the extreme municipalists in acquiring trading undertakings free from debt (within the life of the first equipment) instead of trading with borrowed capital, is one not likely to meet with the approval of this Association. It is, however, obvious that if the Legislature were to impose the obligation on municipalities of providing full and proper depreciation, and in addition, an extra sinking fund of ½ per cent. per annum, thus entirely freeing trading undertakings from debt in sixty-nine years, the increase in current expenses would be imperceptible. Unfortunately the tendency at the present time in view of ever increasing rates is to look to the trading departments for more and yet more relief in the shape of increased contributions. So far as lies in our power this tendency should be resisted as being detrimental to the best interests of trading concerns.

Dealing next with the advent of the metal filament lamp, and the consequent serious reductions in output and diminished revenue, Mr. Pearce pointed out that this is only a temporary check to the progress of supply undertakings, and that, as consumers recognise that a substantial increase in candle power can be obtained with a corresponding decrease in energy consumption, there will be an inevitable reaction to the present "slump" in output.

It is, he continued, only natural that various proposals should have been made to devise a tariff which shall meet the altered conditions of supply, but his view is that a raising of prices is to be deprecated. He inclines to the view that the worst of the check has been experienced. Still higher efficiency lamps for low voltages may be put on the market, but against this, the high voltage lamp of moderate candle power is likely to be more widely used, which must have a tendency to keep the consumption steady whilst giving increased illumination. Further, he thinks there will be a demand for a lamp in which some of the efficiency is sacrificed for stability. Nothing should be done to arrest an increase in new connections. In the case of those authorities supplying a mixed load, he pointed out that the small percentage of the plant liberated is available for power demands, so that the resultant effect on the station must be some increase in the load factor and on the system as a whole a probable increase in the diversity factor.

On the subject of "Cheap Wiring," Mr. Pearce emphasised the point that it does not follow that because an installation may be a cheap one, it is necessarily defective, or fundamentally bad, and he expressed the hope that the cable manufacturers will give their serious attention towards producing a class of flexible that will meet the conditions of service required in this country.

The present costs of wiring with casing or tubing, he said, do certainly preclude the obtaining of the business of the small consumer, and in his opinion, a system involving the use of "flexibles" above a given height from the ground, excepting where wires pass through walls, floors, or ceilings, need not involve lowering the standard of safety. Some economies could be further made in increasing the limit for the number of lamps to be wired on a two-wire service, by the use of two-wire circuits wherever possible in houses instead of three-wire circuits, and by increasing the allowable number of lamps per circuit.

On the question of tariffs for power, Mr. Pearce could speak particularly with authority, as in Manchester something approaching 1,000,000 h.p. is utilised.

The argument of the critics, he said, is that many of the power tariffs are unremunerative, and whilst the present deficit on power sales is masked by a big surplus on lighting sales on account of the greatly preponderating output for the latter, the time will speedily come when the power load is big enough to make the deficit larger than the surplus. Mr. Pearce does not accept this view. He believes that the majority of power tariffs framed are remunerative, although in certain cases they may have involved some remission in the fixed charges to large power users. On a system in which plant is now being put down to deal chiefly with power supplies, the installation of this more modern plant, and utilising larger units, will, on present day prices, only cost one-half to one-third of the price per kw. of the plant forming the existing installation, erected, say, seven years ago. In such a case, he thinks it would most certainly be equitable to remit a proportion of the fixed charges

Digitized by Google

on capital in the case of those consumers, whilst debiting them with their full share of the remaining standing costs.

Referring to the complaint frequently made that supply to tramways is charged at a higher rate than to other power users, Mr. Pearce suggested that if the matter were carefully investigated, it would be found that in each case the load factor on the power supply was substantially greater than it was for traction supplies. On the Manchester system, the traction load factor is 32 per cent., and the *average* power load factor, 51 per cent. Again, traction plant and traction mains are not common in the sense that the same plant and mains can be used equally for lighting and power.

A portion of the address comments on the "disposition in certain quarters to force local authorities to disclose the nature and terms of special supplies on the ground of preferential treatment."

Whilst believing that publicity is good, and that supply authorities cannot be too ready to give information in regard to their undertakings, which will lead to mutual confidence between the ratepayers and themselves, Mr. Pearce regretted that such an unbusinesslike method of proceeding as the above should be forced upon them.

After alluding to the Electric Lighting Acts Amendment Bill, the opposition to the North British Electric Power Syndicate, Ltd. (who, without any Parliamentary powers, or Provisional Order, and working under no Electric Lighting Acts, are seeking, by virtue of an arrangement with two of the Scotch Railway Companies, to give a supply within the area of a municipal authorised undertaking), and the success of the recent Manchester Electrical Exhibition, the Address next referred to the question of mutual assistance between existing supply authorities, as exemplified by the Bills that were before Parliament last session in connection with London's electricity supply :

I venture to think that the problem of supply from the stations of small local authorities has been materially altered during the past few years, and if economical and sound progress is to be made, it will in many cases prove to be along the lines of purchasing bulk supplies at low rates from neighbouring municipalities, or, failing them, from power companies. The Legislature should, therefore, speedily provide for combination amongst municipal authorities along the lines suggested in the Amendment Bill to the Electric Lighting Acts now before Parliament.

The last subject dealt with was the *status* of the municipal electrical engineer :—

There are not wanting signs to-day that there was never a time when it was more necessary for the municipal engineer to uphold his position in connection with electrical undertakings. There seems to be a disposition abroad to depose him from the position of the controlling force, that whilst his technical abilities are not called into question, he is supposed to be lacking in sufficient commercial knowledge, or business acumen, to enable him to successfully pilot the concern for which he is responsible. Pushfulness he may lack, but it cannot be said that an engineer worthy of the name lacks commercial knowledge and aptitude, and as in the administration of electricity departments, science and technical knowledge enter in at every point, and largely determine all questions of high policy, the engineer must be referred to in the end as the controlling officer acting under, and subject to, the Municipal Committee.

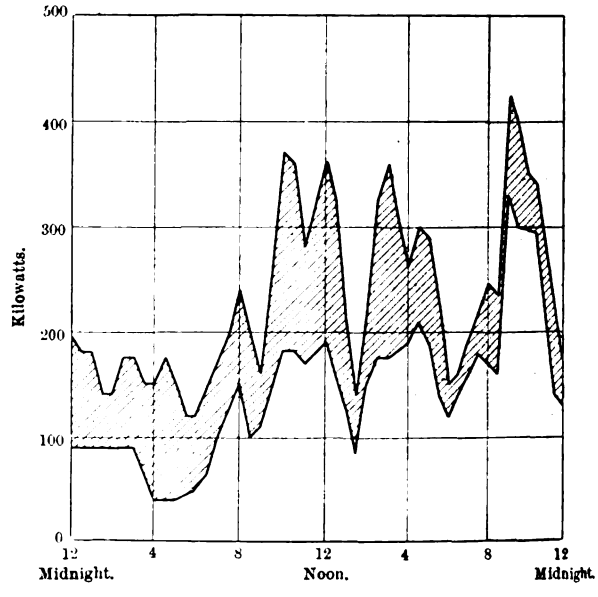
BAILIE WILLOCK (Glasgow), in proposing a vote of thanks to the President for his address, referred to the question raised of handing over profits from the electricity undertaking to the relief of rates. The Corporation of Glasgow never did such a thing until due consideration had been given to the question of depreciation, and each trading Committee must act independently in this respect. In Scotland municipalities were particularly thankful for the assistance given by the Association with regard to the North British Electric Power Co. mentioned in Mr. Pearce's address.

COUNCILLOR SINCLAIR, Chairman of the Swansea Electricity Committee, then read his Paper on "Cheap Units," which we give in a condensed form below :—

CHEAP UNITS.

BY COUNCILLOR ALEX. SINCLAIR

(Chairman of the Electric Lighting and Tramways Committee, Swansea).



The author's attention was recently drawn to the effect produced on a supply undertaking by several large consumers temporarily ceasing to take their ordinary supply on a day in June. Reference to the diagram below shows the daily output under otherwise similar conditions with and without the large users' load, the shaded portion representing the supply to the large power users. On investigating the actual works costs per unit generated under the two conditions, it was found that the units shown by the shaded portion of the curve were generated very cheaply. The advantage to the station of a power supply is apparent by the number of units generated in both instances, viz., 5,705 and 3,524 respectively, leaving 2,181, which without the large power user would be lost to the undertaking. The load factors for the day in question (*i.e.*, the ratio between the average and maximum load during the day) were 55·9 per cent. and 44·5 per cent. respectively.

A further advantage is clearly set out by dividing the units into four equal parts of the day, thus :—

Time.	With.	Without.	Large Power.
12 to 6 a.m.	937	406	531
6 ,, 12 noon	1,475	825	650
12 ,, 6 p.m.	1,625	981	644
6 ,, 12 midnight	1,668	1,312	356

So that, with the exception of meal-times, the machinery in use is for three-fourths of the twenty-four hours running at a high efficiency. In the author's opinion the 25 per cent. overload capacity of the plant should be treated entirely as being there for emergency purposes only, and the plant capacity required to meet the demand on peak load should be the measure taken for allocating the capital charges to a power user of large amount.

During the periods dealt with, the units for large power were generated for less than ¼d. per unit, exclusive of capital charges, and on an assumption that the ordinary units for lighting, &c., remained the same whether large power users were on or off. The author is of opinion that such units as these under consideration should in no way be looked upon

as by-products, but that they should each bear a fair proportion of the costs incidental to the generation of the whole; for this purpose he has taken as an illustration a typical station having an annual turnover of 2,000,000 units, and by splitting up the costs for the various supplies he arrives at the fair cost per unit for each. The divisions taken are :—

A.—Early closing shops and offices.
B.—Late closing shops and offices, private houses, theatres, hotels, &c.
C.—Small users of power.
D.—Public lighting, and
E.—Large users of power.

In the early 'nineties Colonel Crompton, the writer thinks, showed a somewhat novel way of depicting the ideal cost per unit by taking the best result for each division of cost from the then published electricity supply accounts. Following this example, the ideal figures would now be :—

Coal	0·20d.
Oil waste, &c.	0·01d.
Wages	0·06d.
Repairs	0·04d.
Works cost	0·31d.
Rent, rates, &c.	0·02d.
Management	0·03d.
Total costs	0·36d. per unit.

This may seem Utopian, but the figures of the Stalybridge undertaking have shown that it can be done for 0·45d. It cannot, therefore, be considered as being beyond the possibilities of the near future. It is not, however, the intention of the writer to deal with such very low costs, but to take, as a fair present day practice, an average of 1·11d. per unit as total costs on a 20 per cent. load factor for a station having an output of, say, two million units per annum. Taking this as

Digitized by Google

a basis, the author has compiled the table given in abbreviated form below, which gives what he considers would be the costs of supply at various load factors from this hypothetical works.

The author uses this table to work out the costs that should be allowed in the case of the five classes of consumers mentioned.

Total Costs and Capital Charges per unit for different load factors. The Capital Charges are calculated at 7 per cent. on £120 expenditure per kilowatt maximum demand.

Load Factor. Per Cent.	Total Costs (pence).	Capital Charges (pence).	Load Factor. Per Cent.	Total Costs (pence).	Capital Charges. (pence).
10	2·10	2·30	36	0·698	0 639
12	1·80	1·917	38	0·662	0·605
14	1·565	1·643	40	0·630	0·575
16	1·37	1·438	42	0·598	0·548
18	1·22	1·278	44	0·566	0·523
20	1·11	1·150	46	0·538	0·500
22	1·03	1·045	48	0·516	0·479
24	0·97	0·958	50	0·500	0·460
26	0·912	0·885	52	0·486	0·442
28	0·863	0·821	54	0·475	0·426
30	0·818	0·766	56	0·465	0·411
32	0·775	0·719	58	0·456	0·397
34	0·735	0·676	60	0·450	0·383

In Class A—early shops, &c.—it is found, subject to above remarks, that the year's consumption is 330,000 units, with a maximum demand of 358 kilowatts.

In Class B—late closing shops, &c.—there are 464,000 units on a maximum demand of 396 kilowatts.

In Class C—small users of power, &c.—400,000 units for 160 kilowatts maximum.

In Class D—public lighting—226,000 units for a maximum demand of 56 kilowatts.

In Class E—large users—580,000 units for 130 kilowatts maximum.

From the table, the writer has allocated the costs to these demands as under:—

	Units.	Load Factor.	Cost per Unit.		Total Cost.
A	330,000	10·5%	2·02d.	=	£2,778
B	464,000	13·38%	1·64d.	=	3,171
C	400,000	28·50%	0·85d.	=	1,416
D	226,000	46·00%	0·54d.	=	508
E	580,000	50·90%	0·49d.	=	1,184
					£9,057
	2,000,000	20·75%	1·08d.	=	£9,000

The author next deals with the allocation of the capital charges. First, where a large power consumer is cut off during peak load, thus preventing him from overlapping with the bulk of the other consumers, the capital charges on the maximum demand of the station do not come into the problem of his supply. If he is on cables already laid, he should bear his share of the capital costs on them, or if new cables had to be laid some distance to meet his requirements, the value of such cables should be the determining factor in allocating his share of the capital charges, and bearing in mind that he may at some date cease to take supply, a sufficiently high rate of interest should be charged to this amount to meet such risk. Taking a hypothetical case of a customer requiring 400,000 units per annum, with L.F. of 50 per cent.; to afford him a supply, an expenditure of, say, £3,000 is necessary for cables. Taking 12 per cent. as sufficient to cover interest and the risk already referred to, it would follow that a sum of 0·108d. per unit would be necessary to cover this outlay, which, added to 0·5d. from the Costs column in the table, would make the cost per unit 0·608d.

For other cases, the author has prepared the "Capital Charges" column in the table given. It is based on a charge of 7 per cent. to cover interest, sinking fund, &c., on a capital outlay of £120 per kilowatt of maximum demand. With further reference to the five classes of consumers, A, B, C, D, and E, by adding the two sets of charges together, the total cost, including capital charges, comes out as follows:—

	Station Cost per Unit.	Capital per Unit.	Total.	Total Cost of above Supplies.
A	2·02d.	2·19d.	4·21d.	£5,788
B	1·64d.	1·72d.	3·36d.	6,496
C	0·85d.	0·81d.	1·66d.	2,766
D	0·54d.	0·5d.	1·04d.	979
E	0·49d.	0·45d.	0·94d.	2,271
				£18,300

The costs for public lighting do not include lamp maintenance.

The 2,000,000 units collectively at an average price of 2·188d. give a total of £18,233, which is sufficiently near for corroborative purposes.

In the circumstances under discussion, it would appear that a fair selling price per unit for such supplies, whilst leaving a margin of profit, would be:—A, 4½d.; B, 3½d.; C, 1⅞d.; D, 1⅛d. to 1¼d.; E, 1d. to 1¼d.

The author's investigations of the maximum demands of all these phases of supply brought to light a peculiar coincidence, in that the sum of all the maximum demands was almost exactly twice the actual maximum demand of the station, which would seem to prove two things: first that the top peak is not the only determining feature in fixing a price, and secondly that the diversity factor of a power and heat load is good.

DISCUSSION.

Mr. A. M. TAYLOR (Assistant Electrical Engineer, Birmingham) said he was particularly interested in the case of the restricted-hour power consumer; unfortunately, however, he was under interdict not to mention the word "accumulators." He was in hearty agreement with the author's statement that good business was often lost by trying to obtain too high prices for power supply; but, strange to say, the author, having worked out the costs in connection with a particular consumer at 0·608d., became afraid of his own figures, and had said, "This would appear to be, and is, too low." Mr. Taylor did not agree with this, but thought the price too high. He thought that it was correct, however, that this particular consumer should be charged nothing for the generating plant at the station, because he made no demand upon it, owing to his not taking supply at peak time. He would say that this class of consumer should not have to pay the full value of the "fixed" charges either. After having arrived at the fuel costs for the extra units, they should then take all the other fixed charges of the station and allow such consumers a rebate of 100 per cent. off these. There was another class of consumer who kept on during the whole 24 hours with a 100 per cent. load factor, if reckoned on the day's rating. According to the author, this consumer should get the best terms, but Mr. Taylor suggested that this would not be correct, for such a consumer would not improve the diversity factor. A consumer coming on in the middle of the night with a load of 4,000 kw. between 1 and 5 a.m., would cost the station about £300 per annum, whereas a consumer with this load throughout the 24 hours would cost the station £30.000 per annum. A very important point arose in connection with this, viz., how far could this night load be allowed to extend, and from a curve which he exhibited he deduced that it could be extended to about 3.30 in the afternoon. He would secure such consumers by offering a discount of 100 per cent. off the fixed charges, if they kept off between the hours of 3.30 and 5 p.m., on condition that the electricity department was allowed to revise the time they kept off every year, if it were found desirable, by simply altering the time switch, or a discount of 80 per cent. with the right of revising the "keep off" time every five years.

Mr. H. RICHARDSON (Chief Electrical Engineer, Dundee) said there was in the air an unreasoning desire for cheap units, for cheaper units, and for units which are still cheaper, and they would soon be getting to a time when customers would be required to be paid for taking the energy. In view of this craze—he could call it by no other name—he would remind them of an old north-country watchword, "caution." Nevertheless, he agreed with Mr. Pearce, who, in his Presidential Address, had questioned whether it was wise to debit large consumers with the same proportion of the standing charges that was put upon the small consumers. Large consumers should be considered on their merits in the same way that an ordinary business man would consider specially large orders. He would fix a price, an equitable price, make it as high as possible, and get it if he could. Were they, he asked, not being bluffed in many cases into supplying energy too cheaply. In connection with the Paper, he would like to mention another watchword, viz., "simplicity." Simplicity in plant was absolutely essential to success, and simplicity of charges would be still more beneficial.

Alderman W. HIGHAM (Chairman of the Accrington Electricity Committee) said they were in a fool's paradise entirely if they thought they would get a manufacturer in Lancashire or anywhere else to take current at the prices which had been asked hitherto. In Accrington they had been giving power supply during the past four years at 0·68d. per unit, and the results had amply justified the price. The Lancashire Power Co. was asking too high prices to get the Lancashire cotton mills, because, as a mill-owner himself, he knew that the mill could produce power with its own steam plant at 0·34d. per unit, including the warming of the mills. The prices given in the Paper were much too high. With a load-factor of 20 per cent., and coal at 10s. per ton, no station engineer should be satisfied if his coal costs exceeded 0·25d. per unit generated. At Accrington the figure was below 0·25d., and the total costs were 0·52d.; next year Accrington would in all probability have the lowest cost in the country.

Mr. E. E. HOADLEY (Chief Electrical Engineer, Maidstone) agreed that it was absolutely hopeless to go to a large and regular user of power and ask a price anywhere in the neighbourhood of 1d. per unit. In making investigations such as the author had, he would suggest that it was more accurate to take out the actual kilowatts on the peak load of each class of

Digitized by Google

demand. He had done this at Maidstone, where, by taking the load on Christmas Eve, he had eliminated the power supply. He had then worked out the capital and standing charges which ought to be paid by each class of supply. In order next to arrive at the actual cost of producing the units, he had taken six Saturday nights and six Thursday nights between the hours of six and ten p.m., and, taking the actual difference in costs between the Thursday night and the Saturday night, it was a very simple matter to arrive quite accurately at the actual cost of producing the extra units which were generated on the Saturday night. It was this cost which must be known very accurately before they could set out a scale of charges for the large and regular power-users. He did not agree with a two-rate system of charging for these consumers, because, unless the high rate was made quite prohibitive, the charging was not fair. The only way to get an equitable system of charging was to have a fixed charge per kw. demanded of peak load per annum, and a very low price per unit.

Mr. ASHTON BREMNER (Chief Electrical Engineer, Burslem) gave a few figures to demonstrate that cheap units could be sold to the advantage of small stations, as well as to the larger ones treated in the Paper. At Burslem they had the competition of gas at 1s. per thousand c. ft. Last year the load-factor at Burslem was 15 per cent., the total number of units sold being 585,000, the total costs being 0·88d. Since then he had taken on a large consumer at ½d. per unit, and the costs had gone down to 0·44d., the total costs, including capital charges for the six months, being 0·87d. per unit. Mr. Sinclair had taken public lighting with a load-factor of 46 per cent., which was too high, unless the arcs were burning all night. This particular power consumer mentioned at Burslem had a load-factor of 69·6 per cent., and on the basis of Mr. Sinclair's table the following were the figures at which he ought to supply at Burslem: 10 per cent. load-factor, 1·25d.; 20 per cent., 0·636d.; 30 per cent., 0·486d.; 50 per cent., 0·297d., without capital charges. The figure of £120 per kw. for capital expenditure taken in the Paper was too high. At Burslem it was £50, and, taking the author's figure of 7 per cent. for capital charges, which he thought fair, this would make the total charge, at 50 per cent. load-factor, 0·484d. per unit.

Mr. W. W. LACKIE (Chief Electrical Engineer, Glasgow) disagreed with the author that the load factor of each consumer was not readily obtainable. The maximum demand system enabled this to be done. He would not like it to go out from the Association that the proper way to charge a consumer was according to the hour he closed his shop, nor was it fair to charge a small consumer more than a large one, if his load factor was better. Some ten years ago Mr. W. A. Chamen, who was then Electrical Engineer to the Glasgow Corporation, tabulated the whole of the consumers, and allocated them according to trades, and found there was only one class of consumer who could be classified, and that was the domestic consumer. Therefore, he was strongly of the opinion that each consumer should be charged according to his load factor; and that all should bear their fair share of the capital charges. He thought the whole crux of the matter of charging consumers who kept off the peak load was to sell their energy at a lower cost than they could generate it themselves. These midnight consumers were bakers and such like, and he was perfectly certain they would be glad to pay 1½d. or 2d. per unit. At Glasgow they charged them 1½d.

Mr. G. SEATON (Messrs. Willans & Robinson, Ltd.), confirmed the author's low figures of costs at Stalybridge, and gave the following details:—Coal, 0·18d.; oil and waste, 0·01d.; wages, 0·06d.; repairs, 0·04d.; rent, rates, &c., 0·4d.; management, 0·04d.; total, 0·37d. per unit. At the same time, he did not consider the figure Utopian at all. Given the same load factor as at Stalybridge, viz., 26 per cent., coal at the same rate, and cold water instead of lukewarm slime, these figures could be considerably improved upon. In the Paper, Mr. Sinclair got a bit Utopian himself. In England, late closing shops were not allowed. At the Midland Hotel, Manchester, the chucker-out finishes his business at 11.5 p.m. sharp, at which time the all-night load just began on the Continent.

Mr. R. B. LEACH (Chief Electrical Engineer, Farnworth) mentioned an unfortunate experience with time rate meters, which had resulted in getting a false peak, this occurring at ten minutes past nine instead of between five and seven p.m. Differentiating between various classes of consumers was a dangerous practice, because they had no right to penalise any consumer. They must give their largest customers the best terms, keeping the load factor well in mind.

Mr. F. W. PURSE (Chief Electrical Engineer, Watford) said that all this talk of exceptionally cheap units made it hard for the small station. They got manufacturers coming down and saying they proposed to erect works, saying they could get a supply for such and such a low figure in some other towns. He knew of a case in which the engineer had been driven to grant such low terms that he lost heavily on the transaction. The President had referred to their want of commercial capacity; this was essentially a business matter, but many of the suggestions for dealing with the question were not business propositions. The speaker from Accrington had referred to the low prices at which certain Lancashire mill owners could generate for themselves, but even at Warrington consumers were paying ½d. or ¾d. per unit, and were perfectly satisfied.

Mr. S. E. FEDDEN (Chief Electrical Engineer, Sheffield) said that demand indicators, low-rate switches, and such like ought all to be put on the scrap-heap. They had heard all sorts of fakes for charging, but he did not believe in "come on" or "keep off" discounts. He believed in setting a certain price for lighting and another for power, and when they had special consumers with special loads, then dealing with them in a special manner. This was not preferential charging, because they were perfectly willing to give the same terms to others in the same circumstances. A lot had been heard about consumers' load factor. The generality of shops had a miserable load factor, and in Sheffield they were 5 per cent., 7 per cent., and 13 per cent.; there were very few much over 20 per cent., and then they were for blowers or furnaces, but they all levelled up at the station. At Neepsend, where 4,000 kw. of power were supplied all day long, the load factor was from 40 to 50 per cent. The load factor for the whole of the year, with the lighting, was only 15 per cent. Surely, therefore, he could make a special price to the power users.

Mr. H. FARADAY PROCTOR (Chief Electrical Engineer, Bristol) expressed his agreement with the view taken in the President's Address that, as the power load was a newer load in many towns than the lighting load, and was supplied by more up-to-date plant, the capital charges could be taken upon a much lower basis.

Alderman BRUCE (Chairman of the Electricity Committee, Sunderland) said municipalities had to consider in this connection whether they would place themselves in line with large companies, or whether they were prepared to allow legitimate business to pass to the companies. He did not consider the prices suggested by Mr. Sinclair at all tempting to power users. The Sunderland Committee had recently quoted two large power users, one a paper works and another a flour mill, £4 per annum per kw. of maximum demand to cover standing charges, and a very low charge per unit. An agreement for 15 years had been entered into. Unless municipalities were prepared to cater for large power users, they had no right to refuse to allow a power company to come in.

Councillor SINCLAIR replied briefly, promising to amplify his remarks for the Association's *Proceedings*.

The meeting then adjourned, and the members proceeded to the Town Hall, where they were entertained at luncheon by the Electricity Committee of the Manchester Corporation.

COUNCILLOR S. W. ROYSE, in proposing the toast of the Incorporated Municipal Electrical Association, said that a municipality should supply electricity at cost price, after providing for sinking fund, renewal fund, &c. He knew that in this opinion he was at conflict with the Lord Mayor, but he maintained that it was with this object that a local authority was given a monopoly of electric supply in its area. Mr. S. L. PEARCE, in the course of his reply to the toast on behalf of the Association, said that 75 per cent. of the capital invested in electricity supply and tramways in this country was in municipal undertakings. The Incorporated Municipal Electrical Association should therefore have a voice in any matters affecting the electrical industry, and it must be remembered that, unlike the Institution of Electrical Engineers, the Association dealt with commercial as well as technical questions. ALDERMAN G. PEARSON, Chairman of the Bristol Electricity Committee, proposed the toast of the Manchester Corporation Electricity Committee, which was replied to by COUNCILLOR KAY (Deputy Chairman of the Manchester Electricity Committee), in the absence, through indisposition, of the Chairman, Councillor Howarth.

In the afternoon inspections were made of the Stuart Street, Dickinson Street, and Bloom St. works of the Manchester Electricity Department, where Mr. Pearce, Mr. McKenzie, and Mr. Whysall, together with their staff, were indefatigable in showing and explaining the plant to the visitors. Particular interest was directed to the rotor and parts of the stator of the new 6,000-kw. Howden-Zoelly-Siemens turbo-set, which have recently arrived at the works and are awaiting erection.

On Wednesday, the Association met in the St. George's Hall, Lime Street, Liverpool, where two Papers were read and discussed. The first was by Mr. E. E. Hoadley, Chief Electrical Engineer to the Maidstone Corporation, and dealt with the question of metal filament lamps, and the second Paper was on "Modern Cable Systems," by Mr. E. M. Hollingsworth, Chief Electrical Engineer to the St. Helens Corporation.

THE INFLUENCE OF METALLIC FILAMENT LAMPS ON THE ELECTRICAL INDUSTRY AND ON STREET LIGHTING.

BY E. E. HOADLEY.

(Chief Electrical Engineer, Maidstone.)

From the point of view of most manufacturers of generating plant the metal lamp is anything but a blessing. For the past two or three years extension of plant, except in a few favoured localities, has been slow enough, due no doubt to the prevailing slackness in nearly every trade and the general tightness of money; and on top of this comes an invention which, if it does anything at all, will certainly keep the peak load in a generating station from rising at anything like its normal rate for a year or two to come, and in many cases will actually reduce it; and it is the peak load which determines whether extension plant is wanted or not. Cable makers may not be so unfortunate, as with the undoubted lessening of lighting cost to the consumer, people who have hitherto held back on the score of price may become consumers; and to supply them mains will have to be run.

On the manufacturing side, the reapers of the harvest brought about by metal lamps will be first and foremost the lamp makers themselves, who, at the prices now ruling, should shortly be able to give lamps away; next the accessory makers should feel a distinct benefit from the introduction of the lamp, as it is an assured fact that the number of users of electric light will be largely increased. Although not directly affected by the lamp *per se*, the author has very little doubt but that the makers of motors and of cooking and heating apparatus will be beneficially affected by its introduction. The wiring contractor does reap a decided benefit from the introduction of the new lamp.

We now come to the point of view of the supply station engineer. It is undoubtedly the single-phase alternating-current stations which will feel the pinch first and will feel it hardest, as practically all the circumstances are against them. Speaking of them generally, the class of property they supply is of the better class, houses whose owners will face the outlay demanded by a transformer and metal lamps with equanimity. Not having a large late-closing shop demand, the raising of the standard of illumination will not help them very much, as the consumer will go in for the same amount of light for a greatly reduced amount of money. In the generality of the towns in question gas is not particularly cheap, so that a large proportion of the available houses already take a supply, so purely from the lighting supply it is doubtful if new consumers will come along fast enough to take all the units that existing consumers will save; even if they do, it means that the capital charges per unit sold will be increased, as new mains and services must be provided and in these residential towns these are generally an expensive item per consumer, and with the poor load factor generally prevalent capital outlay should be kept as low as possible.

It can hardly be wondered at that several stations of this class are considering the raising of prices. In some special cases this may be the right policy, but the author is of opinion that what may be called the domestic uses of electrical energy should be pushed as widely and as hard as possible—heating and cooking in the better class houses are not exploited nearly as much as they should be.

Where an alternating-current station has the benefit of a good shop lighting load and at the same time supplies a fair amount of power, the metal lamp should be looked on as a blessing—in disguise for a short period, if you will—but still as a blessing, for the amount of harm done to the revenue account now will be amply repaid later on.

Most engineers of continuous-current stations, particularly of those where the pressure is 200 volts or over, look with distinct favour on the lamp, but even they must look further than some of them have done up to the present. The effect of the metal lamp must be looked for not as it is just at present, when the smallest high voltage lamp made is in the nature of fifty candle-power, and costs 4s. 9d., but the time must be faced when a lamp of sixteen candle-power or even smaller can be obtained for all pressures commonly in use and at a price which will be but little in advance of the selling price of the ordinary carbon filament lamp. The gas mantle is an article quite as fragile and as intricate as the metal lamp, and yet to-day it sells for less pence than it did shillings when first introduced. The author can remember carbon lamps selling at 5s. retail, and in the course of fifteen years this has been reduced to something less than 9d. In spite of what the lamp makers say as to the fine margin of profit at present prices, the reduction is bound to come.

The station engineer ought to be quite ready for this, and it must now be considered how this is to be brought about. The first and foremost necessity is that municipal bodies generally should have the power to raise money for the purposes of wiring houses and other premises, for letting out cooking and heating apparatus, as well as motors on hire and hire-purchase. Most municipal bodies would be quite satisfied if the powers were granted with the proviso that the wiring work should be done by contractors; with regard to cooking and heating apparatus how many contractors could truthfully say that an appreciable source of income will be taken from them if the supply authority is allowed to hire heating stoves, ovens, and things of like nature, it being understood that the wiring for these is done by a contractor. In this connection, if it be good law for some forty-four towns to possess these powers, then how stupid and how typical of British legislation it is for the rest to be denied them unless they go to the expense of a Special Act; further, if it be fair and just for the gas companies themselves to do all these things and many others besides, is it more unfair to the electrical contractors than to gas fitters, that electricity supply authorities should possess equal or similar powers. Electrical engineers have too long been content to sell the consumer electricity whether it is light or heat that he buys, and it is vital to the interest of the supply authority to see that he is satisfied with the amount of heat or light that he gets for the money he pays. But how can this be done when the supply authority is bound down by silly restrictions, and is spied upon at every step by the officials of the local gas company to see that these restrictions are not broken? A determined effort should be made to get these necessary powers—necessary at least to all supply authorities except those in our large manufacturing towns where the connecting up of consumers of a quarter or half a million units annually excites no comment.

Next to the above comes the necessity for cheaper wiring. With many people who are willing to believe that the cost of electric lighting is no more than gas lighting, the cost of wiring their premises has certainly in a large number of cases been a real stumbling-block. Whatever be the system or systems of cheap wiring that will survive and become standard, the author can state from his own experience that the Continental system of flexibles on special insulators requires a lot of beating—among other places, he has tried it in the damp warm atmosphere of a conservatory for eighteen months without the slightest trouble. With cheap wiring, the necessary powers to hire out cooking and heating apparatus, wiring, and fittings, and the improvements in cooking and heating apparatus which are bound to come with extended experience, most central stations should be able to look on the metal lamp as an ally and not as an enemy; to the above advantages should be added the very important fact of a large reduction in the selling price of the lamp, for what is the use of talking to a working man earning 30s. a week of the cheapness of electric light when he has to pay 4s. 9d. for a new lamp? From 8d. to 10d. a week is about the average revenue obtained from this class for light, and a gas mantle can be got for 4d.

That there will be a diminution in revenue from lighting consumers cannot, the author thinks, be denied, as although the standard of lighting demanded will undoubtedly be increased, yet it will be in very few cases that the standard of illumination will be raised some three and half times, which is roughly the ratio of efficiency between tungsten and carbon lamps at present, and some makers of tungsten lamps are already considering the question of raising the efficiency of the lamp, as the average life obtained in a large number of cases points to the sale of lamps for renewal purposes being a great deal less than was estimated.

In the field of public street lighting the importance of the new invention cannot be over-estimated; up to the present its full effect has not been considered and the author feels sure that when engineers and committees responsible for the lighting of streets have fully realised the possibilities of a lamp with an efficiency of approximately one watt per candle-power, that can be obtained in single units giving candle-power ranging from fifty to a thousand, there will be many schemes of street lighting by arc lamps and by incandescent gas that will be altered and modernised.

In going about the country the author has seen many streets lighted by enclosed arc lamps and by alternating-current arc lamps which are not successful, from purely a lighting point of view, without in any way considering the question of cost per street mile. In most of these cases the whole effect to be obtained can be reconsidered, bearing in mind the new weapon that has been put into the hands of the responsible parties.

Up to the present the generality of streets lighted by incandescent gas at ordinary pressures in towns where electric light mains are laid, are so lighted on the score chiefly of cheapness, the supporters of gas lighting claiming that electric light was beaten in the competition, as the light given by carbon or other lamps available up till recently was not equal to the light of an ordinary gas mantle; while for many streets the cost of arc lighting, even with the lamps spaced as far apart as possible, was prohibitive. Whatever truth there was in these statements then has considerably altered now, for an ordinary sixty watt metal lamp without any reflector will, from the point of view of the ordinary public, produce the same results as a good gas mantle in the heyday of its youth, while with reflectors the effect can be considerably increased. The other advantages, from an electrical point of view, are that no special mains are necessary; with the same fitting, different candle-power lamps, graded according to the importance of the streets, can be employed; lamps that fail can be renewed at any time without trouble; the candle-power of the lamp does not appreciably

Digitized by Google

diminish with age; and last but not least, the average life of the lamps is a revelation. In the author's own experience, some eighteen months has given an average life of very nearly 1,100 hours, individual lamps lasting 6,750, 5,450, and 5,044 hours on a circuit at 230 volts where a large and fluctuating power demand does not make for a particularly steady volt chart.

In conclusion, the author would urge all station engineers to unite in trying to obtain what he considers the necessary powers to enable them to utilise to the full the immense power put into their hands by this epoch-marking invention, and by themselves getting into personal contact with their consumers, putting before them the great advantages of more light for the same money instead of the same light for the less money.

MODERN CABLE SYSTEMS.

By E. M. HOLLINGSWORTH.

(*Chief Electrical Engineer, St. Helens.*)

THE branch of electric supply that involves the greatest expenditure, and, generally speaking, is the cause of most anxiety, is the system of distributing cables. It is within the bounds of possibility that other and cheaper materials than those used at present for the manufacture of cables may be found suitable, and in these days of cheap power supply and metallic filament lamps any cheapening of the distributing system will be welcomed, but on the question of reliability, combined, of course, with cost, it hardly seems possible to improve the methods now usually adopted for protecting the cables underground.

ALUMINIUM.

For overhead transmission lines aluminium has been used for many years with satisfactory results. The metal is also being used for bus-bars, lightning arresters, fuse strips, &c., but until quite recently it had not been tried for the conductors of insulated cables.

Compared with copper conductors of equal conductivity, aluminium conductors are 50 per cent. lighter in weight, and 28 per cent. greater in diameter. Beyond a probable saving in carriage, the reduced weight does not affect the question of insulated cables—that is, with copper and aluminium at present prices. In the matter of increased diameter the advantage of a greater cooling surface is obtained, but against this there are the extra insulating and sheathing materials required, and the necessity of using troughs or conduits of larger size.

From the experience obtained with overhead conductors, the behaviour of the metal is such that it should be quite as reliable as copper for the conductors of insulated cables, provided, of course, that the insulating materials are free from any matter that might cause deleterious action.

There is some little difficulty in the matter of jointing and making connections to the conductors. So far a satisfactory solder has not been produced, and, therefore, the joints have to be made by means other than those usually employed for copper conductors. For cables of large section liable to be subjected to considerable strain the mechanical joint is the most satisfactory, and for this purpose clamps of aluminium should be used in preference to those of brass or copper in order to prevent oxidisation, which is likely to be set up when there is contact between these metals and aluminium. For cables of small section the joints can be made on the moulded principle, molten aluminium heated to a dull red being poured into an iron mould, in which the cable ends have been clamped. In any case it is very probable that the joints will require more skill and will take longer to make than in the case of copper, and will, therefore, be somewhat more expensive.

The question as to whether aluminium is likely to be adopted for insulated cables must depend to a great extent upon financial considerations. With copper at the price of £60 per ton and aluminium at £65 per ton, there is an advantage in favour of the latter for single-core cables above the equivalent of 0·05 sq. in. of copper. Taking cables having the equivalent of 0·1, 0·2, and 1 sq. in. copper conductors, there is a saving of 15, 20, and 30 per cent. respectively. In the case of triple concentric and three-core cables the difference is not so great.

RUBBER INSULATION.

For underground work, rubber-insulated cables have almost entirely dropped out of use, chiefly owing to the fact that they are considerably more costly than vulcanised bitumen or paper insulated cables, and that they have not proved permanently satisfactory. Rubber rapidly deteriorates when subjected to the action of acids, varying temperatures, or the alternate dry and moist conditions that prevail underground. In some cases the use of rubber cables has been continued with satisfactory results. Mr. Highfield informs the author that the Metropolitan Electric Supply Co. has some rubber cables working at 3,000 volts which have been in use for over 18 years, but this is a very exceptional case.

VULCANISED BITUMEN INSULATION.

Compared with paper insulation, vulcanised bitumen claims the advantage of being absolutely non-hygroscopic, thereby obviating the necessity for lead sheathing, but too much reliability must not be put on this material to exclude moisture permanently, for although moisture that is neutral, or acid, has little or no action, moisture that is at all alkaline will attack this cable, and under certain conditions rapid deterioration takes place, the material becoming a spongy mass and of course no longer waterproof. It is certainly the best plan to lay vulcanised bitumen cables underground on the solid system to prevent as far as possible contact with deleterious matter.

These cables are very extensively used in collieries where the conditions generally are damp and where in the case of the pit shaft the question of weight is an important factor, for a single core vulcanised bitumen cable of 0·1 sq. in. section is only half the weight of the equivalent paper insulated lead-covered cable.

Such cables should be handled very carefully, more especially in cold weather, otherwise the insulation is liable to crack. When laid on the solid system they should be supported at distances short enough to distribute the pressure and prevent possible decentralisation. This may also be caused by defects in manufacture or on account of an abnormal rise in temperature, the results of overload or short circuit, but with a good make of cable there is very little risk. Unfortunately, this class of cable has to be bought more or less on faith, for it is a difficult matter to distinguish between a good and inferior cable, and the only test is that of constant use and time.

Cables suitable for a working pressure of 600 volts should be tested at the makers' works to at least 2,500 volts A.C. for half an hour. The insulation resistance for a 0·1 and 1 sq. in. cable should not be less than 100 and 50 megohms per mile respectively. The use of a paper separator will increase these figures. At 60° F., it should be possible to bend an all bitumen cable round its own diameter several times without fracturing the insulation, but if a separator is used the test will be limited by the material of which the separator is made.

PAPER INSULATION.

For all systems and pressures paper insulation is used. The chief drawback to this class of insulation is that the reliability of the cable is dependent upon the sheathing remaining intact, and, therefore, great care should be taken to prevent it being damaged. Precautions must also be taken when jointing such cables to protect the exposed paper from moisture, otherwise there will be a drop in the insulation resistance and probably a breakdown later on.

Considering the quantity of such cable in use, there have been, comparatively speaking, few causes of trouble from electrolysis. It cannot be denied that there is a danger of electrolytic corrosion particularly where the cables are laid in the neighbourhood of a tramways system, but if the precaution is taken of solidly bonding the lead sheaths and connecting them at suitable points to earth plates, the risk is reduced to a minimum. In the matter of bonding, the sheaths cannot be connected too frequently, and the bonds should err on the substantial side to ensure as low a resistance as possible. Whatever arrangements are to be made at the joint and disconnecting boxes, it is also advisable to bond across them as an additional precaution. Good sturdy bonds of lead strip are far superior to copper wire. They have the advantage of being of the same metal as the sheathing, and therefore less skill is required to make a connection to ensure permanent contact without injuring the cable.

There should, of course, be considerable discretion in the placing of the earth plates, otherwise the dangerous conditions may be intensified rather than reduced. Each case must be decided on its merits, that is, from the results of the tests taken as to the polarity of the lead sheaths and earth. Likely places are those where the cables cross under a tramways track or are laid in the vicinity of negative feeders, for in the majority of such cases the lead sheaths will be found to be positive to the track. It is advisable to keep a record of all the earth plates, and they should be tested as frequently as possible to see that the conditions remained unchanged. The earth plates may consist of copper or lengths of cast iron pipes placed vertically in the ground, and surrounded with finely crushed coke, brickbats, and in some cases chalk. These earth plates are usually connected to the lead sheaths by means of a substantial copper conductor, and in the case of the cast iron pipe contact is made by fastening a rail bond to the socket of the pipe.

With reference to the leadless sheathing, this is certainly a great advantage as far as prevention of electrolysis is concerned, but such cable is not mechanically as strong as that with the lead sheathing, and in certain localities there is risk of chemical action.

SYSTEMS OF LAYING CABLES.

The manner in which cables are to be laid is not materially affected by the system of supply adopted, but is influenced more by the conditions existing in the locality. In St. Helens the conditions are as unfavourable to underground cables as it is possible to have them. It is a colliery district, which means that the ground in places will subside from time to time, and one of the principal industries is the manufacture of

Digitized by Google

chemicals, in connection with which there are eight large works. It will be realised from this that the ground in the neighbourhood of these works cannot fail to be impregnated with acids and alkalis.

Although comparatively little armoured cable laid direct in the ground is in use at St. Helens, it has given more trouble than all the rest of the network. For one reason, the soil, being impregnated with acids, quickly rotted away the jute covering, and in places the armouring entirely disappeared. In nearly every case the faults occurred in single-cored cables, the triple concentric cables giving little or no trouble. It must be admitted that ten or eleven years ago the manufacturer did not pay that attention to the armouring of the cable that it is receiving at the present day, and probably the importance of bonding and earthing the lead sheathing and the armouring was not then realised.

On account of the thickness of the layers of jute and the dimensions of the armouring now being fixed by the Engineering Standards Committee, and the cable manufacturers taking greater care with respect to the quality of the materials and their application, many engineers have more confidence in this class of cable, with the result that it is being more generally adopted for all systems of supply.

The solid system, is very little more expensive and is almost as flexible as regards laying as the direct system, and cables laid in this way are better protected from external influences than when laid in any other way. Stoneware troughs appear to have superseded to a great extent those of wood or iron; for one reason they are as cheap as wood, considerably cheaper than iron, more durable, and, if properly glazed inside and outside, proof against chemical action. They have, however, the disadvantage of being only about 2 ft. long, which, of course, means an increase in the number of joints in a given length. Butt jointed troughs should not be used. The author has experienced considerable trouble with certain lengths of cable developing faults attributed to moisture getting in at the joints owing to the careless laying of the troughs.

Of course, for bitumen cables, bitumen filling is used, but, comparatively speaking, very little bitumen is now used with lead-covered cables, good pitch reduced by a suitable oil being found satisfactory and very much cheaper. Pitch has also had the advantage of a lower melting point than bitumen, and does not require the same care in filling, and in the case of a fracture there is a better chance of it healing again. To reduce the cost still further, some engineers use a mixture of sand and tar, but as this requires to be kept in a constant state of agitation, and even then does not flow as freely as pitch, there is some risk attached to its use.

The minimum thickness of filling should not be less than half an inch, and to ensure an even thickness the bridge pieces should be placed at suitable intervals, usually 18 in. apart, but never exceeding 2 ft., depending upon the size and weight of the cable. It is absolutely necessary that the bridge pieces should not be porous, as a great deal of trouble has been caused owing to faults developing at such places. There is very little to choose between the properly compounded wood pieces and those made of glazed stoneware. Asphalt pieces are probably the best, but are considerably more costly. Another support which is being used very extensively is the "Ruthven Murray" iron strap, the use of which ensures the filling getting all round the cable, but it is of importance that the iron strap and lead sheathing should be in clean contact, otherwise local electrolytic action may be set up.

When cables are laid through a busy thoroughfare, or where a great many of them are banked together, the system in which they are drawn into conduits or pipes is the only one suitable. This system is the most costly in the first instance, but it provides for future extensions, and it admits of the cables being got at in case of breakdown without disturbing the street. Unfortunately, in practice it is not possible to lay conduits through a street for any great distance and maintain a straight course, and, therefore, on this account many manholes are required, which considerably adds to the cost. There is also the question of keeping the conduit dry and free from gas, a very difficult matter, but one that is met to some extent by sloping the conduit, and draining and ventilating the manholes. Some engineers, where possible, construct conduits of greater height than width, thus having the fewer ways, which will be the wet ways, at the bottom.

A conduit constructed of cast-iron pipes gives good mechanical protection, and, compared with stoneware, has the advantage of fewer joints, but it is more expensive, and does not give that secondary insulation which is a great advantage in some cases. On several occasions the author has found it impossible to draw out of a cast-iron pipe a length of cable that had failed. Apparently the lead of the cable had soldered itself to the pipe.

The author has had no experience with fibre ducts treated with bituminous compound, but understands that they are satisfactory when laid in concrete, and cheaper than iron pipes. It is claimed that they are proof against acids and alkalis, and that they do not absorb moisture to any extent.

The stoneware conduit is made in single or multiple form. Where a great many ways are required one good method is to build up in concrete with single ducts the number of ways required, care being taken to prevent the cement at the joints from entering the ducts. This type, provided not less than nine ways are installed, represents the cheapest form of conduit.

The manholes should be as roomy as possible, and so designed that it is not necessary to "short bend" any of the cables, and in all cases cables should be properly separated to protect them from the danger which may arise from the failure of an adjacent cable. It is also the practice of some engineers to cover the cables from side to side of the manholes with asbestos braid, and then to coat them over with a special paint.

The large-sized covered cables that are drawn into conduits should not be jute covered, as there is a tendency for the covering to be torn off and to jamb the cable, but in the case of small service cables where the lead is comparatively very thin a jute covering is necessary for mechanical protection.

SUBWAYS.

Whichever system of underground cables is adopted there is always the question of future extensions, a very difficult problem when considered in connection with some of the streets where the underground structures are already very much congested. For this reason the author thinks that subways are likely to be more generally adopted in the future, and, therefore, a short description of the one in use in St. Helens may be of interest.

There is in St. Helens down the two principal thoroughfares a subway, 6 ft. 6 in. high, and 5 ft. 6 in. wide, nearly half a mile in length, with an entrance at each end and one midway, and with lateral ways at the intersections of the other streets. With the exception of a 4½ in. ring of blue bricks forming the inner arch it is constructed entirely of concrete, and the form of construction and arrangements of the gas and water mains and electric cables are as shown by Fig. 1. For the

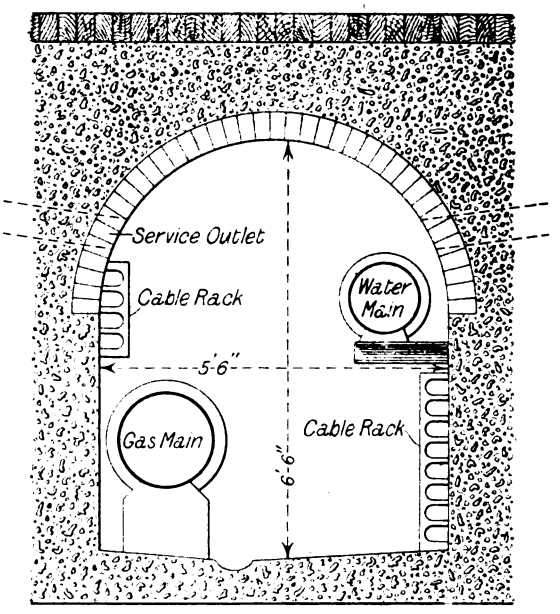

FIG. 1.—CROSS-SECTION OF SUBWAY.

gas, water, and electric service connections, 6 in. earthenware pipes are laid at frequent intervals from the subway to the footpath. It is ventilated by means of open gratings placed about 30 yards apart, and is, of course, lighted by electricity.

The work was completed in 1899, and the cost, including the lateral ways, was £7 per lineal yard, and the Electricity Department's share of the capital and maintenance charges is £90 per annum. At the present time, exclusive of service connections, there are four miles of cables ranging from 0·1 to 1 sq. in. single and multi-core. The cables are supported on strong racks, and the average cost, including the racks and the placing of the cables, is about 1½d. per yard of cable. The feeders and distributors are connected to distribution boards placed in a chamber at the centre entrance to the subway. About one hundred consumers are supplied through services connected to the mains of the subway. Large three-wire consumers are in each case connected direct, but in the case of small consumers three or four are supplied from one set of service cables.

The close proximity of the cables to each other and to the gas mains has been advanced as an objection to such a system, but so far the author has not experienced any trouble, and he considers that if ordinary care be taken this risk should be very remote.

COMPARATIVE COSTS OF CABLE SYSTEMS.

It was the author's intention to try to define the present practice as to types of cables, and methods of laying adopted

Digitized by Google

for the different systems of supply, but he finds that the practice is still so varied that the idea had to be abandoned. The following table shows the comparative costs of some of the different types of cables and methods of laying them.

DISTRIBUTION AND SERVICE CABLES—COST PER MILE.

Area of each Conductor.	Type of Cable.	Cost of Cable only. Plain Lead Covered.	Cost of Cable only. Armoured.	Total Inclusive Cost of Armoured Cable laid direct.	Total Inclusive Cost of plain Lead Covered Cable laid solid in Earthenware Troughs with Pitch Filling.	Total Inclusive Cost of Cable drawn into 3" Earthenware Ducts, each Cable in separate Duct, including Draw-in Boxes in Footway.

NOTE.—Electrolytic Copper Bars taken at £70 per ton and Lead at £15 per ton. The cost of Disconnecting Boxes and Trenchwork is not included. All Cables are taken as being Paper Insulated, Lead Covered. There is very little difference in cost between such cables and bitumen. In case of Three Singles, Three-Core and Triple Cables, the neutral conudctor is taken as :—·025 □ " for (a), ·06 □ " for (b), ·10 □ " for (c), ·20 □ for (d).

OVERHEAD CONDUCTORS.

Before concluding, the author would like to refer to the value of overhead conductors for supplying isolated districts, and to give a brief description of the system that has been in use in connection with the St. Helens Corporation scheme since 1902. By means of overhead conductors, a supply of energy at 500 volts direct current, with one side earthed, is given to several glass works and collieries situated within a radius of two miles from the power station, but separated by rough

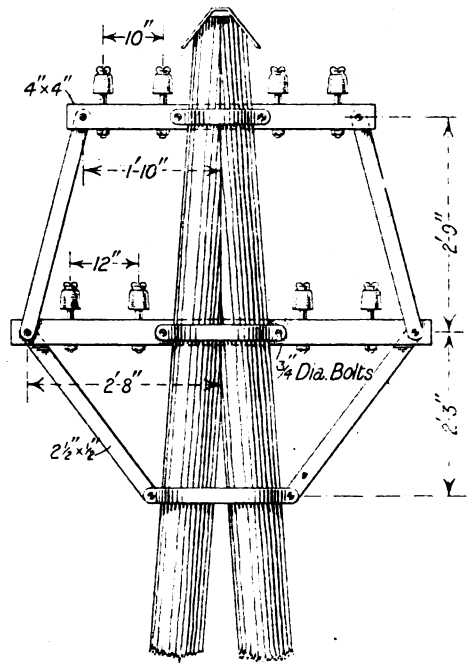

FIG. 2.—ARRANGEMENT OF CROSS ARMS.

ground impregnated in places with chemical waste. For this reason, it was quite out of the question to lay cables underground, and the Board of Trade being convinced of this consented to the conductors being placed overhead.

The total length of the pole line is just over 1½ miles, and the poles are placed about 40 yards apart. The dimensions of the poles and cross arms and the arrangement of insulators and conductors are shown by Fig. 2. The poles are of red fir, well creosoted, and are to the specification issued by the General Post Office in connection with the supply of telegraph poles. They are planted to a depth of 8 ft. with a packing of concrete, and about every two years the base of each pole is exposed to a depth of about 2 ft. and coated with oil of creosote. Apparently so far there is little or no deterioration, which undoubtedly is due to the process of creosoting these poles, for by some misunderstanding one or two poles that had not been treated were erected, but after six years' use they had to be replaced. The cross arms are of creosoted oak with stays of wrought iron, and the insulators are the Post Office heavy telegraph type. The conductors are 4/0s. S.W.G. solid drawn copper, staggered in order to comply with the Board of Trade Regulations Three pairs of conductors are in use for a portion of the distance, and there is room for another pair, or four pairs in all.

The cost of the work, exclusive of the conductors, was £220 per mile, and for each pair of conductors erected must be added £170 per mile. If copper conductors were replaced by aluminium at present prices, the cost would be for each pair of conductors £120 per mile. For comparison the cost for the equivalent underground mains, that is, two 0·15 sq. in. cables, laid solid in earthenware troughs, would be £800 per mile. From these figures it will be seen that the installation of overhead conductors is considerably less expensive than in the case of underground cables, and in addition the cost of maintenance is less, and such a system offers more flexibility and less risk of breakdown.

Obituary.—Mr. George Frederick Deacon, M.Inst.C.E., died suddenly at his offices, 16 Great George Street, Westminster, on Thursday last. Mr. Deacon went on the s.s. *Great Eastern* as an assistant to Lord Kelvin on the occasion of the laying of the Atlantic cable in 1865. He was appointed borough and water engineer of Liverpool in 1871, and carried out the great water scheme at Vyrnwy in 1877. He was the recipient of the Telford, Watt, and George Stevenson medals of the Institution of Civil Engineers.

Glasgow Section I.E.E.—The annual excursion of the Glasgow section of the Institution of Electrical Engineers, took place last week, jointly with the West of Scotland Iron and Steel Institute, when a party of about 260 cruised in the Firth of Clyde, on the Caledonian Railway steamer *Duchess of Hamilton*. Among the party were Mr. W. W. Lackie, Chief Electrical Engineer to the Glasgow Corporation, and Chairman of the Glasgow Local Section; Prof. Magnus Maclean, of the Glasgow and West of Scotland Technical College; Mr. E. G. Tidd, Chairman-elect of the Glasgow Local Section; and Mr. J. E. Sayers, local honorary secretary of the section.

THE CONDITION OF THE ELECTRICAL INDUSTRY

Mansion House Meeting to be held

AT the instance of Sir William H. Preece, K.C.B., the Lord Mayor has consented to invite the leading banking and financial authorities to a meeting at the Mansion House to consider the want of confidence that exists between capital and home electrical industry, the causes for this unsatisfactory condition, and the remedies. It is probable that the meeting will be held early next month.

Sir William Preece has also expressed his willingness to entertain the suggestion that he should accept the presidency of an organisation formed for the purpose of protecting the general commercial and financial interests of the electrical industry of the Empire.

He has sent us a copy of a letter addressed to a small provisional committee of a few leading men in the manufacturing and other branches of the industry, in which he says:—

I agree with you that while the technical development of the electrical industry is well provided for by the Institution of Electrical Engineers and its allies, there is a pressing and immediate need for some organisation whose aim should be to impress the general and financial public, and especially Parliament, with the vast commercial interests represented by the industry. There are two important questions involved:—

Firstly: The broad imperial industry affecting both home and colonial markets now deeply depressed by ignorance of its growth and its wide capabilities and extent. It is virtually closed to development by the practical impossibility of obtaining capital on fair conditions. Money that flows freely to our colonies and to foreign countries cannot be obtained for our home demands, except on exorbitant and almost prohibitive terms.

Secondly: The local home industry is dependent on mutual self-support, mutual confidence between master and man, and broad businesslike relations between the wholesale and retail elements, and between buyer and seller.

In order to bring the first of these points home to the financial and investing public, a meeting, as has already been said, will be convened at the Mansion House in the near future.

Regarding the second point, Sir William Preece says:—

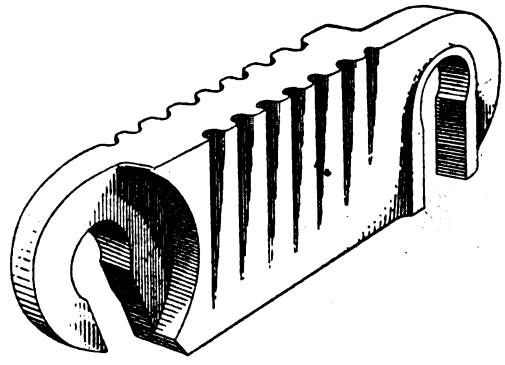
We require an association which, supported by existing societies, will bring the public voice to bear upon their representations, so as to enable deputations to Government departments, and witnesses before Royal Commissions and Parliamentary Committees, to speak, not merely with the authority of experts, but with the force and weight of numbers from all sections of the industry.

The association must in no way savour of the nature of a trade ring or of a trust. Its general constitution, embracing all sections of the industry in all parts of the country, ensures this.

I am in full sympathy with any movement that is going to improve the present position of the electrical industry, and will always be pleased to give my cordial support to such efforts.

I would suggest for your consideration that it would be well to give the organisation a name which is calculated to express its objects, and the title I suggest is "The Electrical Industrial Association of Great Britain."

With a strong and active council representing all the various sections of the industry, and with the support of the existing institutions, I am sure that we will recover confidence and secure success.



We understand that the above suggestion is supported by the provisional committee of the "Electrical League," to whose propaganda we gave prominence in our issue of January 14th, p. 35, and that those who have already become members of the "Electrical League" will be asked to transfer their membership to the new association.

A RENEWABLE LINK FOR CHAIN-GRATE STOKERS

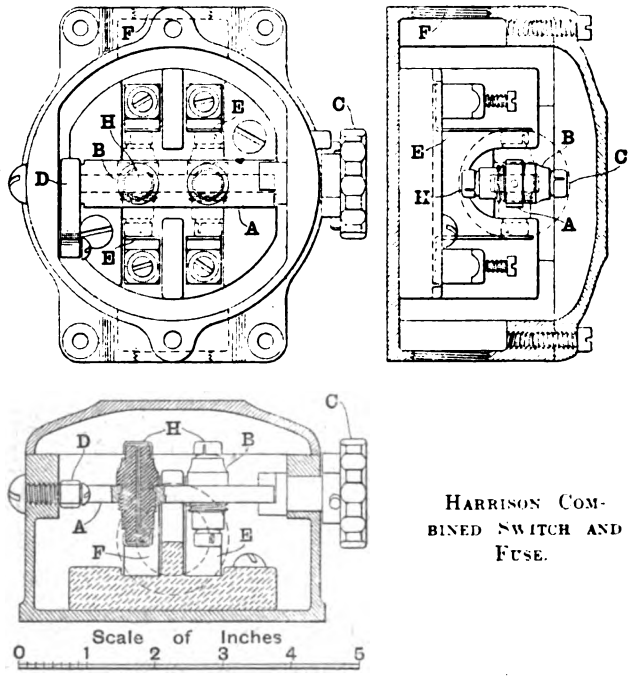
By C. G. M. B.

THE chain-grate stoker is now becoming very popular in central stations and elsewhere owing to the low-grade class of fuel which can be burnt upon it; but, like all mechanical apparatus, however well made, has a few weak points. It is only after lessons taught by experience that these weak points can be eliminated, or their weakness made less dangerous to the safe and continuous working of the apparatus. The special weakness we have in mind with regard to chain-grate stokers is the oft-occurring breakage of some of the links forming the continuous chain. A broken link expresses an element of danger, and may, sometimes, mean the putting out of action the grate upon which the breakage occurs. There is always a great possibility of considerable damage being brought about by a thus damaged portion of the chain fouling the rollers which support it, and in nine cases out of ten the failure of a chain-grate stoker is caused by a broken link which has been allowed to travel round and round until it jambs, regardless of the fact that the safety-clutch has given warning that things are not right. We are aware that in most cases the only alternative to throwing the grate out of operation (which, in nearly all cases, is undesirable) is the cutting out of the broken link. Here, again, there is a difficulty, for the open space so formed allows the coal fed on to the chain at this point to fall through, as well as allowing an excess of air to enter the furnace. This waste of fuel and admission of cold air continues as long as this space remains in the grate chain, and, consequently, the economy with which the plant can be worked is detracted from, while the unconsumed fuel or pieces of clinker which drop on to the lower band of the chain are likely to cause the grate to jamb, and thereby break more links.

Hitherto, the putting in of a new link meant the shutting down of the boiler, the withdrawal of the chain-grate, and the taking out of the bars or rods upon which the broken link had been threaded. This, of course, meant an expensive matter and loss of plant, all for the sake of a link the value of which perhaps

RENEWABLE LINK FOR CHAIN-GRATE STOKERS.

does not much exceed sixpence. The risk of leaving in a broken link also required some consideration, as further damage of some considerable extent might be caused by it. This weakness existing in chain-grate stokers has been dealt with by the invention of an interchangeable link, and the inventors, although not entirely eliminating the weakness, have reduced its danger to some marked degree. Links will still con-



Digitized by Google

tinue to break under ordinary working conditions, either from overheating, defective metal, or from ordinary wear and tear to which they are subjected while travelling through the furnace. This damage can now be immediately dealt with by a rapid repair, and a chain-grate stoker has no longer to be left with a gap in the chain and its latent danger for want of a means to replace a link.

The renewable link shown in the accompanying illustration is the invention of Messrs. Miller and Bennett, who were the original inventors of the close-link chain-grate stoker, and enables an unskilled attendant to replace a damaged link in a few seconds, and often without stopping the motion of the grate. This renewable link is left in position until such time as it is convenient to cool down the furnace and withdraw the stoker in order to put in an ordinary link. The renewable link is then taken out, and is fit for use again when occasion arises. If desired, the renewable links can be left in until they in their turn are damaged. The type of renewable link illustrated is provided with specially constructed slotted ends, which can be pressed into engagement with the metal rods upon which the links are threaded, the operation taking less than a minute to perform. There are alternative types of links for the above purpose, but the one illustrated is preferred for use in connection with chain-grate stokers.

NEW PATTERN OF SWITCH-FUSE BOX

A NEW pattern of switch-fuse box designed by Mr. Haydn Harrison, of 11 Victoria Street, Westminster, London, S.W., has been put on the market. The construction is illustrated by the accompanying figures, which represent a 10 amp. D.P. switch-fuse in plan and section. In all these figures, the switch is shown in the "off" position, but the "on" position is shown dotted. The two ebonite fuse carriers *B* are screwed into a brass turn-bar *A*, which can be given a quarter of a turn by means of the handle *C*, and the heads of the fuse carriers form the moving contacts of the switch. The loose notched handle

HARRISON COMBINED SWITCH AND FUSE.

opens the switch at the end of the quarter-turn, and a quick break at this point is obtained by means of a V-shaped spring *D*, which also prevents the switch from being left on in an intermediate position. The four brass contact-strips *E* are fixed together with the corresponding four terminals on to the porcelain base, and the porcelain insulating pieces between the terminals are moulded in one piece with the base. In the standard pattern, the whole switch is enclosed in a water-tight cast-iron case, provided with a machined cover, and the holes, indicated at *F* in the figures, can be obtained tapped to take any size tube. Boxes with sealing chambers for the incoming cables are also supplied.

The original form of fuse carrier used by Mr. Harrison in this type of switch was a cartridge fuse held by clips to the turn-bar. Later, an ebonite plug with screw terminals at each end and a fuse channel to one side of the centre was tried, but this construction left only a small thickness of insulation between the fuse and the brass turn-bar. In the latest pattern, shown in section in one of the figures, the fuse channel is in the centre of the ebonite plug, and the screw terminals are replaced by simple brass caps *H*, which fit tight over the ends of the plug. These caps are pressed on hard when the switch is closed, and we understand that tests have shown that there is no appreciable heating at the contacts even after several hours' running at 10 amperes. The caps are also easier to handle than the terminals when replacing a burnt-out fuse. This can be done by unscrewing the carrier from the turn-bar when the switch is in the off position without any possibility of shock, and either refusing the carrier or putting in a spare one. It will be noticed that a divided break is obtained, and we are informed that a switch of this pattern has been in use for some time on a 440 volt circuit with a motor taking 17 amperes.

The switch is particularly adapted to street lighting, and for this purpose it is operated by a key instead of a handle. It is interesting to note that each of the 2,000 lamp standards in Marylebone, for the conversion to electric lighting of which Mr. Harrison has received the contract, will be fitted with one of these switches. For house services, the use of this box should considerably cheapen the cost of connection, as the net cost of the box is about 8s., and further economy is obtained in erection owing to the straight run-through of the cables.

Manchester Cable Explosion.—At a meeting of the Electricity Committee of the Manchester Corporation held last week, it was agreed that the work of doing away with the old form of jointing between service and distributing cables, which is supposed to have been the cause of the explosion reported on page 547 of our last week's issue, must be pushed forward with all possible speed. It is expected that the work will be complete before the end of the year.

Electric Lighting and Fire Risks.—At the Fire Brigade Officers' Congress held at Westminster on Thursday last, a Paper was read by Mr. A. Pordage, Firemaster in Edinburgh, on the above subject. He expressed the opinion that the majority of "electrical" fires were caused by the fusion of gas pipes through contact with live conduit or other metal work. The conduit system, however, was, he said, a perfect method of distribution if the tubing was well earthed. In his experience only 2 per cent. of fires caused by defective circuits had been due to faults in wooden casing, and he advocated the use of wooden casing, particularly as the cables were preserved better in wood. The total number of "electrical" fires in Edinburgh during the past three years was 46. Of these 35 were due to contact between live tubing and gas pipes, 5 to faulty flexible wires, and 6 to miscellaneous causes. The Fire Service strongly supported electric lighting, however, as against gas lighting; it was only necessary to ensure that houses were properly wired.

Devonport Corporation and the Tramways Co.—As we reported in our columns at the time, the Devonport and District Tramways Co. recently decided to suspend their service of cars upon certain lines in Devonport, which they leased from the Corporation, for the reason that the traffic upon them was insufficient to render their working remunerative. The Corporation thereupon issued summonses against the company in respect of the matter, but the company applied to the High Courts for a rule *nisi*, preventing the summonses being proceeded with on the ground that the matter in dispute came within the arbitration clause of the Company's Acts, and therefore was not one for the summary jurisdiction of local magistrates. The question was discussed at length in the Divisional Court last week, before Lords Justice Jelf and A. T. Lawrence. For the company Mr. J. A. Simon, K.C., and Mr. Lynden Macassey appeared, and Mr. Danckwerts, K.C., and Mr. Courthorpe Munro appeared for the Corporation. The case put before the Court was that the Company covenanted by a lease, and under their Acts to provide upon the tramways in question a reasonable service of cars, subject to a penalty of £2 per day if the Corporation did not think the service provided was reasonable. There was also a clause in the Acts providing for arbitration in the event of differences between the parties. The Corporation sued the company under the Summary Jurisdiction Act for recovery of the penalties, but the Tramway Company's case was that the penalties were not recoverable in this manner, and if recoverable at all, were recoverable as liquidated damages after arbitration proceedings had taken place. After hearing the arguments, the Court unanimously decided against the company, holding that the penalties were provided for in the lease, and that the arbitration clause occurred in the Act.

SERIOUS CHARGES AGAINST THE WEST HAM ELECTRICITY COMMITTEE

ON Tuesday and Wednesday last week Mr. H. R. Hooper resumed the Local Government Board inquiry into the application by the Corporation for sanction to borrow £51,600 for the purposes of the electrical undertaking. As reported at the time in our columns, the inquiry was originally commenced in July of last year, but was adjourned owing to the refusal of the Corporation officials to give particulars of certain specific contracts which were asked for by the Inspector and the opponents to the application. Something of a deadlock took place between the Corporation and the Local Government Board, in consequence of which it became necessary for the Corporation to obtain considerable overdrafts from their bankers, in order to enable them to carry on the undertaking.

In an endeavour to secure a continuation of the inquiry, the Corporation called in Mr. Arthur Wright, who examined the contracts which it was alleged had been made at prices below cost, to advise them as to their fairness or otherwise, but at the same time the Corporation maintained their refusal to divulge the price. Some months later revised estimates were placed before the Local Government Board, not as a consequence of the dispute between the Corporation and the Board, but owing to the fact that much of the work for which the loan was required had since been completed, and the actual cost known, thus enabling a reduction to be made in the amount applied for. At the same time, several new amounts were applied for owing to further works being necessary, thus maintaining the amount of the original application at £51,600.

Since then the Corporation decided to ask the authority of the Local Government Board for sanction to borrow a further sum of £23,000, and both these amounts were the subject of the resumed inquiry last week. As before, the chief opposition to the proposed loan came from the India Rubber, Gutta Percha & Telegraph Works Co., who are represented by Mr. Elvy Robb, whilst Mr. Tweedey-Smith now appears on behalf of the electrical contractors in the district. It may also be mentioned that legal proceedings are pending between the Silvertown Co. and the Corporation in regard to the legality of the bank overdrafts.

As was the case at the previous inquiry, the Corporation still maintains its determination not to make public any details with regard to the working of the undertaking or of specific contracts which, in the opinion of its legal advisers, will tend to prejudice future contracts, or in any way interfere with the working of the undertaking. The argument put before the Inspector on innumerable occasions throughout the proceedings was that any corporation or company carrying on a business of this character, and subject to the amount of investigation which both the Inspector and the opponents desired, would quickly find it impossible to maintain its undertaking. It was urged that the Corporation justified their position as to the financial soundness of the undertaking by showing a profit on last year's working of £3,553.

A point about which there was considerable controversy was the price of 0·37d. per unit at which one particular consumer is supplied. Both the Inspector and Mr. Elvy Robb were particularly desirous of having the exact details of how these costs were made up, but beyond stating that the coal costs were 0·20d. per unit, Mr. A. H. Seabrook, who was the Council's electrical engineer at the time the contract was entered into, and is now their consulting electrical engineer, absolutely refused to give any other figures.

The question of excess expenditure was also the cause of a good deal of discussion and suggestive comments by Mr. Elvy Robb. It appears that the capital expenditure up to March 31st, 1909, was £472,364 whereas the total amount sanctioned was £417,583, or an excess expenditure of £54,781. Of this amount the sum of £11,358 has been provided out of revenue, leaving a net excess of £43,423. The Inspector inquired as to how this overdraft had been met, but Mr. Morton, K.C., who appeared on behalf of the Corporation, stated that this was exactly the point the Corporation did not wish to go into. In dealing with this matter, Mr. Elvy Robb suggested that the sinking fund had been tampered with in order to meet this expenditure, an absolutely illegal proceeding, and one which the Local Government Board should not condone. If the borrowing of large sums of money in this manner was to be permitted, it would stultify the whole working of the Local Government Board.

A further point touched upon by Mr. Elvy Robb on behalf of the Silvertown Co. was that whereas the electrical undertaking at West Ham for some unknown reason only paid rates to the extent of £114 per annum, his clients, upon whose business the capital expenditure was equal to that of the West Ham electricity undertaking, had to pay in rates no less than £7,000, and that if the two undertakings were rated upon the same basis, the whole of the profits shown in the last accounts of the electricity department would be wiped out.

Another allegation against the department was that cable had been supplied to customers at prices very much below the wholesale prices charged by the actual manufacturers, and that in one case, Siemens cable had been invoiced at exceptionally low rates, when, in fact, the actual cable supplied was not manufactured by Messrs. Siemens Bros. at all. In support of this, Mr. J. S. Huddlestone, of Messrs. Siemens Bros. & Co., was called, and asserted that the cable in question was not made by his firm either in this country or in Germany.

The inquiry was then adjourned until July 5th.

Street Lighting at Southampton.—Mr. H. F. Street, Borough Electrical Engineer, Southampton, informs us that the Council last Wednesday accepted with acclamation the recommendation of the Highways and Lighting Committee that 430 gas standards should be replaced by electric (metal filament) lamps. We understand that considerable pleasure has been expressed regarding those lamps which have been already changed over.

Institution of Mining Electrical Engineers.—A meeting of this Institution will be held in the lecture theatre, North of England Institute of Mining and Mechanical Engineers, Newcastle-on-Tyne, on Saturday, June 26th, at 7 p.m., for nominating officers for that branch for representation on the General Committee, and considering a report of the progress of the institution up to the present.

The American Institute of Electrical Engineers.—The following officers have been elected for the ensuing year: President, Mr. Lewis B. Stillwell; Vice-Presidents, Messrs. John J. Carty, Paul M. Lincoln, and Paul Spencer; Managers, Messrs. A. W. Berresford, W. S. Murray, H. H. Norris, and S. D. Sprong; Treasurer, Mr. George A. Hamilton; Secretary, Mr. Ralph W. Pope. The annual convention is to be held from June 28th to July 1st at Frontenac, near New York.

Telephones in Uruguay.—The Uruguayan Government have presented a Bill to authorise the sum of $1,500,000 for the construction of a State telephone system. There are already two companies working telephone systems in Uruguay, and the present intention of the Government is to compete with these, and not to acquire them. Mr. A. R. Bennett has advised the Government. It is proposed to issue a loan for the amount mentioned, bearing interest at 5 per cent.

The Home Office Rules for Factories.—The new regulations for the generation, distribution, and use of electrical energy in premises under the Factory Act, which were issued by the Home Office in January last after a prolonged inquiry into the matter conducted by Mr. James Swinburne (see ELECTRICAL ENGINEERING, January 21st, page 51, and January 28th, page 83), will come into force on Thursday next, July 1st, except as regards installations completed before July 1st, 1908, in respect to which they will come into force on January 1st, 1910.

Repair of Tramway Track in Dublin.—A short time ago the Dublin Corporation issued a number of summonses against the Dublin United Tramways Co., in respect of the alleged unsatisfactory condition of the company's tramway track. The company, however, contended that this was not a matter to be dealt with by summary jurisdiction, but should be a subject of arbitration under their Tramway Acts. An application was thereupon made to the High Courts for a conditional rule of prohibition restraining the Corporation from proceeding with the summonses before the magistrates. The case was argued a short while ago, and judgment was delivered last week. Mr. Justice Johnson and Mr. Justice Wright have now come to the conclusion that the section dealing with arbitration in the Company's Acts in no way interferes with the summary jurisdiction of the magistrate conferred by other parts of the Act. The Tramways Co., the Court held, were bound to keep the tram lines in such a condition as not to be a nuisance or danger to the ordinary traffic of the streets. The Court therefore refused the order asked for.

Inductance and Resistance in Telephone Circuits.—A Paper on this subject was read by Dr. J. W. Nicholson, at a recent meeting of the Physical Society. A general formula for the effective inductance of a circuit consisting of two long parallel wires has been given by the author, and is suitable for cases in which the current distribution in either wire is greatly affected by the frequency of alternation. In the present paper certain important cases are examined in detail, and formulæ are obtained capable of immediate use. A calculation of the effective resistance is also made in each case. Attention has been mainly directed to that of the simple telephone circuit, in which the leads are not twisted round each other in order to annul the inductive effects of the earth and of neighbouring circuits. Throughout the investigation only iron and copper wires as the two extreme cases are considered. The large permeability of iron completely changes the character of the effect of frequency on its self-induction, as compared with other metals. To all metals greatly used in practice, except iron, the formulæ developed for copper wires may be applied with a nearly identical order of accuracy.

CATALOGUES AND PAMPHLETS, &c., RECEIVED

[READERS APPLYING TO ANY OF THE UNDER-MENTIONED FIRMS FOR COPIES OF THE CATALOGUES OR PAMPHLETS REFERRED TO ARE REQUESTED TO MENTION "ELECTRICAL ENGINEERING."]

MEASURING INSTRUMENTS.—A new supplement to the recently-issued instrument catalogue of Messrs. Siemens Brothers & Co., Ltd. (Caxton House, Westminster), introduces one or two new pieces of apparatus. One of them is a high-resistance sensitive moving coil instrument to be used as a multi-voltmeter with shunts. A similar instrument is also combined with a portable potentiometer, so that it can be easily checked against a standard cell. Some new standards of self and mutual induction have also been brought out, in which bobbins of marble impregnated by a special process are used. There is also a considerable range of photometric apparatus, including a portable collapsible photometer for incandescent lamps, with Siemens-Bunsen silver spot screen, photometric laboratory benches, and a portable street photometer outfit, with Lummer-Brodhun instrument. Another novelty is a standard outfit for adjusting and testing arc lamps. These are provided with all the necessary adjustments, instruments, and regulating resistances. The image of the arc, instead of being observed by coloured spectacles, is projected by means of a magnifying glass in the door of the arc lamp cell on to a horizontal surface through the medium of an angle mirror, so that the behaviour of all the lamps may be observed without strain to the eyes.

METAL FILAMENT LAMPS.—A special bulletin dealing with Osram lamps has been issued by the General Electric Co. (71 Queen Victoria Street), to call attention to the reductions in price and new sizes of these lamps. A view is also given of the recently completed large factory adjoining the Robertson Lamp Works at Hammersmith, where a large number of the Osram lamps for the British market are already made. The smallest 100-135 volt now made takes 17 watts, and gives about 16 c.p., the 25, 32, and 50-c.p. sizes being made as before for these voltages. The most important new lamp is the 40-watt, 32-c.p., 200–260-volt lamp. High candle-power lamps, low-voltage lamps, and special candle lamps are also listed.

ELECTRICAL SUPPLIES, &c.—Among recent publications of the General Electric Co. are a series of cards illustrating the well-known "Peel" main switches, iron-clad distribution fuse-boards, house service cut-outs, and cooking apparatus, including a new electric milk heater with china interior. A new pocket abridged catalogue of motor-car electrical accessories has also been issued.

ELECTRIC DRILLS, &c.—A new edition of the electric tool catalogue of the Consolidated Pneumatic Tool Co., Ltd. (Palace Chambers, Bridge Street, S.W.), contains, in addition to descriptions of a number of well-known forms of electric drills and other tools, details of one or two new pieces of apparatus, including a new self-contained pillar drill with three speeds, and a new design of electrically-driven coal and ore rotary boring machine, with split nut feed.

WIRING FITTINGS.—A leaflet from Messrs. C. Schniewindt (Neuenrade, Westphalia, Germany) describes a new form of dowel-pin for fixing insulators to wooden, plaster, and cement walls. The pin itself has a central passage which extends to about half its length, and then comes out at the side. After inserting the pin, a nail is passed through the insulator, and a washer, and then driven down the centre of the pin so that it bends sideways into the wall. Various other patterns of dowel-pins, clips for conduit tubes, and similar fittings are also listed.

STORAGE BATTERIES.—The Hart Accumulator Co. (Stratford, E.) have sent us a copy of an attractive coloured show card which they are issuing to the trade. A number of patterns of cell made by the company are illustrated thereon, and we are asked to state that applications should be accompanied by trade cards.

CABLES.—The Indestructible Cable Co. have just issued a booklet dealing with the advantages of their special system of insulation for wires and cables. The insulation consists of a jute covering, impregnated with a mixture of red lead, linseed oil, and other patented ingredients which give a protection, not only undamaged, but even improved by atmospheric or chemical influences. Exposure to air also causes an oxidising process by which the insulating coating forms so hard a crust that it is almost impossible to cut into it with a knife.

MOTOR-CAR ACCESSORIES.—A new edition has been issued by Messrs. Siemens Brothers & Co., Ltd. (Caxton House, Westminster) of their catalogue of electrical accessories for motor-cars. The contents deal with coils, batteries, sparking plugs, and other ignition apparatus, including Obach dry cells for ignition purposes. Instruments and charging boards are also included. The Siemens electric speed-indicator takes the form of a small alternator driven by the car, and a special voltmeter calibrated to read direct in miles per hour. A number of patterns of electric horn are also listed. The lighting apparatus includes switches, lamp-holders, accumulator hand-lamps, roof, side, and tail lamps, garage lamps, &c. Among other accessories are communicators for transmitting orders to the driver, a tell-tale for sounding an alarm bell when the tail lamp is extinguished, and special high- and low-tension wires.

CORRESPONDENCE

ELECTRICITY IN COAL MINES.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—With reference to your publication of the Paper given by Mr. Robert Nelson before the Mining Engineers, I beg leave to refer to the following points, viz. :—

It is stated that the usual method of making gas-tight joints in colliery switches is to insert rubber rings between the flanges, or a plain metal to metal contact is advocated, ensuring a gas-tight or explosion-proof box. This is not satisfactory, as whatever precautions are taken in this direction, a box of this description does not fulfil its conditions, because the gases enter the small orifices of the case, which together with the gas formed on rupture according to its density, are of such an explosive nature that an explosion occurs with immediate expanding effects, bursting the switch case, and destroying the object of its design. Accidents have demonstrated this, and theoretically as well as practically, it is impossible to ensure a gas-tight switch unless immersed, as in the case of the three-phase switch referred to. Further, I notice that no attention was directed to the method of connecting and the position of terminals. These two points, apart from others omitted, are equally important.

The Davy lamp principle is equally dangerous, as the permission of space not only lends itself to the entry of gases, but on rupture the high volition of the formed combination does not admit of cooling effects, and further permits an entry of dust, which in itself is equally destructive, as evidenced by the reports of official inspectors.

Regarding earthing of the neutral for a three-phase system, I do not think this method saves the condition of catastrophe referred to, even if reliable gear is installed, as although there is a saving or cheapening of the cost of insulation, &c., this is negatived by the increase of fatalities due to leakage.

Regarding the Merz Price protection which is advocated, and which is not novel, a simple arrangement of protection is equally effective, according to the system involved, and much more desirable than the insertion of pilot wires and additional links in switchgear, which destroys its own object. Further, the most essential protection is that should a short occur, the arc up to the setting of the protection is *not* sufficient in any case to cause explosion to its degree of liability, irrespective of comparisons.

I therefore fail to see the point of competence and reliability, especially as the simple arrangement has been so successful in many mines, and dangers averted.

Yours, &c.,

A. G. C., A.M.I.E.E.

Manchester.

June 14th, 1909.

Water-Power for Nitrate Works in Bavaria.—The Berliner Cyanid-Ges., which, in conjunction with the Munich and Berlin Industrial Banks and other concerns, has recently formed the Bayerischen Stickstoffwerke Akt. Ges. (Bavarian Nitrogen Works Co.), has obtained a concession for 70 years from the Bavarian Government to utilise a portion of the water power of the River Alz for generating electrical energy for the manufacture of artificial nitrates.

Proposed Tax on Electric Lamps in Germany.—The Verband deutscher Elektrotechniker is opposing the German Government's new proposal to tax illuminating apparatus. It is asserted that the charges are unevenly distributed, and that the increase in the cost of lighting will vary from 0·2 to 35 per cent., according to the means adopted. It is further stated that lamp and carbon factories export about 60 per cent. of their output, and that as this is not always done direct, the export trade will suffer. Instead of 20 million marks, the Verband calculates that the revenue from the tax will be 11 million marks. This includes the revenue from illuminating apparatus purchased by the various State departments, without which the sum would fall to 8·5 million marks. Although about 53 per cent. of the apparatus concerned is for gas lighting, it is calculated that this would bring in only 29 per cent. of the total revenue, the remaining 71 per cent. being taken from electrical apparatus.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published June 17th, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications. Names in italics indicate communicators of inventions from abroad.

9,090/08. **Apparatus for Impregnating Insulation.** J. F. SIMPSON and A. W. BROWN. A chamber for drying and impregnating the insulation of armatures, coils, &c., is described in this specification. The walls of the chamber are cast round heating pipes or coils, which are supplied with steam. Means for admitting the insulating varnish and for producing either vacuum or pressure in the chamber, are also provided. Eight claims, four figures.

11,183/08. **Circuit Breaker.** BERTRAM AND E. THOMAS. This is a double-pole circuit-breaker, especially adapted for remote control. The right- and left-hand brushes are placed symmetrically and are hinged on links which form a toggle. The solenoid is placed centrally above, and the core rises and forces the brushes outwards on either side against the fixed contacts, and slides them along the contacts after the toggle has reached its limiting angle. If the control current is cut off, the weight of the core causes the toggle to be broken and the switch to open. Overload and reverse-current attachments are also described. Four claims, seven figures.

11,336/08. **Electric Driving of Rolling Mills, &c.** ELECTRIC CONSTRUCTION CO., LTD., and W. BUCHANAN. This is a D.C. load-equalising system, comprising an auxiliary motor and a flywheel on the main motor. The auxiliary motor is driven from the mains, and is excited by the armature current of the main motor. In series with the shunt-winding of the latter is a spring-controlled rheostat, which is operated by a rack and pinion device from the shaft of the auxiliary motor. The torque of the auxiliary motor balances the pull of the spring when the average current required by the work is taken by the main motor. If the load increases, the torque of the auxiliary motor increases, and the shunt resistance of the main motor is decreased, so that it drops in speed, and energy is given out by the flywheel. On the other hand, if the load decreases, the pull of the spring overcomes the torque of the auxiliary motor, the main motor is sped up, and energy is stored in the flywheel. A weight-controlled rheostat is also described. Three claims, two figures.

11,345/08. **Parallel Running of D.C. Generators.** BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*). Each generator is provided with a Tirrill regulator to the main control magnet of which are added two additional coils. One coil is connected across a resistance in the main generator circuit, and the other across a resistance in the main station circuit. These coils act in opposition, and by suitably proportioning the resistances the load is kept equally divided amongst all the machines. One line resistance acts as the shunt for the "line" coils of all the regulators. With two machines in parallel, this resistance is made one-half that of each of the generator circuit resistances, and then, with equally divided load, the coils will balance. If one machine takes more than its share of the load, its regulator will decrease its voltage. The load can also be proportioned in any desired manner. Four claims, one figure.

11,871/08. **Commutators for Turbo-Generators.** C. A. PARSONS and A. H. LAW. The bars are held together by conical rings on the outside at each end of the commutator, insulation being placed between the rings and the bars. The rings are bolted to comparatively thin metal diaphragms on hubs keyed to the shaft, and held in position by nuts. As the diaphragms are flexible in the axial direction, the bars can expand without causing any relative axial sliding between the supporting members. Modifications of this method of supporting the commutator are described. Four claims, six figures.

13,671/08. **Primary Cell.** K. HEINTZ. This is a cell of the Bunsen type, with iron or zinc negative and a depolarising solution consisting of 30 per cent. sulphuric acid and 70 per cent. nitric acid. The nitric acid is gradually used up, but with only 2 per cent. nitric acid, the E.M.F. is 1·75 volts. The exciting solution is zinc or iron sulphate, according to the negative element used. A diaphragm of carbon is used in place of a porous pot and can, in some cases, form the positive element. Three claims.

17,170/08. **Fuse Holder.** W. WHITE. This fuse holder, which may be of porcelain or other suitable material, is constructed in two halves hinged together. Contact pieces are provided at both ends, both inside and outside. When closed, the ends of the fuse wire are clamped between the inside pieces, and the outside pieces make contact with the spring contacts of the base or fuse board. A fastener or clip for keeping the halves together is provided. Three claims, four figures.

Opposition to Grant of Patents

4,339/08. **Magneto-Generator.** T. WARDELL. Opposition has been entered to the grant of this patent, which is for a generator for ignition purposes. The armature is divided into two halves both electrically and magnetically, and the windings are connected in parallel or in series to a single insulated terminal. Either the windings or the pole pieces are displaced about 45° or less relatively to each other, so that a strong spark is insured over a considerable range of motion.

17,458/08. **Tungsten-Nickel Alloy.** SIEMENS & HALSKE AKT.-GES. Opposition has been entered to the grant of this patent, a full abstract of which appeared in ELECTRICAL ENGINEERING of April 29th, 1909, page 406. Tungsten powder is mixed with about 10 per cent. of nickel, and the product is pressed into rods, which are then heated.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Summaries of some of the more important of these patents will appear in our next issue.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: GARE [Manufacture of ebonite] 4,484/08.

Dynamos, Motors, and Transformers: BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*) [Control of A.-C. commutator motors] 6,963/08; ALLGEMEINE ELEKTRICITÄTS GES. [A.-C. commutator motor] 11,633/08; SIEMENS BROS. DYNAMO WORKS, ABLETT and CROWE [Reversible rolling mills] 18,575/08. AKT. GES. BROWN, BOVERI & CIE [Starting of polyphase motors] 20,827/08; ZUMSTEG [Coupling motors and dynamos] 23,800/08; ALEXANDERSON [A.-C. commutator motor] 28,189/08.

Electric Ignition: BERGMANN [Sparking-plug] 17,816/08; BICKERTON, ROBSON, and NATIONAL GAS ENGINE CO. [Ignition device for internal combustion engines] 18,621/08.

Incandescent Lamps: DIERMAN [Metal-filament lamp installations] 12,398/08; KUZEL [Metal-filament lamp] 25,044/08; REGNART [Candle lamps] 5,567/09; BERGMANN ELEKTRICITÄTS-WERKE AKT. GES. [Metal filament lamps] 9,265/09.

Instruments and Meters: HARTMANN-KEMPF. [Frequency meter of the resonance type] 11,870/08.

Switchgear, Fuses, and Fittings: BOULT (*Electrical Manufacturing Co.*) [Automatic cut-outs] 12,142/08; SIEMENS-SCHUCKERT-WERKE GES. [Resistance coils] 580/09.

Telephony and Telegraphy: COBB [Telephonic apparatus] 16,029/08; DE FOREST [Secrecy system for wireless communication] 20,638/08; HANSELL [Support for telephones] 1,081/09.

Traction: HARRIS [Automatic brake] 12,000/08; BUCKELL and MULLEY [Signalling] 15,868/08; MOUNTAIN & GIBSON, LTD., and PRINGLE [Check rails] 18,856/08; SYKES and COOKE [Signalling] 24,030/08; THRELFALL [Brake] 25,026/08; LANGE [Points and switches] 25,416/08; CAIN [Signals] 207/09; STENTON [Signalling] 11,018/09.

Miscellaneous: BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*) ["Asymmetric" electrolytic conductor] 12,257/08; TRIER [Portable electro-magnets] 16,597/08; SIEMENS BROS. DYNAMO WORKS, ABLETT, and CROWE [Reversible rolling mills] 18,575/08; BELL and PLETTS [Water heater] 22,598/08.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

AKT. GES. BROWN, BOVERI ET CIE [Speed regulation of electrically-driven ring spinning-frames] 22,349/08; FRÉNOT [Lamps] 7,073/09; ZUCKERFABRIK FRANKENTHAL [Motor starter] 12,258/09; HALL [Safety devices for telephone, telegraph, and other lines] 12,869/09.

Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

Arc Lamps: C. OLIVER [Flame arc lamp economiser and reflector] 5,046/03.

Dynamos, Motors, & Transformers: R. BELFIELD (*B. G. Lamme, Westinghouse Co., U.S.A.*) [Stator winding for polyphase motors] 5,064/98; F. HODGKINSON [Testing balance of flywheels and rotors] 17,235/00.

Electrometallurgy & Electrochemistry: A. MCDOUGALL [Arc furnace for production of nitric oxide] 4,643/99.

Instruments & Meters: W. T. DREW [Prepayment attachment for meters] 4,936/03.

Telephony & Telegraphy: MÉRAY-HORVÁTH [Perforated tape transmitting and receiving apparatus] 4,972/03; W. P. THOMPSON (*Ges. für Drahtlose Telegraphie*) [Electrolytic receiver for wireless telegraphy] 5,105/04.

Traction: J. CLARET and O. VUILLEUMIER [Surface contact traction system] 4,773/96; R. A. HADFIELD and P. B. BROWN [Renewable crossings and points] 4,983/03; D. M. DABOO [Electric signalling system] 5,064/04.

Miscellaneous: H. J. DOWSING [Lamp radiators] 5,118/04.

It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.*

SUMMARY

A meeting of the Institution of Mining Electrical Engineers was held last Saturday at Newcastle for the formation of a Local Section of the Institution, and a meeting for a similar purpose will be held in Glasgow next Saturday. (Page 598.)

WE publish a letter commenting upon a push-button electric lift system recently described in our columns. (Page 599.)

WE publish a portrait of Mr. W. W. Lackie, Chief Electrical Engineer to the Electricity Department of the Glasgow Corporation, who has been elected President for the Incorporated Municipal Electrical Association for the coming year. (Page 599.)

IN an article dealing with the protection of three-phase feeders, Mr. M. B. Field points out that when resistances are used in the neutral-earth connection to limit the earth current, they must be constructed to dissipate very large amounts of energy, and that when choking coils are employed there is considerable danger of resonance phenomena occurring. He proposes a method of protecting systems with unearthed neutrals, based on the fact that on an earth occurring on any one phase, the total capacity current of the cable network will return along the earthed core of the faulty cable. This causes the cable to have a resultant magnetic effect which is utilised to operate a relay and disconnect the cable without any rush of current. (Page 599.)

JUDGMENT has been given in an action brought by Messrs. John Musgrave & Sons, Ltd., against the Bradford Corporation to recover the balance of the price of a large slow-speed generating set. The tests were satisfactory, and 85 per cent. of the price was paid, but trouble was experienced during the guarantee period of 12 months, owing to the breaking of bolts at the coupling between the armature spider and the flywheel. The Corporation assumed the trouble to be due to deflection of the shaft, and put a new one in, for the cost of which they counter-claimed. The Judge found that as the Corporation engineer was not satisfied, the sum claimed by Messrs. Musgrave & Sons was not due; also that the latter were responsible for

Digitized by Google

the expense of inserting new bolts, but not for the cost of the new shaft, as the old one was not proved to be defective. (Page 601.)

WE conclude in this issue our report of the proceedings at the Incorporated Municipal Electrical Association meeting in Manchester last week. The discussion upon the metal filament lamp question was the occasion for the production of some exceedingly useful figures, both as to the cost of street lighting and the comparative costs and consumptions of gas and electricity in the case of the small householder. It will also afford a guide to estimating the initial loss of output due to the metal filament lamp. Experiences with regard to cable systems were interchanged in the discussion on Mr. Hollingsworth's Paper, and it was shown incidentally that the short life allowed to "direct in ground" systems by the Local Government Board inspectors is far below that shown by actual practice. Our report of the debate on steam turbines and condensing plant contains a mass of useful figures and data, as practically every speaker spoke from experience. (Pages 601-609.)

AT the annual general meeting of the Association, Mr. W. W. Lackie, Chief Electrical Engineer to the Glasgow Corporation, was elected President for 1910, when the annual convention will be held in Glasgow. The senior vice-president is Mr. J. Christie (Brighton), and the junior vice-president Mr. G. Wilkinson (Harrogate). The Council's report dealt with economic wiring, the Electric Lighting Acts (Amendment) Bill, municipal financial organisation and administration, and income tax and depreciation on electrical plant. Some discussion took place upon the wiring clause in the Electric Lighting Acts (Amendments) Bill, and a resolution was passed to the effect that Lord Avebury's amendment stipulating that such work shall only be carried on through a contractor, should be opposed in the Committee stage. If this step is unsuccessful, rather than lose the Bill altogether, which it is felt contains some very useful clauses dealing with other matters, Lord Avebury's amendment is to be accepted. Some discussion also took place upon the proposals of the Institute of Municipal Treasurers and Accountants with regard to financial administration and organisation. (Page 610.)

THE accounts of the Finchley Electricity Department show a deficit of £292 for the past year.—A deficit of £3,801 is shown by the Hastings electricity accounts.—A net surplus of £1,914 is shown by the accounts of the Fulham electricity undertaking.—An Electrical Trades and Contractors' Association is to be formed in Melbourne.—The accounts of the Newport (Mon.) electricity undertaking show a deficit of £1,469 for the past year.—The new electric power house of the Central Argentine Railway Co. is almost complete. (Page 612.)

CABLES are required at Acton; condensing plant at Pontypridd; accumulators at Wallasey; tramway trackwork at Manchester; sub-station equipment at Haslingden; and arc lamps and cables, &c., at Swansea. A Local Government Board inquiry has been held at Dublin (£100,700); and an application is to be made by the Richmond (Dublin) District Asylum for a loan of £3,800. (Page 613.)

THE report of the British Electric Traction Co. for 1908 shows a net profit of £166,119. The 5 per cent. and 4½ per cent. debenture interest is paid, but only 3 per cent. on the preference shares. The Electric Taxi-Cab Co. is to be wound up. At the annual meeting of the "Z" Electric Lamp Co., it was stated that the company last month sold the whole of their stock to the trade at satisfactory prices. At the annual meeting of Marconi's Wireless Telegraph Co., it was stated that orders in hand amount to £100,000. (Page 614.)

THE hearing of the action brought by the British Westinghouse Co. against Mr. G. Braulik for alleged infringement of the Bremer 1902 flame arc lamp patent was concluded on Monday, but Mr. Justice Joyce has reserved judgment. Mr. Braulik disputes the validity of the patent chiefly on the ground of anticipation, and cites patents taken out for converging carbon lamps by A. Graham and E. H. Crosby in 1882 and 1896 respectively. It is further asserted that there was no subject matter for Bremer's patent, as the principle of applying a floating adjustment of the carbons was old. Disconformity is also alleged. On the other side it is argued that there was no floating adjustment in the Graham and Crosby lamps, and that there was subject matter for Bremer's patent, as the principle, though old, had only been used previously in vertical carbon lamps. (Page 617.)

A SHORT article is given, describing a device for the indication of the direction of the current in an alternating circuit. (Page 619.)

AMONG recent Papers read before the Physical Society was one by Mr. C. C. Paterson on the agreement between the American, British, and French authorities as to a unit of candle power. (Page 619.)

UNDER ELECTROMETALLURGY and ELECTROCHEMISTRY are given reports of several Papers on Electrometallurgical Engineering, recently read before the Faraday Society. One of these, by Mr. E. R. Taylor, dealt generally with the possibilities of water power for the supply of electrical energy, and electric furnaces of various types were described in Papers by C. H. Keller and G. Gin. Several other Papers on electrochemical subjects are noticed. (Page 620.)

A HIGH-EFFICIENCY carbon filament lamp, in which the filament is enclosed in a tube filled with mercury vapour and nitrogen, has been put on the market in Germany. It is said that it is possible to run the filament at an efficiency of from 1·5 to 1·8 watts per Hefner candle, the life under these conditions being from 600 to 800 hours. (Page 621.)

WE publish some further particulars of the facilities which are being provided to British exhibitors at the Brussels International Exhibition, 1910, by the Royal Commission on International Exhibitions. (Page 621.)

AMONG the specifications published by the Patent Office on Thursday was one by W. Dierman for the insertion of substitutional carbon filaments in metal filament lamps intended for series running, in order to indicate a broken filament and maintain the circuit. Siemens Bros. Dynamo Works, C. A. Ablett, and H. Crowe have one for a system of driving reversible rolling mills, which consists in supplying the main motor from a variable voltage flywheel generator coupled to a steam turbine run at about 25 per cent. below its most economical speed. Automatic steam governing must be provided. A method of renewing the worn part of tramway check rails by bolting on strips of manganese steel is described in a specification by Mountain & Gibson and P. J. Pringle. Two other specifications concern the mounting of metal filaments, and Siemens-Schuckertwerke Ges. have one relating to the winding of fine wire resistance coils. Silk threads are wound longitudinally with the wire inside the insulating covering to prevent the wire breaking. In spite of opposition, two patents for a process of making tungsten filaments have been granted to F. J. Planchon. Opposition has been entered to the grant of a patent to C. Notbohn and O. Estner for a heat accumulator for storing the heat from an intermittent supply of exhaust steam. (Page 622.)

Digitized by Google

THE enormous change that has taken place in the conditions of the electricity supply industry was emphasised by the Papers and discussions at the meeting of the Incorporated Municipal Electrical Association last week. Two factors have contributed to this change—the metal filament lamp and the steam turbine. The rapid success of the metal filament has exceeded all expectations on account of its extreme reliability, which, it must be confessed, was unexpected. With a new invention, especially one involving in its realisation so delicate an operation as producing and supporting a long metal wire whose diameter is in the order of one-thousandth of an inch, some initial difficulties in manufacture would, in the ordinary course, have been anticipated which would have made its introduction a more gradual one; but when the 100-volt and 200-volt Osram lamps appeared on the market they were, actually apart from the question of efficiency, a better lamp than the carbon filament which they have supplanted. With 17-watt lamps, the latest addition to the list of metal filament triumphs, giving double the candle-power of the 30-watt 8-c.p. carbon lamp, the days of the carbon filament are numbered, and as soon as we have a 200-volt 16-c.p. metal filament lamp as reliable as its predecessors, the carbon lamp may be considered obsolete.

This change, it is seen, has not been without its serious effect upon the output of electricity works, but the effect is only a prejudicial one for the moment. Even in the case of those supply authorities who cannot obtain a power load to make good the deficiency and at the same time to improve their load factor, there is still a fairly obvious means of turning the new condition of affairs to advantage. With the metal filament lamp, street-lighting by electricity is at once placed far in advance of gas lighting; this is well confirmed by the figures which we publish this week. There should soon not be a single town in the United Kingdom in which the side streets as well as the main streets are not electrically lighted. Moreover, it must not be forgotten that, even if the autput for street-lighting is no more in the first instance than that lost by the replacement of consumers' carbon lamps by metal filament lamps, the result will mean so enormous an improvement in the load factor that the change will be a profitable one. The lowness of the load factor is always caused by the private lighting peak, and the reduction of this peak by the use of more efficient lamps by the consumer is already an advantage partly compensating the loss in sales of units at peak load.

As regards the second alteration, which we have alluded to in the conditions governing electricity supply, a perusal of Mr. Blackman's Paper on steam turbines and the discussions upon it will show that, like the carbon lamp, the reciprocating engine is rapidly being ousted by a more efficient rival in central station practice. Like the metal filament lamp, the turbine at first only took the leading position in the case of large units, but now there is hardly an electricity supply undertaking in a town of moderate size in which the steam turbine does not recommend itself. The healthy competition between the reaction and impulse types keeps the rival makers well informed of any defects in either, and the high standard of efficiency and workmanship will be well contained in spite of tendencies to "cut" prices.

THE INSTITUTION OF MINING ELECTRICAL ENGINEERS

ON Saturday last a meeting was held in the Lecture Theatre of the Mining Institute at Newcastle-upon-Tyne in order to consider the advisability of forming a local section of the Institution. The gentlemen in attendance numbered twenty-eight, and included Mr. A. M. C. Field, the electrical engineer to the Consett Iron Co.; Mr. H. J. Fisher, of Fencehouses; Mr. Spence, of the General Electric Co.; Mr. H. W. Clothier, of Messrs. A. Reyrolle & Co.; and Mr. C. Anderson, of Messrs. Reid, Ferens & Co. Mr. Field, who was elected to the chair, introduced Mr. J. Williams, of Whitehaven, who outlined the objects of the Institution.

As the result of the local meetings it is proposed to form a general committee by September 4th, when rules will be formulated and the series of visits to collieries commenced. The Papers selected for reading by the "Paper Committee," elected by the general committee, will be available a week before reading, and an annual volume of transactions will be published, which will be strictly reserved to members. In addition to English members, proposals for membership have been received from the East Indies, Australia, and the Transvaal.

When the Institution is completely formed it is suggested that all subscriptions be paid into a central or head office fund, and a stipulated proportion allocated to local sections for expenses. At present expenses are drawn for each section from the general fund as required. The head office is at present located at Whitehaven, and local sections are being formed in the following districts:—Scotland (afterwards to be divided into two), Newcastle, Yorkshire, Lancashire, Derbyshire, Nottingham, Staffordshire, and Warwickshire, South of England, North Wales, South Wales, and Cumberland. In five of these districts meetings have already been held, and local officers appointed. There are up to the present just over 150 members, and in the Newcastle area twenty-eight proposals have been received. At the present time about 20 per cent. of these are consulting engineers or manufacturers of electric mining apparatus. As regards the question of recognition of the society, the formation of this Institution is being brought before the Conference of Colliery Managers. Two or three members of the Institution are colliery managers, and it is proposed to ask some of the general managers of collieries to take office. The question of recognition by and harmonious working with the Institution of Electrical Engineers was then discussed, and it was decided that the local committee be instructed by the meeting to notify the local section of the Institution of Electrical Engineers of the existence of the new Institution, and to see what arrangements could be made as to harmonious co-operation.

After the opinion, expressed by several colliery engineers present, that the status of the colliery electrician needed improving, and that support from colliery engineers would be forthcoming, the proposal to form a local section of the Institution was carried with one dissentient. The office of local President was left open, Messrs. Wraith, Field, Meikle, Alderson, Simpson, and Clothier were elected to serve as committee, and Mr. H. J. Fisher, of Burn House, Shiney Row, Fencehouses, who has been largely responsible for the local organisation of the Institution up to its present position, was elected secretary until the general meeting in September. It was then suggested that Wednesday evenings would be the most generally convenient time to hold meetings, and the meeting was closed with the customary vote of thanks.

A meeting is to be held in connection with the proposed formation of the Scottish section of the Institution on Saturday next, at 7 p.m., at the offices of the Institution of Engineers and Shipbuilders in Scotland, Elmbank Street, Glasgow, when local officers will be proposed and elected for the Scottish districts.

P. & O. Batti-Wallahs' Society.—The Summer Meeting of this society will be held on Saturday, July 17th, at Berkeley Cottage, Shillingford, Wallingford, Berks, at the invitation of the Vice-President and Mrs. F. B. Joseph. The train leaves Paddington Station at 10.40 a.m. Members requiring railway tickets at reduced fares should apply to J. F. Avila, 113 Charing Cross Road, London, W.C.

Long Distance Telephony.—Further successful experiments have been made with the new microphone invented by Messrs. C. E. Egner and J. G. Holmström, the former of whom is the chief engineer in the Stockholm telephone administration. Distances of 4,000 kilometres (2,500 miles) with 4·5 mm. copper wires, of 2,000 kilometres with 3 mm. copper wires, and of 400 kilometres with 4 mm. iron wire, have been negotiated.

It is stated that an agreement has been come to between the French and Spanish postal services for the establishment of four telephone lines between Paris and Madrid, Barcelona, and San Sebastian, and that France's share in the cost of the lines will be £24,000. It is said that these lines will be ready by Jan. 1st, 1910, and that through communication between London and Madrid *via* Paris, a distance of 1,100 miles, will be possible.

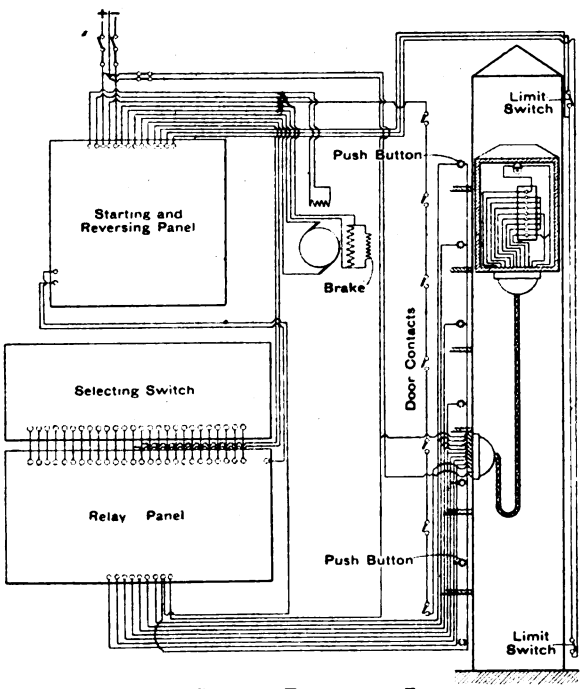
CORRESPONDENCE

PUSH BUTTON ELECTRIC LIFTS.

To the Editor of ELECTRICAL ENGINEERING.



SIR,—We noted with interest the article in your issue of June 10th, entitled "Push Button Electric Lift Control System." Simplicity is one of the merits claimed for the system described. Surely in view of the up-to-date control switch now

PUSH-BUTTON SERVICE LIFT FOR THREE OR MORE FLOORS.

upon the market in this country the claim cannot be substantiated.

We submit you a diagram of our own automatic (push-button) service and passenger lift controllers, the working parts of which are certainly very much less complicated than those of

PUSH-BUTTON PASSENGER LIFT.

the controller described in your article. The method described of inserting resistance in the circuit to prevent two relays lifting simultaneously is crude and inefficient, besides being an unnecessary complication.

With regard to the stopping device with separate switch at each floor, this is very similar to the Richmond-Carey patents which we hold; but we are no longer practising these patents, our present system marking a great advance upon anything which can be done with separate switches at each floor.

In your article it is claimed that with separate floor switches the stopping at floor levels with varying loads is more accurate; surely this is a mistake? Whichever system is used the switching off of the current is dependent upon the position of the car and not upon the load. The floor levelling can be adjusted upon the ordinary selecting switch to the greatest nicety. The real secret of good floor levelling with automatic push-button control lies in a soundly designed brake, and when high speeds are employed an efficient slowing down device.

Yours faithfully,
MARRYAT & PLACE.

28, Hatton Garden, London, E.C.,
June 24th, 1909.

The Iron and Steel Institute.—The autumn meeting of the Iron and Steel Institute will be held in London on Monday, Tuesday, Wednesday, and Thursday, September 27th, 28th 29th, 30th, and October 1st. The mornings of Tuesday and Wednesday will be devoted to the reading and discussion of papers at the Institution of Civil Engineers, and on the afternoons of Tuesday and Wednesday visits will be paid to works and to places of interest, including the Royal Arsenal, Woolwich; the works of Messrs. Siemens Bros., Woolwich; the generating station of the London County Council at Greenwich; the works of Messrs. Fraser & Chalmers, Ltd., Erith; the Lambeth Potteries of Messrs. Doulton & Co., Ltd., and the motor carriage works of Messrs. Napier & Son, Ltd., Acton. A visit will also be arranged to the Royal Small Arms Factory at Enfield, and to the National Physical Laboratory, Teddington. On Thursday afternoon the Lord Mayor and the Lady Mayoress have invited the members and their ladies to a reception at the Mansion House. The evening entertainments will consist of a theatrical performance on one night, and a banquet and musical entertainment on another night. In both these functions ladies can participate. There will also be visits to the Mint, to the Halls of several of the City Companies, and to the places of interest in the City. On Friday, October 1st, it is hoped to arrange an excursion to Portsmouth, and, by permission of the Admiralty, to visit any men-of-war which may be there on that day.

The Imperial Press Conference and Cable Rates.—Last Friday's meeting of the Imperial Press Conference was devoted to a discussion on "Cables Rates and Press Intercommunication," under the chairmanship of the Hon. H. L. W. Lawson. The committee appointed to consider the matter at the last Conference has done a good deal, and mainly as a result of their representations some substantial reductions in Press cable rates have been made. It was announced that the Pacific Cable Board had decided to reduce its charges for Press messages to one-half, and that the New Zealand Government would do the same in regard to their terminal charges. There was reason also to believe that the Government of the Commonwealth of Australia would do likewise. The committee are also urging reductions in the rates to India, Africa, and the West Indies. Mr. G. Marconi, in the course of a speech, intimated that his company would carry wireless Press messages across the Atlantic for 2½d. per word, and later, if the traffic increased, at 2d. per word. Several speakers advocated State-owned cables and lines to and across Canada, and resolutions were passed in favour of this course, both as regards Canada and South Africa.

Stamp Duty on Electric Supply Agreements.—In the Appeal Court last week judgment was given in the case in which the County of Durham Electrical Power Distribution Co., Ltd., appealed against a decision of the Commissioners of Inland Revenue in assessing a contract for electricity supply. The contract in question was with Messrs. Snowball, Son & Co., of Gateshead-on-Tyne, for a supply of electricity for seven years, there being a standing charge of £57 10s. per quarter, plus one penny per unit for all energy consumed, and ten shillings per quarter for meter hire. Such an agreement, the Commissioners of Inland Revenue declared, should be taxed with an *ad valorem* stamp duty of 2s. 6d. per £100, holding that it came within Schedule I. of the Stamp Act, and that it related to the sale of goods. On the other hand, Mr. Dankwerts, K.C., for the company, argued that the contract was, if anything, exempt from even a 6d. stamp, and that there was an express exemption from stamp duty in favour of such agreements. Mr. Justice Channell, from whose decision the appeal was made, whilst thinking that it was not the intention of the legislature that the Stamp Act should do what the Commissioners of Inland Revenue claimed, yet in fact it did do so, and he found for the Commissioners, a judgment which, he said, was against his own personal opinion. After hearing arguments, the Court dismissed the appeal, and upheld the judgment of Mr. Justice Channell. In connection with this case, we would refer our readers to some remarks made by Alderman G. Pearson, of Bristol, at the annual meeting of the Incorporated Municipal Electrical Association last week, which are reported on another page.

THE NEW I.M.E.A. PRESIDENT

MR. W. W. Lackie, Chief Engineer of the Electricity Department of the Glasgow Corporation, just elected President of the Incorporated Municipal Electrical Association, was born at Montrose in July, 1869. He was educated at Montrose Academy, Aberdeen Grammar School, and was two years at the engineering classes in University College, Dundee, under Professor Ewing. He afterwards attended Glasgow University, studying under Lord Kelvin. After leaving college, Mr. Lackie entered the services of Messrs. Mavor and Coulson, who then owned the concern which was later to develop into the Glasgow Corporation Electricity Department. When the Corporation took over the undertaking, Mr. Lackie transferred his services, and was made Mains Superintendent of the new Department. Having been promoted to be Chief Assistant Engineer, it was natural that Mr. Lackie should be appointed to the post of Chief when Mr. W. A. Chamen left Glasgow.

Since his appointment as Chief Engineer in 1905, Mr. Lackie has been President of the Scientific Society of the Glasgow Technical College for two sessions, and President of the Local Section of the Institution of Electrical Engineers, he is a Vice-President of the Institute of Engineers and Shipbuilders, and President of the Angus and Mearns Benevolent Society. To the Local Section of the Institution he has read several papers. The capital of the Glasgow Corporation Electricity Department's undertaking is close on £2,000,000, and the h.p. of the plant is about 50,000. There are 18,000 consumers connected to the mains.

Mr. Lackie's presidency commenced immediately after the annual general meeting and he will preside over the meetings of the Council during the year, concluding his term of office at the close of the 1910 Convention of the Association. This meeting, in accordance with the usual custom, will be held in the town of which the president is electrical engineer. Mr. Lackie is a good speaker, and will be a popular president.

PROTECTIVE DEVICE FOR THREE-PHASE FEEDERS

By M. B. Field

SOME engineers hold the opinion that in the event of a fault developing on one core of a feeder cable it is preferable to automatically cut off that feeder from the system immediately, and to this end they recommend earthing the neutral point. It has, moreover, been urged that earthing the neutral point limits the maximum potential difference between any part of the system and earth.

The neutral point may be connected to earth either directly or through a resistance. In the former case the resulting short-circuit when any core of a cable becomes earthed gives rise to an excessive current rush, and if the power of the generators behind the fault is great, the consequent jar or shock to the whole system may be accompanied by considerable and costly damage. A resistance between the neutral point and earth limits the current rush, but it must obviously be proportioned to pass sufficient current to trip any circuit breaker controlling a link of the network. Thus, if one feeder breaker be set to operate at 500 amps. and another at 20 amps., the current flowing in either case in the event of a core becoming earthed must be in excess of 500 amps. The energy absorption in the neutral point resistance when this current is flowing is obviously excessive. On a 6,500-volt system, the power developed in the neutral point resistance would be 3,750 volts × 500 amps., or, say, 1,775 kilowatts, and as it is necessary to guard against the somewhat improbable contingency of a circuit breaker failing to open, the resistance must be designed with a capacity for dissipating or absorbing such power for an appreciable time. For this reason, I have always advocated an open water resistance, which cannot be burned up and which can be proportioned to absorb a very large amount of power for a short period.

Choking coils have been proposed as more convenient than resistances in that they limit the current rush without involving energy absorption; but choking coils must be used for the purpose with the greatest discrimination. If we connect the neutral point to earth through a choking coil we have virtually an E.M.F., a self-induction, and a condenser included in a closed circuit. The self-induction is the choking coil connected between earth and the generator neutral point; while the dielectric of the cable system forms the condenser connected between the generator terminals and earth. In such a circuit, the conditions for resonance exist if the self-induction and capacity are so proportioned that the current flowing when the capacity is short-circuited equals that flowing when the self-induction is short-circuited. Suppose that the choking coil passes 500 amps. if one pole be put to earth, and that the normal capacity current per pole of the system at normal frequency and voltage is 18·5 amps. Consider what the effect would be with a triple frequency E.M.F. term. We may suppose that the amplitude of this term is b times that of the fundamental; thus, the current through the choking coil due to this harmonic (supposing the high-tension terminals of the generator to be earthed) would be $500/3 \times b$ $(=166{\cdot}6\,b)$; while the total capacity current to earth from all three poles together with the neutral point earthed, would be $(3 \times 18{\cdot}5) \times 3b$ $(=166{\cdot}5\,b)$—*i.e.*, resonance conditions.

While the capacity current assumed above is a large

D

Digitized by Google

figure, it is by no means an impossible one for some of the extensive systems in operation in this country. On the other hand, if we had assumed a capacity current of only 2 amperes per pole at normal frequency and voltage, we should similarly obtain resonance with respect to the eighth harmonic (or the term involving nine times the fundamental frequency). These examples will suffice to show that the use of choking coils for connecting the neutral point to earth is not altogether desirable since it may result in unduly increasing the potential difference between earth and the whole generator system and cable network. Such rises of potential will be alleviated in measure by combining a resistance with a choking coil, but if a resistance be introduced the question arises whether a choking coil be required at all.

The object of this communication is to put forward a suggestion for the protection of cables and so forth, with which the neutral point may either be unearthed or earthed through a relatively high resistance. Consider a generating station from which a number of high-tension three-core cables diverge, feeding separate (*i.e.*, not interconnected) areas. If there be no earthing on any particular feeder or on the network connected thereto, the sum total of the current in the three cores must be zero at every instant, and this is true independently of whether the load be balanced or not. If, then, the feeder cable be surrounded by the magnetic circuit of a ring-type transformer, there will be no total magnetisation in it. Now, although we assume that no point of the system is connected to earth, there will be a certain capacity current from each pole of the system to earth *via* the cable dielectric, &c., and it is clear that the total capacity current flowing to earth at any instant from any two poles, say, *A* and *B*, must equal the capacity current flowing from earth to the third pole, *C*, at that instant *via* the dielectric.

Suppose, now, there be an earth anywhere on pole *C* reducing this part of the system to ground potential. The capacity current to earth from *A* and *B* must find its return path through *C*; but since *C* is at zero potential, the current cannot be passing *via* the dielectric, and consequently the whole capacity current must pass from earth to pole *C via* the fault; in other words, if we had 20 healthy feeders and one faulty one with an earth on one core, the capacity current flowing to earth from the 20 healthy feeders would be restricted in its return path to the faulty one. Let us take it that the strength of this capacity current is 30 amps. Then, the induction in the magnetic circuit round the faulty cable will be due to 30 ampere-turns, and will be quite independent of the load on the feeder, while the induction in the transformer cores of the healthy feeders will be on the average due to 1·5 ampere-turns, the total capacity current being supposed to be equally divided among the 20 feeders. A ring-type transformer of the type referred to can readily be designed to operate a relay with 30 ampere-turns primary current or even less, and this relay may in turn operate an indicator, or alarm, or close the trip coil circuit of the circuit breaker. We should thus have a protective arrangement applicable to any extensive distribution with unearthed neutral, whereby any cable would be automatically disconnected should a core go to earth, and this without any rush of current and consequent disarrangement of the system.

We should arrive at the same result in a system of much smaller capacity by connecting the neutral point to earth through a relatively high resistance, viz., one capable of passing, say, only 30 amps. if a pole became earthed. There are many advantages in a high resistance of this order, besides that of cutting off the faulty feeder without excessive current rush. For example, the avoidance of interchange of current between generators working in parallel due to triple frequency terms in the E.M.F. wave; the relatively small size of the resistance required, &c. Complete protection would be afforded by current transformers inserted in any two of the phases with a ring-type transformer surrounding the whole.

There is one point in connection with the use of such ring-type transformers which must be guarded against, viz., individual action of the cable cores on the secondary winding. It is desired that the secondary be affected only by the magnetisation due to the total current passing through the cable, *i.e.*, the total current threading the magnetic circuit. The lines of magnetic induction due to this current will lie entirely within the iron circuit, and will be as *abcd* in Fig. 1. The secondary winding, however, must not be affected by any magnetic field due to the current in a *single* core. The path of the magnetic induction in this case does not lie wholly within the iron, and may be represented by the circuit *efgh* in Fig. 1. Seeing that the current in each cable core may be 100 times greater, or even more, than the current which we require to induce an E.M.F. in the secondary winding, the latter must

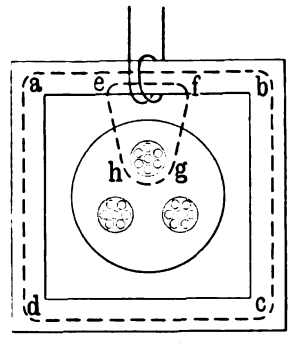

FIG. 1.

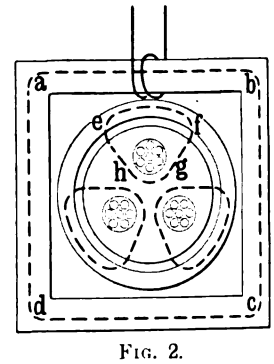

FIG. 2.

DIAGRAMS OF MAGNETIC CIRCUITS IN TRANSFORMER RELAY.

obviously be shielded from the individual action above referred to. This can be done in many ways, but perhaps the simplest is to surround the cable with an inner magnetic circuit, as in Fig. 2. It will be clear that the magnetisation due to the individual cores will be confined to the inner magnetic circuit; while the induction in the outer circuit will be due to the total current in the cable, and to that alone. I have designed a transformer on these lines about 18 in. long by 3 in. by 3 in., suitable for assembling around a cable in position, whether racked against a wall, or laid in a trench, without in any way cutting, disturbing, or otherwise injuring the cable. I find that while a total current of 20 amps. is sufficient to operate and release a circuit breaker, no individual action is noticeable, *i.e.*, so long as the sum total is zero, no secondary effect is produced, even though 500 or 600 amps. flow in each core of the cable.

Reference has been made to the fact that with the neutral point connected to earth the potential difference between any point of the system and earth is rendered more stable. This, however, is only partly correct, since if the neutral point be connected to earth through a resistance (whether high or low), and one pole be directly connected to earth through a fault, it is obvious that the potential of the rest of the system must rise in relation to earth in exactly the same way as if the neutral point were disconnected, unless, indeed, the current flowing to earth be so great as to materially drop the E.M.F. generated. I have also pointed out in a communication published in Vol. 41, No. 190 (1908, page 200) of the "Journal of the Institution of Electrical Engineers," entitled, "On the Potential of partially-insulated Systems in relation to the Potential of Earth," that when the neutral point is unearthed and the capacity of the whole system great, the system as regards its potential above earth is as stable as if the neutral point were connected to earth through a comparatively high resistance, the value of which depends on the amount of capacity current flowing between each pole and earth.

DISPUTE BETWEEN MESSRS. MUSGRAVE AND THE BRADFORD CORPORATION

JUDGMENT was given by Mr. Justice Darling on June 19th in an interesting action brought by Messrs. John Musgrave & Sons, Ltd., of Bolton, against the Bradford Corporation. The action was brought to recover the sum of £1,200 0s. 10d., the balance of the price of an engine supplied to the Corporation in March, 1905. The Corporation denied liability on the grounds that the engine did not fulfil the terms of the contract, and that payment was to be made only on the engineer's certificate, which had not been given. A counterclaim for £1,996, the cost of providing a new shaft, was also made. Mr. A. J. Walter, K.C., and Mr. W. J. Disturnal appeared for Messrs. Musgrave & Sons, and Sir A. Cripps, K.C., and Mr. C. C. Hutchinson for the Bradford Corporation.

The engine in question, which was christened the *Elsie* and is a duplicate of another engine, the *Maria*, previously supplied by Messrs. Musgrave & Sons to the Corporation, is a vertical, slow-speed, compound, condensing engine fitted with Corliss valve gear. It runs at 85 r.p.m., and is capable of developing 2,000 i.h.p. The armature of a Westinghouse generator is keyed on to the shaft between the cranks of the low- and high-pressure cylinders, and weighs 20 tons. The flywheel, which weighs 50 tons, is keyed to the shaft, and is also bolted to the armature spider. The shaft has a diameter of 23 in. at the centre, and 20 in. in the bearings. According to the contract, a trial run of four weeks was made, and this, the Corporation admits, was perfectly satisfactory. Messrs. Musgrave & Sons had agreed to make good any faults developed within twelve months of the completion of the contract. As regards payment, 85 per cent. of the total cost of £7,870 was to be paid on delivery, and the remaining 15 per cent. at the end of the twelve months providing the engine continued to work satisfactorily. It was this last amount which had not been paid.

It appears that on several occasions one or more of the bolts connecting the flywheel with the armature spider had broken. Mr. H. R. Burstall, who was called in by the Corporation to advise, had suggested that this was due to deflection of the shaft, and that it would be advisable to put in a larger one and of higher quality steel, if possible. He recommended running the engine with new bolts for the time being, however. These new bolts were supplied by Messrs. Musgrave. At the completion of the twelve months, the Corporation refused to pay the 15 per cent. retention money due, owing to the breaking of the bolts, and asked for a new shaft and for an extension of Messrs. Musgrave & Sons' liability for repairs. No arrangement was come to, and, a few months afterwards, the Corporation ordered a new and larger shaft from the Darlington Forge Co., the same firm which supplied the original shaft to Messrs. Musgrave & Sons. The counterclaim for £1,996 is for the expenses incurred in providing this new shaft.

Mr. Walter argued on behalf of Messrs. Musgrave & Sons that the engine had been submitted to undue strain, and produced evidence to the effect that it had been run continuously at an overload, and that the generator had on more than one occasion suffered a short-circuit. He also claimed that the certificate of the engineer was not a condition precedent to payment, but this Mr. Justice Darling did not agree with. With regard to the counterclaim, he contended that they were not liable for the cost of the new shaft, as the original one was found to be sound when taken out. In giving evidence, Mr. F. Musgrave, director of the company, stated that the shaft of the *Elsie* was the same as that of the *Maria*, with which no trouble had been experienced. He admitted that the Corporation engineer had not given his certificate. Mr. H. F. Parshall stated that after examining the engineer's diary, he had arrived at the conclusion that the cause of the bolts breaking was that the two surfaces of the coupling between the armature spider and the flywheel had not been properly brought together. If the machine had been indifferently assembled, as he thought it had, a short-circuit would have cracked the bolts. If the bolts had been taken out and the armature and flywheel held by the keys only, the set would, he thought, have run perfectly satisfactorily. The coupling was not necessary. Mr. A. S. Blackman, who was engineer to the Corporation at the time when the *Elsie* was installed, stated that the generator was shielded from the effects of a short-circuit on the system by an overload device, and that the engine had not been strained in this manner. He had not given his certificate because the *Elsie* had not given him complete satisfaction owing to the breaking of the bolts. He admitted that the bell-contacts he had arranged on the shaft to give warning of deflection had never operated. He denied that he had purposely overloaded the engine so as to ruin the shaft and compel Messrs. Musgrave & Sons to provide a larger shaft. He thought the breaking of the bolts was caused by the deflection of the shaft.

At this stage in the proceedings Mr. Justice Darling gave judgment on the claim. Mr. Blackman had, he thought, not been really satisfied with the engine, although he ought to have been, as the breaking of the bolts should not have convinced him that there was something wrong with the shaft. Mr. Blackman had withheld his certificate as a result of his own honest opinion, "Although," said the judge, "I think it was a wrong opinion. If he honestly believed what he did, although he wrongfully believed it, he did not wrongfully fail to certify." As the 15 per cent. retention money was only due on Mr. Blackman's certificate, and this certificate had been refused, judgment was given for the Corporation on the claim.

Sir Alfred Cripps, in opening the case for the counterclaim, asserted that a test on the steel used for the shaft in question showed that the elastic limit was only about half what it ought to be, and that Mr. Blackman was justified in his distrust of the shaft. Prof. J. O. Arnold, of Sheffield University, stated that from reports submitted to him, he was of the opinion that the shaft had been over-annealed, with the result that the elastic limit was too low. Mr. John Goodman, of Leeds University, upheld this view, but, being questioned by Mr. Walter, agreed that the bolts would break, as they did, all on one side if the flanges of the armature and flywheel were not true. Mr. H. R. Burstall was called to confirm his reports as to the reason of the breaking of the bolts, and then Mr. R. Yates, an engineer in the employ of Messrs. Musgrave & Sons, gave evidence to the effect that there had been trouble in fitting the armature, the flange being 4–1000ths of an inch out of truth at one point. Mr. T. Putnam, of the Darlington Forge Co., Mr. R. H. Stranger, steel specialist, Mr. Robert Hammond, and others gave evidence as to the good quality of the steel of the original shaft of the *Elsie*.

After counsel had made their final statements, Mr. Justice Darling gave judgment on the counterclaim, holding that the shaft had not been proved defective. In his opinion, the bolts broke because of the defective fitting of the flanges. Messrs. Musgrave & Sons should not, he said, have accepted the armature from the Westinghouse Co. with the flange not true, and were therefore responsible for the expenses incurred in fitting the new bolts, but not for the cost of the new shaft. He therefore gave judgment for the Corporation on the claim and on the counterclaim, with damages £10. The Corporation have the costs on both the claim and the counterclaim, except on the issue on which they failed, namely, the alleged defective workmanship of the shaft. A stay of execution for a month, with leave to appeal, was granted.

FOURTEENTH ANNUAL CONVENTION OF THE INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION

ON Wednesday last week, the second day of the meeting, the Association assembled at Liverpool, where they were welcomed by Sir Charles Petrie, Chairman of the Tramways and Electric Power and Lighting Committee of the Corporation.

INFLUENCE OF THE METAL FILAMENT LAMP ON THE ELECTRICAL INDUSTRY

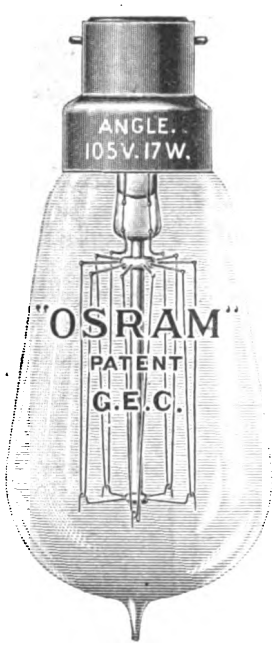
Mr. E. E. HOADLEY (Chief Electrical Engineer, Maidstone) read a Paper on this subject, in which he said that at present the A.C. stations have suffered most by the drop in output due to the higher efficiency of the new lamp, as the consumer can, by employing a transformer, have the same light as hitherto at a less consumption. The D.C. 200-volt stations will, Mr. Hoadley thinks, suffer in the near future, when lamps of smaller candle-power are available and the prices are reduced. He recommends them to push the heating and cooking business, if possible, with the aid of free wiring and hiring out heating and cooking apparatus if they can get powers. The latter part of the Paper dealt with the suitability of the new lamps for street lighting, and mentioned the author's experience that these lamps had an average life of 1,100 hours, individual lamps lasting from 5,000 to 6,000 hours. We published the Paper practically in full in our last issue.

Mr. S. E. FEDDEN (Chief Electrical Engineer, Sheffield), who opened the discussion, agreed with Mr. Hoadley that the metal filament lamp had given a considerable set-back to manufac-

Digitized by Google

turers of dynamos, engines, and boilers, but he thought that it would also affect the cable-makers, because it would have the effect of keeping the price of copper down, as in future it would not be necessary to lay down the same size mains for extensions, as was formerly the case. The reapers of the harvest were the lamp-makers. About a year ago one of the lamp manufacturers had distinctly told him that the total cost of a metal lamp was not more than 7d. The lamp-makers, however, were not the only people. The people who sold the lamps had also been making a good deal of money, owing to the large discounts allowed by the makers. He knew of one man who had started absolutely without any office and without any stores, who had been making £4 and £5 a week, simply by changing lamps. Having a single-phase station, he had felt the reduction of revenue considerably, it having been reduced by £4,000 last year. His own wiring department had changed over five thousand 200-volt; ten thousand 100-volt; four hundred and twenty 50-volt, and one hundred and forty-four 25-volt metal filament lamps, and it could be taken that there were about double that number in Sheffield. But this was a very small percentage of the 300.000 or 400,000 lamps connected, so that he had to be prepared for a very big reduction in revenue during the next year or two. This set-back, however, would show who had been the wise committees; that is, those who had put by sums from the available surplus for the rainy day, and had not acceded to the popular clamour and given everything to the rates. It had been said that people would increase the amount of illumination owing to the use of these new lamps, but he had not found it so. He knew that some of the chief clubs in Sheffield had reduced their bills by 64 per cent. To make up for each consumer whose lamps were changed, they ought to have three new ones, two to level up the revenue, and the third to help pay the interest and sinking-fund charges on the new services. The effect of all this was that some stations might have to go on the rates for a year or two. One good effect of the lamp, however, was that it was preventing customers from going back to gas. A great many had been saved in this way in Sheffield, and this effect would be still more increased in the near future, for he was quite of the opinion that there would be an enormous slump in the price of metallic lamps later on. There had been one on the Continent already. As a seller of these lamps himself, he would be exceedingly sorry to see a slump, although, as manager of an electric supply department, he hoped there would be a big slump. On the question of Corporations having power to do house wiring, which was touched upon in the Paper, the speaker said that the standard of wiring was considerably lower where the Corporation did not enter into competition with the contractors. Another reason for having their own department to do everything was that, of the 8.000 orders the wiring and fitting department of Sheffield carried out last year, 4,000 of them were little orders occurring after working hours, mostly during the night, and contractors could not afford to keep men on night duty. Further, if they had to give out all the work to contractors, there would be a ring formed and the prices would go up. He would like to speak a word of caution against hiring out stoves, ovens, &c., because of the rapid change taking place in the design of these things. A year or two ago he laid in a stock of £70 or £80 worth of all sorts of heating apparatus, but he had never been able to sell it, owing to the designs having changed so completely since the stock was laid in. He never would let out arc lamps on hire, but he did believe in hiring out motors, provided he could get back practically the complete price within three or four years. From the time he started hiring motors the price had gone down 60 or 70 per cent., so that if he had laid in a stock of motors, he would have been landed very badly.

Councillor A. H. DYKES (Beckenham) said that he represented one of those alternating-current stations which had been hit the hardest by the metal filament lamp After referring to the Paper which he had read in conjunction with Mr. Handcock before the Institution of Electrical Engineers some eighteen months ago (ELECTRICAL ENGINEERING, Vol. III., pp. 581 and 657), he explained what was being done now at Beckenham to meet the new conditions. Half their customers had been on a free wiring system, and before the metal filament lamp came these consumers generally used 8-c.p. lamps, and consumed on an average 15 units per annum per lamp installed. The receipts from the sale of current were 6s. 6d., and, adding wiring rent, meter charges, and so on, the total revenue per lamp was 8s. Last year they agreed to allow such consumers to have transformers and use 50-volt metal lamps, but insisted upon 16-c.p. lamps being used, and the sale of current had dropped from 6s. 6d. per lamp to 4s. The units consumed dropped from 15·6 to 9·8, but they had increased the wiring rental, with the result that the total revenue now was 6s. 4d. against 8s. Mr. Tapper, the Beckenham Council's Electrical Engineer, had gone to a lot of trouble to get at the cost of gas bills in Beckenham, and found that consumers of the same class as those referred to above were paying on an average 12s. per burner for gas, and a good many paid considerably over £1. Taking the case of a certain consumer who formerly had electric light but now had gas, his lamps consumed 5 c. ft. of gas per hour, and his consumption was about 7,500 c. ft. of gas per lamp per annum, and at 2s. 6d. (the price of gas at Beckenham) this amounted to 18s. 7d. per lamp per annum. Adding meter rent at 6d., this brought the total cost to 19s. 1d. A 30-watt 25-c.p. metal lamp would compare very fairly in point of light with the ordinary incandescent gas lamp mantle, and would have a consumption of 45 units per annum. At 5d. per unit (the price now charged at Beckenham) this would amount to 18s. 9d., and, adding 2s. for the rental of the wiring and transformer, and 9d. for meter rental, brought the total to 21s. 6d., thus making electricity only a little dearer. From his previous figures, however, for 500 hours' consumption instead of 1,500 hours, the total charge was only 6s. 4d., and they were not justified in charging a man 15s. 2d. more for the additional 30 units consumed in burning his lamps 1,000 hours longer during the year. These extra units only cost, in fact, a fraction of a 1d. Taking them at ½d., this would bring the receipts from the consumer to 7s. 7d. It might be argued that some allowance must be made for the man turning on several lights at once; for this particular class of consumer using 4, 5, and 6 lights there was very little risk of this, but in order to safeguard himself his proposed system was to charge 10s. per lamp per annum. The consumer would be deterred from wasting light, because he had to provide his own lamps. Even if he did waste light and turned on the lamps for twelve hours a day, the cost would still be less than 10s. Another way to deal with the matter in order to keep a check upon the size of the lamp installed, was for the electricity department to sell the lamps themselves through contractors, if necessary. This subsidiary profit would go a long way towards providing for the extra units that might be used wastefully. In Beckenham the cost of wiring and services had been 20s. per light for wiring and fittings, but this must come down if small consumers were to be supplied with cheaper units. He did not altogether like the idea of wiring spaced out from the wall, but pinned his faith to a form of concentric wiring. The Board of Trade now allowed the transformer to be installed for a whole terrace of houses, and by wiring with concentric it enabled a very considerable reduction in the cost of services. He thought that what would happen in the future with alternating-current stations would be that they would wire with high-tension mains everywhere under the street, and transform down from 2,000 or 3,000 volts by means of transformers for a whole terrace or block of houses, and wire with 100 volts or even 50 volts. He would even go a step further. He had now a proposal before the Board of Trade which had been passed by the Engineering Department. The Board of Trade at present provided that an insulation on the outer of the order of 5 megohms should be used. If the Board of Trade would allow them to earth all the way from a sub-station instead of earthing on the terrace or block of houses, this would considerably reduce the cost not only of interior wiring but also of mains.



Mr. HAYDN HARRISON said that in street lighting he had found that the cost of converting the lamp, &c., was a very small item compared with the cost of services. In a contract which he had in hand, the actual cost of changing the gas fittings to electrical fittings was under £1, but the cost of the services was over £2 15s. per connection. The difficulty was mostly with the labour. Another point which referred to street lighting and general lighting was the fact that metallic filament lamps were mostly large units of light, especially for the higher voltages, but this was an advantage to the supply authority, as, owing to the greater convenience of sub-dividing the lamps, a user of gas could be induced to put in two or three lamps in a room. Metal filament lamps had considerably improved the prospects of the street lighting engineer. In the old days it used to be necessary for him to go round with a photometer and demonstrate to the councillors the advantages of electric lighting over gas, but now he had only to take them out and they could see for themselves. He now dealt with the matter of persuading municipalities to adopt electricity for street lighting in a different manner altogether. In several cases the most successful results had been obtained by going to the electrical engineer first, and saying that he wanted a supply on a 40 per cent. load factor, between certain hours of the day throughout the year, and he had invariably been offered extremely low prices. He then went to the surveyor, and stated that if he would give a contract to do the street lighting under any terms or specification he liked, and any guarantees as regards efficiency of illumination, he, Mr. Harrison, would do it cheaper than the present cost of gas. They asked him why, and he told them by buying electricity from their own undertakings. The usual result was that he was told that if he could do it, the Corporation could do it themselves, and this was the reason why in several cases recently, municipal councils, in spite of being hampered on the question of loans, were now taking the street lighting from the gas people. Now that there was a comparatively small unit of light with metal filament lamps, it was worth while for engineers to consider the adoption of the series lighting system, which was very common in the United States. If they were laying new mains for street lighting they would find with series lighting that grouping 100-volt lamps in series of five or four at 440 volts was a very much more economical system as regards capital charges, both on mains, fittings, and everything else. Another advantage was

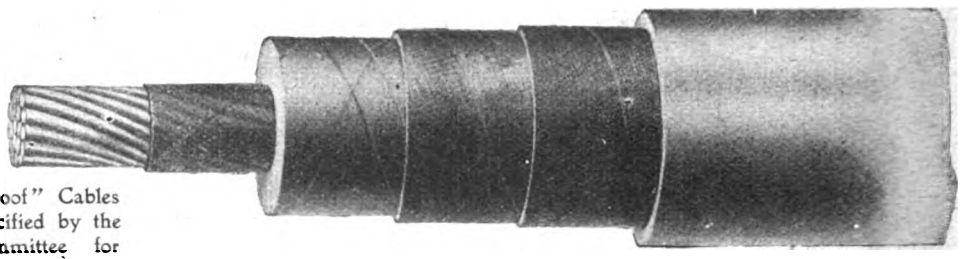
HELSBY CABLES

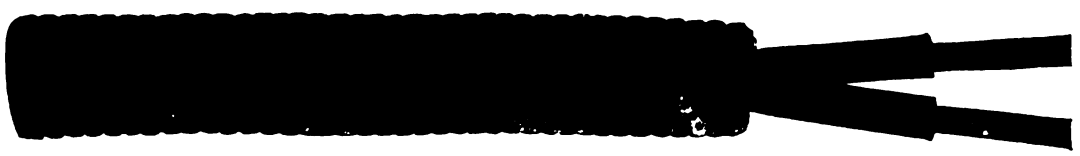


"OZONE-PROOF" CABLE

FOR HIGH VOLTAGES.

Insulated with Vulcanized Rubber. Either Braided or Lead-covered.

We guarantee our "Ozone-Proof" Cables to stand the pressure tests specified by the Engineering Standards Committee for double the specified period.



For further particulars see Pamphlet H 28.

HARD-CORD BRAIDED TRAILING CABLE

NON-METALLIC COVERING.

Specially designed for Durability and Flexibility.

Made at HELSBY by

BRITISH INSULATED & HELSBY CABLES LIMITED.

Head Office: PRESCOT, LANCASHIRE. Works: PRESCOT, HELSBY & LIVERPOOL.

Branch Offices: LONDON, MANCHESTER, GLASGOW, BIRMINGHAM, CARDIFF, NEWCASTLE, DUBLIN, & BELFAST.

The India-Rubber, Gutta-Percha and Telegraph Works Co., Ltd.

Manufacturers of:

Dynamos: Compound Wound, Shunt or Series, for Electric Light and Power.

Motors: Belt or Direct Drive, for all classes of Service.

Cables: Electric Light, Telegraph, Telephone, Submarine.

Wires: Insulated India-Rubber or Gutta-Percha, Cotton and Silk Covered.

PRICE LISTS ON APPLICATION.

that by a very simple contrivance which was now being tried by one or two engineers—it was not patented—they could be quite sure that if one lamp went out, the other lamp in the same post lit up in its place. No gas concern could do this with incandescent street lighting.

Mr. H. COLLINGS BISHOP (Chief Electrical Engineer, Newport, Mon.), thought that in spite of reduced revenue from ordinary consumers the metal filament lamp was to be thanked for a great deal in connection with street lighting. Some time ago, gas certainly held the sway for side street lighting, but this was now changed. He had found the life of Osram lamps for street lighting purposes much above what the manufacturers had first said it would be. Some of his lamps had run over 2,800 hours. He found they burned better and had a longer life on alternating-current circuits than on direct-current circuits. Further, the high-voltage type of lamp had a tendency to have a longer life than a low voltage. He also found the drop in candle-power far less, as with lamps burning in series there was always a tendency on the direct-current circuits for one of the lamps to blacken. This, however, he had overcome by periodically changing the lamps. He had found a very decreased life with lamps burning in series over those burning in parallel. During the past year 425 out of his 1,500 consumers had changed over to metal filament lamps, with the net reduction in their accounts of £1,380. On the other hand, he had found that metal filament lamps had introduced a large number of consumers, but these new consumers unfortunately only just enabled them to keep the revenue somewhere about the same figure it used to be, and as his capital charges were going up, the net results at the end of the year were worse. He thoroughly agreed with Mr. Fedden in advising caution in the matter of hiring apparatus. He had, however, been very successful in letting out arc lamps on hire, as upon the 400 or 500 lamps hired out, they were getting a return of over 20 per cent., and in addition the increased load.

COUNCILLOR DUDLEY STEWART (Wimbledon) said that the station at Wimbledon was a single-phase station, but was not obsolete, as Mr. Hoadley hinted all alternating-current stations were. He had been a great believer in metal filament lamps, because he thought they had popularised the industry more than anything else in recent years. At Wimbledon they had introduced 63-watt Osram lamps for street lighting, and there were 1,075 posts. When they first went into the matter they estimated on a life of 1,000 hours, but the results had been very surprising indeed. On four batches of lamps the following percentages only had failed in the first 1,000 hours, namely, 4·76 per cent., 6·45 per cent., 7·5 per cent., and 12·96 per cent.; and after 2,800 hours the percentages of burnt-out lamps were 43·75 per cent., 57·14 per cent., 57·4 per cent., and 63·44 per cent. A large number of lamps had already been burning for 3,000 hours, and the candle-power had kept up very well indeed, so that they expected to make considerably more saving than they originally anticipated. Figures had been taken out giving a comparison of five months' street lighting in 1908 and 1909 respectively. In the first month of 1908 (with 139 arc lamps and 1,034 32-c.p. carbon filament lamps) the number of units consumed was 83,810, and the similar figures for January this year (with 142 arc lamps and 1,052 63-watt Osram lamps) were 66,840 units. The total units consumed during the first five months of 1908 (with an average of 140·6 arc lamps and 1,040 32 c.p. carbon filament lamps) were 315,290, whilst for the same period in the present year the number of units consumed (using 142 arc lamps and an average of 1,054·5 63-watt Osrams during January and February, and 89 arc lamps, 39 330-watt Osrams, and 1,073 30-watt Osrams during March, April, and May) were 229,460, a decrease of 85,830. This represented a saving of 27·22 per cent. in the consumption during the five months. [The figures in brackets were kindly supplied to us subsequently by Mr. Stewart in order that we might make the comparison more definite.]

Mr. F SELLS (General Electric Co.), said he was not at all sure that the metal filament lamp had been a drawback even to the manufacturers of generating plant, because it had opened up an unexpected field for the manufacture of isolated plants; perhaps it was also just as well that large stations were not able to increase their plants at the present time, when the prices of electrical machinery were so very low. Metal filament lamps could not be produced at 7d., as suggested by Mr. Fedden, even in the large quantities turned out on the Continent. Even the price of 1s. 8d. was far off the limit, but when they were discussing this question in England, they must not forget the large sums that had had to be paid for patents and also for new factories. Considerable risks also had to be involved, and he thought it was only fair that when the price of these lamps was considered, they should take into consideration the same factors that they did when they talked about their own undertakings, and recommended that they should not part with every penny to the rates. Manufacturers, like municipalities, should be allowed to hoard up a certain amount for a rainy day. With regard to the candle-power and efficiency of these lamps, he had received at various times some very extraordinary letters. One central station man wanted to keep the candle-power and the price down; another wanted the price kept up but the candle-power reduced; other central-station men wanted both prices and candle-power reduced and kept up, because they were suppliers of electrical current on the one hand, and dealers in electric lamps, &c., on the other. With regard to street lighting, the hint thrown out by Mr. Hoadley concerning increasing the efficiencies in order to shorten the life of the lamps, need not frighten them, because he had been credibly informed that although the lamp makers had tried to shorten the life by giving a better efficiency, they could not do it.

Alderman SMITH (Liverpool), said from the Paper it appeared that the ratepayers upon whose credit municipal electrical undertakings had been obtained, were going to be called upon to dip their hands further into their pockets.

Mr. A. J. CRIDGE (Sheffield Corporation Meter Department) said that to raise the price of current to users of metal filament lamps was, in his opinion, contrary to the provisions of the Electric Lighting Acts. Referring to cheap wiring systems, he agreed that the Continental system was safe enough and good enough, but he doubted whether it was so cheap, as ordinary flexible cost 6d. per yard.

Councillor CROWTHER (Sheffield) expressed the opinion that municipal undertakings were as well or even better managed than many company undertakings. He disagreed with Alderman Smith, however, that the objects of such municipal electrical and other undertakings were to make large profits for the ratepayers.

Mr. E. HOADLEY replied briefly, reserving his full reply for the *Proceedings*.

MODERN CABLE SYSTEMS.

Mr. E. M. HOLLINGSWORTH (Chief Electrical Engineer, St. Helens, Lancs.), in a Paper which we published in a slightly condensed form in our last issue, reviewed generally the various methods of laying cables, noting from experience the technical details to be observed, and the dangers to be avoided. A description was also included of the overhead work and the subway at St. Helens, and a useful table was given showing the relative costs of the "direct in ground," "solid," and "draw in" systems.

Mr. W. W. LACKIE (Chief Electrical Engineer, Glasgow) said that the author advocated earthing metal-sheathed cables at many points, but personally he would prefer to earth at a limited number of points, so that the earthing could be disconnected for testing or other purposes. For low-tension continuous-current work he preferred leadless sheathing, and if this was run up solid in an earthenware trough, it gave a very considerable secondary insulation to the cable. They had had a very bitter experience in Glasgow with lead-covered cables run up solid in iron troughs, as frequently arcing took place between the lead and the iron when a fault occurred, but the arcing did not take place at the spot where the fault was. His standard practice now was to lay vulcanised bitumen cable in wooden troughs, run up solid with gas pitch. With regard to fusing, in the early days in Glasgow they had their network joined up solid throughout, but they had some very anxious times. They then tried joining all the network up through fuses, but the standard practice now was to run feeders from the station to a disconnecting box, and from this the network was fused, but each feeder had its own bit of network to supply, and these networks were not connected through. It was now no longer difficult to discover the position of a fault. Another advantage was that at the time of peak load in the winter it was possible to find out the load on each individual section of the network, which was of enormous importance to the mains department in balancing the system.

Mr. S. J. WATSON (Chief Electrical Engineer, Bury) said that of the £80,000,000 invested in the electrical industry, no less than £30,000,000 was in mains. He thought that the author's statement that he had to abandon his idea of defining present practice was something of a challenge to them. They had all been putting their heads together and endeavouring to standardise their buildings, boilers, and plant, yet at the same time there was no standard practice with regard to mains. He had always found it difficult to understand why, although they had made ample provision in their generating plants for accessibility to every detail, many of them laid their cables solid in the ground where they were absolutely un-get-at-able. He endorsed the opinion that vulcanised bitumen cable was very much better than lead-covered for direct-current, low-pressure supply. Vulcanised bitumen cables were not unreliable if one kept them clear of any ground in which there were likely to be acids; in one case he knew of this had been the cause of the bitumen absolutely disappearing off the cable. Another point in favour of vulcanised bitumen cables when drawn in was that there was practically never a very serious short circuit. In the case mentioned, there was a length of some 50 or 60 yards absolutely bare copper, and yet the total leakage was only of the order of 2 or 3 amperes. In his town he had installed about three-quarters of a mile of overhead mains. The cost of construction of a light line was only about 1s. per yard apart from the copper, and for a heavy line the cost was about 2s. compared with 5s. or 6s. for underground cables, and, in addition, they had only to put up bare copper instead of insulated copper. In the President's address the possibility of inter-connecting adja-

Digitized by Google

cent undertakings had been mentioned. Overhead mains should be used for this, and by installing them away from the main streets they could run them very cheaply, owing to the low cost of way-leaves.

Mr. F. A. NEWINGTON (Chief Electrical Engineer, Edinburgh) said that after trying all systems, he found in Edinburgh that lead-covered paper cables on the draw-in system suited the Edinburgh conditions best. He had found bitumen even more unreliable than rubber cable. As to paper, some makers advocated Manilla paper, whilst expert paper chemists argued that wood pulp was just as good. Then, again, there were impregnating oils that would last and others that would go rancid, and apparently they were entirely in the hands of the cable-makers. The author's costs for three single cables drawn in, compared with three laid solid, seemed to him to be very much too high.

Mr. W. A. VIGNOLES (Chief Electrical Engineer, Grimsby) said that in Grimsby practically all their troubles had been due to faults at the boxes. Their boxes were originally iron with a wiped joint made between the lead of the cable and the gun-metal glands screwed into the box. Considerable trouble had been experienced, however, from water getting into the box between the gun-metal glands and the box itself. He had recently designed a cast-iron box which was now being used in Grimsby with the lead cable wiped directly on to the cast-iron. There had been absolutely no trouble with these joints. He originally used triple concentric distributors, as any trouble would first develop on the outer of the cable, which was the earthed neutral, and it could be cleared before any harm was done. To save one jointing, however, he had now installed three-core cables through the smaller streets. The introduction of metal filament lamps would enable the size of distributors to be reduced. On his 230-volt three-wire system he was now using a three-core 0·02 sq. in. cable to supply a very large number of houses. The current per house of the smaller houses was, on the average, only about 2 amperes.

Mr. F. AYTON (Chief Electrical Engineer, Ipswich) had asked the cable-makers what cable they would recommend for cheap service connection. Their opinion differed very much indeed, but most favoured rubber, and he had adopted ordinary rubber lead-covered cable. For street lamp services he employed a box with enclosed fuses rated to blow at 30 amperes, and a 3/18 twin cable. He had had some experience of overhead mains in Ipswich, and in one place he had a 350-ft. span. There had been a little difficulty to get the Board of Trade to sanction such an enormous span, which had to go over the river Orwell, but finally the Board consented. It had never given any trouble since it was erected three years ago, although during the first winter he did not take the precaution of anchoring the cable down on to the insulators, but trusted to the weight of the cable.

Mr. J. E. EDGCOME (Chief Electrical Engineer, Kingston-on Thames) said that sixteen years ago armoured concentric cables laid direct in the ground were laid at Kingston-on-Thames. These were jute-insulated lead sheathed, and with jute between the lead sheathing and the armouring, and again over the armouring. There had only been four accidents on these during the sixteen years. A little while ago, owing to the operations of the tramway company, he had been obliged to move about seven or eight miles of feeders and distributors, and on taking them up found that the whitewash covering upon the cable when first laid still existed. The Local Government Board only allowed fifteen years for repayment against twenty years for cables laid on the solid system, but in his own case he had now been successful in getting the period increased to twenty years.

Mr. C. C. ATCHISON (Chief Electrical Engineer, Rochdale) said that in Rochdale paper and lead-armoured cables laid direct in the ground had been used from the commencement, and there had never been a single fault due to the cable itself. He thought it would be a very difficult thing to carry overhead the mains necessary to couple up the larger undertakings. When using aluminium for this purpose, they must take into account the extra size of the conductor in connection with wind pressure. In Rochdale, for developing the outside districts, he had utilised the tramway wires to connect power consumers in some instances.

Mr. S. E. FEDDEN (Chief Electrical Engineer, Sheffield) said that he had had bitumen cables laid on the solid system in the ground for sixteen years, and they had not cost a penny. Draw-in systems should not have any cable that would cause gas to form if a fault occurred, as these were likely to cause serious accidents. He would have absolutely no joint-boxes of any sort or kind on a lead-covered cable. He had the joints tagged with the name of the jointer, and had a book giving the exact location of every joint, and, in consequence, he had only had two joint faults in seven years. With regard to the cable itself, if they had pure Manila paper made preferably by an English firm, there would be no cable faults. He had 230 miles of lead-covered cable, and had not had a fault in eight years. He disagreed with the author that it was impossible to lay conduits through a street for any great distance and maintain a straight course. He thought this could be done if the pipes were laid with a bend in one direction only. In this way lengths up to 180 yards could be laid without the need for manholes. He did not believe in secondary insulation, as it tended towards the cable getting stuck in the conduits. This happened on one occasion in Sheffield, and he had only got the cable out by putting on a transformer and connecting the pipe to the secondary to warm.

Mr. HOLLINGSWORTH indicated his intention of replying in the *Proceedings*.

Visits to the Lister Drive station of the Liverpool Electricity Department and to the *Mauretania* were made in the afternoon.

On Thursday the Association met again in Manchester, and two Papers (which we give in condensed form below) were read in abstract and discussed simultaneously.

STEAM TURBINES.

FROM THE USERS' POINT OF VIEW.

By ALFRED S. BLACKMAN.

(*Borough Electrical Engineer and Manager, Sunderland.*)

BRIEFLY, the present situation of the steam-turbine industry is a battle for supremacy between the impulse and reaction types, and the following statements are put forward as representing the point of view of a user who has studied the problem from all sides :—

(1) *All turbines* must fulfil a certain law of combination of blade speed, and number of running rows.

(2) Steam expanding between boiler pressure and condenser, must generate a certain velocity, and this velocity must be imparted to the revolving mass in small increments as in the Parsons machine, entailing many rows of blades, or in larger increments as in the Zoelly or Curtis machines, or in one increment as in the Laval.

(3) The fewer the rows of running blades, the higher must be the speed at which the blades run, and consequently the higher the speed of the steam impinging on the blades.

(4) The impulse type turbine runs at a much higher speed at blading than the reaction type, and necessitates particular attention being given to the design of the wheels and blades, owing to the greater stresses that prevail.

(5) The impulse type turbine lends itself to a more mechanical looking construction than the reaction type.

(6) The reaction type, as illustrated by the best Parsons type, is more economical than the impulse type.

(7) For speeds of 3,000 revs. per minute and below 1,000 kw. the impulse type is better than the reaction.

(8) For speeds of 1,500 revs. per minute and up to 3,000 kw. the reaction type has, up to the present, proved most satisfactory.

(9) For speeds of 1,000 and 750 revs. per minute, and up to the largest sizes likely to be used, there is absolutely no evidence that the impulse type can compete in reliability or economy with the Parsons type.

A very important point which must be considered is that the reaction type has been longest in the field, the uses to which it has been put are of wider application, and the total horse-power in use must very greatly exceed that of the impulse type, and whether the impulse type will come through the many vicissitudes that are supposed to beset all turbines is a matter which has yet to be proved. A review of the progress of the last two years, the writer thinks, shows that, while trouble with the reaction type has shown a marked diminution (due to the defects of the earlier designs having had time to come to light, thus showing the necessity of more mechanical construction, and notably of stiffer shafts), the impulse type has not made the headway many people looked for, and may still be said to have its infantile complaints ahead.

After these preliminary remarks, which show the author's general leaning towards the reaction type of turbine, the Paper proceeded to recommend the adoption of higher speeds. Taking as an instance a 750-kw. 50-cycle machine, the author stated that the adoption of 3,000 r.p.m. with a 2-pole machine, instead of 1,500 r.p.m. with a 4-pole machine, would result in about 10 per cent. economy in steam consumption, 15 per cent. advantage in first cost, and would save floor space. The additional assistance to be obtained from external fan cooling of the generator, he added, should not be overlooked. At Sunderland there is a 1,500 r.p.m. Willans-Dick, Kerr combination, installed to carry a load of 2,000 kw. continuously, and 2,500 kw. for two hours. The economies effected by this plant have been exemplified by the fact that with the present normal works day load, amounting to about 2,300 kw. on the turbine, two boilers will easily steam the turbine, but upon changing over to three modern high speed reciprocating engines, of about 700 kw. capacity each, a third boiler is required. It is also necessary to hold additional boilers banked against the contingency of a failure of the turbine plant.

For D.C. sets, the author gave the following advantages for tandem machines :—(1) By putting in tandem generators, the speed of the set can be increased by about 75 per cent. with all the attendant advantages already pointed out. (2) The electrical portion being divided into two, there is only 50 per cent. of the machine out of commission should troubles of any sort arise.

The author had recently heard the remark of a well-known dynamo designer, that if direct current was wanted, the best

Digitized by Google

way of providing it was to put down turbo-alternators, and to use motor-generators for conversion to direct current; but he hoped that the serious commutation difficulties of a few years ago were being surmounted, and in this respect, he said, the radial brush gear of the Westinghouse Co. looked promising on paper.

The Paper next criticised the general statement, made frequently, that turbines should be used for units above 750 kw., and reciprocating engines below, and said that with the higher speeds at which it is now possible to run turbo-generators, "the proposition of turbines *versus* engines will soon disappear, and it will be a case of turbines only; in fact, it is even now difficult to prove a case for the reciprocating engine under any ordinary conditions." The Brush Company had informed him that a 300-kw. turbo-generator would consume 22 lbs. of dry steam per kw.-hour, or 19¾ lbs. of steam with 100° F. of superheat, as against 24 and 20½ respectively for a reciprocating engine, assuming 160 lbs. per sq. in. pressure in both cases, a 28-in. vacuum for the turbine and a 26-in. for the reciprocating engine. The capital cost complete with condensers was said to be practically the same in the two cases.

The author next recommended a steam pressure of only 150 lbs. per sq. in., because at higher pressures the volume becomes small and leakage percentages are increased, with only a small gain in B.Th.U.'s available. He also said that there is no appreciable gain in plant over-all economy with superheats above 150°.

With regard to the condensing plant, the author said: "A vacuum should be selected with an equivalent temperature about 25° above the available temperature of circulating water, and this gives a commercially obtainable and maintainable vacuum. If a vacuum of 28½ in. can be obtained, never let it drop to 27½ in., which it will easily do with a little inattention and neglect of glands, joints, sluice and automatic valves, &c., &c. An inch down in vacuum will mean a 5 per cent. rise in the coal bill. Work this out in expenditure per annum and it will draw its own moral. The writer has found a vacuum recorder kept under lock and key, worth considerably more than its weight in gold." He is of opinion that the field for improvement in condensing plant is even greater than in turbines, and considers that the Parson's augmentor is the best form of surface condensing plant.

Barometric condensers he regards as a very satisfactory form of plant, provided every precaution is taken to prevent air leakage, and ample passage-way given to steam and water. The power taken for pumping is slightly in excess of other types of condensing plant, but a great point is the uniformity of the vacuum which can be maintained owing to the absence of cooling surfaces, which become dirty and therefore inefficient. The author suggested that this type of condensing plant has been kept back, owing to the fact that when used with reciprocating engines, the presence of oil in the exhaust steam put difficulties in the way of using the hotwell water for boiler feed purposes. With turbines this difficulty has, of course, disappeared, and it is possible that barometric condensing plants will be more heard of in future; they are, he said, certainly more easy to maintain at their best than surface condensers.

Sunderland experience has shown the Willans-Parsons turbine to be absolutely trustworthy. For over sixteen months the bulk of the work has been done by the 2,000-kw. turbine plant of this make, running at 1,500 r.p.m., and during the year ending March 31st last, the total units generated in the works were 9,207,227, of which no less than 8,009,000, or 87 per cent. of the whole output, was generated by the one turbine plant. This turbine has, with very few exceptions, been put on load every Sunday at noon, and has run through without any stop until the following Sunday, to about 1 a.m. During the night the load drops, as a rule, to about 400 kw., and the day peaks have been about 2,300 kw.; when this has been exceeded, one or more 700 kw. reciprocating sets have been paralleled. Throughout the day the work has consisted of about three-quarters shipyard, and one-quarter tramway load, and it is of a very fluctuating character. During the whole of this time any sudden mishap to the turbine would have shut the whole system down, because in no case has there been sufficient plant in parallel with the turbine to take the load up temporarily, but in no instance has there been a hitch in any way attributable to the turbine: it runs through week after week with an entire absence of incident. After fairly lengthy experience of both high-speed piston valve, and slow-speed Corliss valve reciprocating engines, the writer trusts the turbine with equal confidence to either of these alternatives.

Mr. Blackman is of the opinion that maintenance costs on the steam turbine plant (consisting of turbine, alternator, and condensing plant), complete, should not exceed £100 per annum per 10,000,000 units generated. The maintenance of the Sunderland 2,000-kw. plant for the year ending March 31st last, including opening the turbine twice to measure clearances, came to less than £35. The Sunderland turbine exhausts into a barometric condenser. Wear upon the turbine itself appeared to have been negligible, and most careful examination had failed to reveal any signs of blade erosion.

The Paper next referred briefly to exhaust steam turbines. Many present-day condensing engine plants, with a good supply of cold water for circulating, could, the author said, be increased in output by 25 per cent. without any appreciable extra expense, save the capital cost of the exhaust turbine installation. Finally, Mr. Blackman stated that the 2,000-kw. Willans-Parsons set installed at Hylton Road, Sunderland, was tested on setting to work, and again on the expiration of one year and two months' work, during which time the plant had run over 9,000 hours, and generated over nine million units. The steam consumption on a 27½-in. vacuum was 17·07 lbs. of steam per unit on one test, and 17·1 lbs. of steam per unit on the other. As regards oil, which was logged separately from the other plant, the total cost for the year ending March last, was, for the turbine £13 8s., and for the turbine auxiliaries £18 8s. 6d., a total of £31 16s. 6d., equivalent to 0·000953 of a penny per unit generated.

NOTES ON CONDENSING AND WATER COOLING PLANTS.

By E. Lunn (Associate).*

(*Assistant Electrical Engineer, Corporation Electrical Supply Station, Huddersfield.*)

For steam turbines, condensing plant is essential, and it is usually advantageous in connection with reciprocating engines, but the load factor may in some cases be so low that, even with an unlimited supply of cold water conveniently situated, it would not pay to put in condensing plant. As a general rule, it is not worth while installing condensing plant unless the saving to be effected thereby will amount to more than 10 per cent. on the cost of such plant, as about that amount would be required to cover the cost of interest, depreciation, repairs, and attention.

Assuming a condensing plant would cost £3 per kw., and the cost of fuel and water to be 0·4d. per unit, and assuming that the plant effects a net saving in fuel and water of 16 per cent. (it is assumed that the steam consumption is reduced by 20 per cent., and that the steam required by the condensing plant amounts to 4 per cent.), then the saving in cost of fuel and water would equal 10 per cent. on the cost of the condensing plant (8 per cent. for interest and depreciation, and 2 per cent. for repairs), when the load factor amounted to 13 per cent. (*i.e.*, when 1,140 units were generated per kw. of plant per annum). By installing condensing plant, the maximum output of the engines would be increased by about 20 per cent., and in some cases this might be a valuable consideration, but neglecting the increased output of the engines and assuming the above data to be correct, there would be nothing to be gained by the installation of condensing plant, unless the load factor exceeded 10 per cent. where cheap condensing water was at hand, and 13 per cent. where cooling towers had to be used.

The ideal condenser, of course, is the one in which the condensing water attains the same temperature as the steam in the condenser, for the amount of condensing water is then reduced to a minimum, and the temperature of the water in the hotwell is the highest obtainable. The efficiency of a surface condenser is governed by the amount of heat transmitted per unit area of surface in a given time, from the exhaust steam to the water. The result of the heat having to be transmitted through metal surfaces, is that the temperature of the condensing water in an ordinary type surface condenser seldom approaches nearer than 15° Fahr. to that of the exhaust steam, approximately three times the difference obtained in a counter current jet condenser, in which no metal intervenes between the steam and water. When this subject was before the Association some years ago, it was stated that the possible theoretical gain from the absence of metal casing, between the hot steam and the cold water, would not work out at one-tenth of 1 per cent. Where the expense of obtaining condensing water necessitates the erection of a cooling tower, to the top of which the water will require to be lifted, the power required for this is appreciable. Consider the case of a condenser capable of creating a vacuum of 27 in. with condensing water at 80° Fahr. The temperature of steam at an absolute pressure equal to 27 in. vacuum is 114° Fahr., and the total heat of dry saturated steam at this temperature is equal to 1,116 B.Th.U. per lb. If the difference between the temperature of the exhaust steam and condensing water is 15° Fahr., the discharge temperature will be 99° Fahr. (*i.e.*, 114−15), and each lb. of water in passing through the condenser will receive an amount of heat equal to 99−80 equals 19 B.Th.U., therefore the amount of water necessary to condense 1 lb. of steam equals $\frac{1,116 - 99}{19}$ equals 53·5 lbs.

On the other hand, where a difference of only 5° Fahr. exists, which gives a discharge temperature of 109° Fahr. (*i.e.* 114−5), the heat received by each lb. of water equals 109−80 equals 29 B.Th.U., and the amount required to condense 1 lb. of steam equals $\frac{1,116 - 109}{29}$ equals 34·7 lbs., thus showing the amount of water in the former case to be 54 per cent. more than the amount required in the latter, and this is the ratio of the powers

* This paper, which we publish in abbreviated form, was submitted in competition for the I.M.E.A. Travelling Studentship, 1909, value £10 which has been awarded to the author.

Digitized by Google

required for the circulating pumps in the two cases. The higher the vacuum and the inlet temperature of condensing water, the more marked does this difference become.

In addition to the extra power required in the first case, the increased capacity of the cooling tower, pump, and pipes, means a corresponding increase in the capital expenditure.

The effective transmission of heat through the metal surfaces is adversely affected by the oil, held in suspension by the exhaust steam and deposited on the surface of the tubes during the process of condensation, and by the amount of air in contact with the tubes.

In an evaporative condenser the actual weight of water required to condense 1 lb. of steam is variously stated at from 0·75 to 10 lbs., and the power required by the air and circulating pumps is comparatively small. This type of condenser is unsuitable for high vacua, as the position of the condenser outside the engine-room necessitates a long line of exhaust pipe, and the number of joints where a leakage may occur is considerable. Corrosion of the pipes may be prevented to a large extent, by periodically passing a small quantity of oil over them.

A parallel flow jet condenser with wet air pump is a most inefficient type of condenser, as the steam comes at once into contact with the coldest water, and the bulk of the condensing takes place immediately, with the result that little further rise of temperature takes place as the water continues its way through the condenser. For a vacuum of 26 in. the power required by the pumps when dealing with 12,000 lbs. of steam is 50 per cent. more than with any other type, and for higher vacua the increase is considerably more. For small powers, and vacua not exceeding 26 in., the first cost is less than any other type of jet condenser.

The disadvantage of the low level counter current jet condenser is the remote possibility of flooding the condenser and exhaust pipe, due to the simultaneous failure of the float actuated throttle valve on the injection pipe, and of the emergency vacuum breaking valve. The author has, however, been in constant touch with a condenser working on these lines for the last two years, and has never known of the slightest trouble from this cause.

The amount of condensing water is less than in the surface type, due to the high temperature of the condensing water discharge, for equal vacua, the relative gain being greater the higher the temperature of the condensing water, and the higher the vacuum required. In discharging the water from a low-level jet condenser the pump has to work against a head measured by the vacuum. During a three hours' full-load test on a condenser of this type designed to condense 20,000 lbs. of steam per hour and maintain a vacuum of 26 in., an average temperature difference of 3·5° Fahr. between the exhaust steam and the discharge water was maintained without difficulty. The first cost of a plant of this size is from 70 to 80 per cent. of the cost of a barometric or surface type, the lower percentage where a cooling tower is required, and the higher percentage where water is obtained from a river or canal at a constant level.

A barometric counter-current jet condenser requires an expensive steel structure, and strong foundations for its support; the exhaust pipe is long, and the expense of erecting the plant is large. Against these disadvantages, however, must be set the advantage of the barometric action, derived from the elevated position of the condenser. Under no circumstances will the atmospheric pressure cause the water in the discharge pipe to rise so high as to reach the exhaust range. The only way in which water may reach the exhaust range, is when more water enters the condenser than the discharge pipe is capable of draining away. This may be brought about by a sudden increase in the speed of the pump when working at a high vacuum. If the area of the discharge pipe, and the height at which the exhaust pipe enters the condenser, are correct, the possibility of flooding the exhaust range is very remote. The plant is rather simpler in operation than the low-level type, and the power required to drive the pumps is practically the same in each case. The first cost of a plant of this type is practically the same as a surface type in the smaller sizes, but in the larger sizes the cost is considerably less. When comparing the horizontal and vertical types of counter-current jet condensers, the extra head of water required in the vertical arrangement must be taken into account.

An ejector condenser gives the best results when provided with an ample supply of cold water with a natural head, as it then becomes an exceedingly simple plant, requiring no moving parts in the form of air or circulating pumps. These conditions are seldom available, and in practically all cases a centrifugal pump must be provided, in order to obtain the necessary head of water. The author's experience of ejector condensers is that the injection water must be as free from air as possible, and that the best results obtain where the water is pumped into a tank, providing 15 to 20 ft. head at the injection inlet. This arrangement ensures a steady flow of water, and also allows any air to escape that may be carried forward by the water from leaky joints, or the bearings of the pump. Where a supply of water is obtained direct from a centrifugal pump, any air introduced in the above manner tends to break the column of water, and it is essential for the best working that the water be supplied in a constant unbroken column. The temperature of the water for an ejector condenser must be kept below 75° Fahr., as at temperatures above this the water and power become disproportionately high. As this type of plant works without an air pump it is not as suitable for high vacua as the surface and counter-current jet type, but it may be used with advantage in stations with a low load factor, as the cost is considerably less than any other type.

In providing motive power for the operation of air and circulating pumps in a central station, it is necessary to consider the question of continuity of operation, in addition to the efficiencies of the two methods of driving, as a failure of the vacuum may have serious consequences. The author contends that the possibilities of a failure occurring in the vacuum are less with steam than with electric driving. Steam-driven pumps, on the other hand, require from 50 to 100 per cent. more steam than electrically driven pumps, but this may be counterbalanced to a great extent, by the large percentage of the total heat of the steam it is possible to return to the boiler, by employing a feed water heater, even after allowing for the reduced efficiency of the economiser. Steam-driven pumps ought not to exhaust into the main condenser, for while a possible 10 per cent. reduction in the steam consumption of the pumps is effected, the reduction of the available capacity of the condenser, caused by this arrangement, is a more serious item.

The advent of the low-pressure exhaust steam turbine has increased the importance of the condensing plant, for with its aid it is possible in many cases to effect considerable economy, besides increasing the capacity, of practically any steam plant already in operation. There is as much available energy below the atmospheric pressure line as there is above, and the exhaust steam turbine is capable of utilising this lower pressure far more effectively than a reciprocating engine. The increased output obtainable by the installation of a plant of this type, together with condensing plant where not already installed, is from 25 to 100 per cent. of the present output. A 500-kw. exhaust steam turbine with steam pressure of 15 lbs. per square inch absolute, and 28-in. vacuum at turbine, will require 33 lbs. of steam per kw. at full load, and 40 lbs. at half load. In calculating the power available for a plant of this kind, an allowance must be made for the loss between engine exhaust and turbine admission.

For central station work the natural draught chimney type of cooling tower is the most common owing to the necessity of economy in ground space, and in order that the vapour issuing from the plant may be carried away at a height at which it will not become a nuisance to any inhabited buildings in the vicinity of the tower. The area of ground required is approximately 1 square foot for 20 lbs. of steam condensed (allowing 30 lbs. of water per lb. of steam), and the height varies from 40 to 80 ft.

The amount of water lost is usually found to be 75 per cent. of the water required for boiler feed, but, owing to varying climatic conditions, this quantity is not constant.

Where it is necessary to install plant of this nature, it is essential that the temperature of the water discharge from the condenser be as high as possible, conducive with economy in the condensing plant, as the conditions are then more favourable for the dispersion of the heat contained in the water. From this it will be plainly evident that surface condensers should only be used for high vacua when other considerations, such as boiler feed water, outweigh the factors of heat dispersion. For a high vacuum of, say, 28 in., and water leaving the condenser about 95° Fahr., the quantity of water required at 75° Fahr. would be only 75 per cent. of the quantity necessary when cooled to 80° Fahr., and as the cost of cooling plant would be practically the same in each case, the lower temperature is the more economical, as the saving in power would be considerable.

DISCUSSION.

Mr. BLACKMAN, at the close of the reading of his paper, said that having told them of the good working of the turbine, he would take them into his confidence and say that on the previous Wednesday week this turbine stripped. An increase of 10 lb. in the steam pressure was the only indication of anything having gone wrong, but the turbine ran for two or three hours and was shut down at 5 o'clock on the same afternoon. On opening up the case, the first ten rows of the blading were found to be stripped. No cessation of the supply was caused at all.

Mr. J. E. BOLAM (Borough Electrical Engineer, Weymouth) referred to a 300-kw. D.C. 460-volt Willans turbo-generator put down recently at Weymouth. On test, with 150 lb. steam pressure, no superheat, and 28 in. vacuum, the steam consumption was 21 lb. per kw.-hour at full load, 25 lb. at half-load, and 37 lb. at full load, non-condensing. Had superheat been used, say of 200° F., the full load figure would have been of the order of 17·6 lb. The generator gave no trouble when overloaded to an output of 420 kw., and there was no sparking at the brushes. When this load was thrown off and on, only a very slight "chut" was heard. The wear and maintenance of commutator and brushes had hitherto been a serious item, amounting in one station to 0·02d. per unit sold with old type machines. On the Weymouth machine, however, which had run every day from the beginning of November last, no appreciable wear was apparent on the commutator. At first, owing

Digitized by Google

to inexperience, the brushes were given too much tension, and they had to be trimmed weekly, but since Christmas it had been sufficient to trim and adjust them monthly. The brushes were of the affoliated type—four top and four bottom—with leading tips of carbon or morganite, each set covering four segments. At the present rate of wear, a set of brushes should last eighteen months; repairs and maintenance so far had been nil, and the economy such that one boiler was sufficient instead of two formerly used with reciprocating engines. On a load of 305 kw. a vacuum of 28·6 in. (barometer 30) was maintained on the turbo exhaust, with an expenditure of 1·6 kw. on the air-pump and 4 kw. on the circulating pump—a total of but 2·1 per cent. of the output. The capital cost, including condensing plant, was only £10 per kilowatt. In his opinion, the large reduction in capital cost amply compensated for the absence of any exceptional figures in running costs. Mr. Bolam concluded his remarks by relating some of his experiences with turbine plant at Bristol, at which electricity works he was formerly engaged.

Mr. D. B. MORISON (Richardsons, Westgarth & Co., Ltd.), referred to a remark in the President's address as to the tendency towards overlooking the business acumen of electrical engineers, but anyone who tried to sell them a turbine would very soon find out that the business acumen of electrical engineers was in parallel with their technical attainments. He thought reliability of the steam turbine could be accepted without question. The standard of workmanship of the Willans turbine was so high that the accident to the blading referred to by Mr. Blackman was undoubtedly a pure accident. His own firm had at present under construction a machine for Mr. Merz, of Newcastle, of 7,500 kw., or 9,000 kw. on overload.

PHOTOGRAPH SHOWING "ATOMISED" WATER.

Messrs. Brown, Boveri & Co., he believed, were contemplating the construction of a 15,000-kw. turbine, which would be the largest in the world. The popular size on the Continent, however, was about 10,000 kw. The Newcastle machine mentioned would have as its companion a machine by the Allgemeine Elektricitäts Gesellschaft of the same power, so that there would be an opportunity for very interesting comparisons. The speaker next alluded to the importance of preventing leakage of air into condensing systems, and referred to the utility of the air-gauge invented by Prof. Weighton, of the Armstrong College, Newcastle-upon-Tyne, which now enabled one to tell definitely in cubic feet per hour the leakage of air into any systems. He next referred to the Parsons vacuum augmentor, which, he said, was in fact a combination of steam jet and air pump. In calculating the horse-power of a reciprocating pump, however, they must not overlook the steam used by the augmentor. He had recently been making experiments with the object of doing away entirely with reciprocating air-pumps. M. Leblanc, of course, had set the pace in that direction with the Leblanc air-pump, which he believed was a very good apparatus. In his own experiments, however, he had combined a steam jet with a water jet, and the result was that, day in and day out, he got remarkable results. In order to show the influence of a steam jet as an air withdrawer, a short time ago he attached a steam jet to a closed pipe in which there was a socket filled with water, and in this was immersed an ordinary thermometer. By the aid of the steam jet the thermometer was frozen in the socket. He had come to the conclusion that the best pump for withdrawing hot water from condensers was a steam-driven single-cylinder reciprocating pump, and one of this type was now under test at Hartlepool. With regard to exhaust steam turbines, his firm now had under consideration a scheme in which three condensing blowing engines indicated between them 3,300 h.p., but they could absolutely guarantee a further 1,200 h.p. without any expenditure upon alterations to the present installation. The speaker also gave some examples of the application of these machines to modern marine engines. With regard to Mr. Lunn's Paper, the transfer of heat from a tube was not impeded by the tube itself. It was impeded, but only to a negligible extent, by the metal in the tube if the metal was clean—clean on the water side and free from air on the steam side. Mr. Lunn's figure of 152 as the difference in temperature between the steam and the circulating water discharge, was not representative of latest types of surface condenser; there was no reason why it should exceed from 5 to 8 degrees; in fact, Prof. Weighton at the Durham College of Science had carried out some experiments in which he had brought this down to 1°. Mr. Morrison then said that he had been struck by the clumsiness of the initial distribution of water in cooling towers, and had set himself to endeavour to atomise the water as quickly as possible. A rope of water 1¾ in. diameter was allowed to fall 20 feet on a platter, and the effect was shown in the photograph opposite. There was a diameter of about 6 ft., into which the water was so subdivided that it covered the enclosed area uniformly, and not merely the extreme periphery.

Mr. T. P. WILMSHURST (Chief Electrical Engineer, Derby) asked whether it was true that the makers of impulse turbines could not guarantee the efficiency for any considerable number of years, on account of the attrition of the blades due to the high velocity of the steam. He would also like to know what prospect there was of being able to get a direct-current generator of more than 1,000 kw. capacity, because he thought it was obvious that the efficiency of, say, a 2,000 kw. generator must be higher than two 1,000 kw. sets in tandem, to say nothing of the very large ground space occupied by the tandem set. Although he had six D.C. turbines, and some running on traction, he had never had a single case of flashing round the commutator during six years' use. He thoroughly endorsed the employment of the vacuum recorder, and also recommended the use of a steam temperature recorder in order to have a constant record of the superheat, because excessive superheat had a large influence on the question of stripping. He agreed that turbines did run with exceedingly low repair costs, but when an accident did happen, it was quite possible that it would be a very large one, and therefore the costs given in the Paper were too low to be accepted as an average over a number of years. Finally, he appealed to the makers, when large accidents did occur, to do all they could to assist the engineer liberally, although the period of maintenance might have expired. This would do much to remove the feeling which existed in certain quarters, that the turbines were not absolutely reliable.

Mr. J. P. GREGORY (British Thomson-Houston Co.) said that a great many turbines of the impulse type had been in service for years, and as far as he knew, there was no record of blade stripping. In reference to Mr. Blackman's statement that the impulse type had not made the headway many people looked for, he said that up to June 5th this year, 50,000 kw. of Curtis turbines were running in England, and 25,000 kw. were being manufactured at the present time in America. These machines were all over 1,000 kw. In America the General Electric Co. had turned out 1,172,000 kw. of these machines. Six were 14,000 kw.; eleven 9,000 kw.; twenty were 8,000 kw.; and 42 were 5,000 kw. In addition, many similar machines had been made by the A.E.G. and the French Thomson-Houston Co. On the question of efficiency, he said that a 1,000 kw. set at the South Lancashire Tramways station was tested by Prof. Wilson, of King's College, London. The steam pressure was 153 lbs., superheat 100° F., vacuum 28·88; and the steam consumption at full load was 15·8 lbs. per kw.-hour. Another machine of 2,500 kw. was recently sold to a colliery in South Wales, and on test, with steam pressure of 126 lbs., superheat 68° F., and 28·4 in. of vacuum, the steam consumption came out to 16·06 lbs. per kw.-hour at full load, and 18·67 lbs. at half load. Another machine of 9,000 kw. recently tested at Chicago, showed a steam consumption at full load of 12·9 lbs. per kw. hour, and the variation over the whole range of from 5,300 to 14,000 kw., was only about three-quarter lb. A Curtis turbine of 4,000 kw. by the A.E.G. tested with a steam pressure of 180 lbs., a superheat of 280° F., and a vacuum of 29·2, had a steam consumption at full load of 11·9 lbs. per kw.-hour, and half load, 11·7 lbs. [We understand that this was an official test, made only a few months ago by the Boiler Inspection Co. of Dortmund at the Rummelsberg electricity works near Berlin, and is not the much-spoken-of "Moabit" machine.] As to Mr. Blackman's statement that the impulse type of turbine did not lend itself so well to economical working in connection with exhaust steam as the reaction type, Mr. Gregory said that wet steam was surely detrimental to any type of turbine, whilst as to friction, the impulse type permitted large quantities of water to be passed through the turbine without injuring it, whereas with the reaction type, water was apt to create a good deal of trouble.

Mr. E. E. HOADLEY (Chief Electrical Engineer, Maidstone) asked one or two questions with regard to exhaust steam turbines.

Mr. G. SEATON (Willans & Robinson, Ltd.) said this was about the first time that contractors had been given the credit of being any good. When a new turbine was installed, what usually happened was this. In the first month, everybody was in a great funk, but after a month's running the load was then rapidly transferred from the reciprocating engines to the

Digitized by Google

turbines. In about twelve months' time, great prominence was given to the costs, and the whole of the credit was given to Mr. So-and-So's management. There were mills running in Lancashire to-day with both reaction and impulse turbines, and there was no doubt that from the coal consumption point of view, the reaction type was holding its own. In order to get the remarkable figures given for impulse turbines, it had always been necessary to have a high degree of superheat. Direct-fired superheaters were used, and his experience of these was that coal was burned in them at about 30 per cent. efficiency, instead of at about 70 per cent. efficiency in the boilers. Although the steam figures might be remarkably good, the coal figures were very bad. In conclusion, he thanked Mr. Morison for his graceful reference to the good workmanship of the Willans turbines.

Mr. W. B. WOODHOUSE (Yorkshire Electric Power Co.) said he had found the Curtis type of machine extremely reliable. The oil bill on two Curtis turbines was less than £5 per machine per annum. One of his Curtis turbines had been recently opened in order to decide the details of construction for a new machine, and after five years' running there was no sign of erosion. He regarded the exhaust steam turbines as an expedient which would disappear in a few years. If he did put in an exhaust steam turbine he would make it a mixed steam one, and prepare for the day when the reciprocating engine was abandoned altogether. Mr. Lunn had mentioned the length of the water path in a surface condenser as being of the order of 20 ft. He had taken out the temperature readings on a condenser in which the water path was 40 ft., the tubes being 10 ft. long, and the water passing four times. The increase of temperature in the water on the first pass was 8° F., on the second 6° F., on the third 5° F., and on the fourth 4° F. So it was apparent, at all events for that particular condenser, that a water path of 40 ft. in length was not too much. In attempting to improve the vacuum, a point that struck him as being worth following up, had been a consideration of the well-known effect that by putting the velocity of the water up to something above 7 ft. per second, a much better scrubbing action was obtained. This had been tried, and very much better transfers of heat from steam to water had been obtained. He had been trying something similar on the steam side, and suggested, although he believed it had been tried before, the spraying of the air-pump discharge, that is, the condensed steam in the bottom of the condenser, against the steam sides of the tubes.

Mr. F. A. NEWINGTON (Chief Electrical Engineer, Edinburgh) said that he had recently put down two exhaust steam turbines of 1,200 kw. driving continuous-current machines at 500 volts. They had live steam connections fitted in case an extra supply of steam was required. His exhaust turbine sets had not been running sufficiently long to give figures, but the makers guaranteed 1,200 kw. at 45,600 lbs. of steam per hour with a vacuum of 27¾ in., and he knew quite well that this output could easily be obtained. From actual working, the coal consumption compared with non-condensing reciprocating sets would be 15 per cent. better. He though there was likely to be some trouble with atmospheric valves on exhaust steam turbines. With high-pressure turbines, the atmospheric valves were running on vacuum, but with exhaust steam turbines the atmospheric valve between the reciprocating engine and the turbine was practically at atmospheric pressure, and was thus apt to vitrate and give trouble. At Edinburgh they had originally intended to use cooling towers, but it was thought that the steam issuing from the top would injure the amenities of the city. Various other schemes were suggested, one of which was to take water from the sea two miles off; practically speaking, they had been hunting for water at Edinburgh for eight years. It so happened that a new Convener of the Electricity Committee was appointed, who was a Commissioner of the Waters of Leith Sewers. He suggested that they should use the sewer for this purpose. This had a flow on an average of 5,000 cubic ft. per minute, and they finally decided to adopt the suggestion. The arrangement had worked entirely satisfactorily with the exception of some trouble in the straining arrangements which would shortly be overcome. As they were tied down not to exceed 90° F. it would be seen that a good deal of water was required per lb. of steam.

Mr. CRAWFORD (Belliss & Morcom, Ltd.), whose remarks were imperfectly heard at the reporters' table, referred to the steam consumption of the turbines mentioned by Mr. Blackman, namely, 17 lbs. per kw.-hour, and suggested that the steam consumption of the reciprocating engines was only 10 per cent. more, which was not at all out of the way, considering the difference in size. The turbine in its best form, he said, was as an exhaust steam turbine, and was then a very proper and efficient adjunct to the reciprocating engine. An ideal system would be a high-pressure turbine with very high temperature and high superheat, exhausting into a reciprocating engine, and from that exhausting into a low-pressure turbine, and they would then get a consumption of about 15 per cent. better than anything extant, and considerably higher than the thermal efficiency of any gas engine. He believed this was very likely to be the practice of the future.

Mr. A. G. COOPER (Chief Electrical Engineer, Colne), speaking on Mr. Lunn's Paper, said that in addition to the transmission of heat being adversely affected by oil, it was also affected by the water which was condensed, and it was necessary to get rid of this from the outside of the tubes as quickly as possible. To this was due the success of the "Contraflo" condenser. With regard to evaporative condensers, Mr. Lunn had missed the real objections to these. In this country good hygrometric conditions were not obtainable, as the humidity of the atmosphere often approached 95 per cent. A second objection to this type was the tremendous number of joints in the pipes. Mr. Cooper next questioned some of Mr. Lunn's figures with regard to a condenser of the low-level counter-current jet type, and also referred to the trouble often experienced in correcting for above sea-level or altering the barometer. The question of air getting into the water depended upon the type of pump in use, and he had found the most satisfactory pump in this connection to be a centrifugal pump with water-packed glands. He had recently fixed one of the latest types of multi-jet ejector condenser. The old type of ejector condenser had a solid stream of water about 1¼ in. in diameter, which only offered a small surface to the steam. They now split this up into eight, which gave a great deal more surface, and, in consequence, a better vacuum—something like 2 in. more for the same quantity of water. A point not touched upon in the Paper was that vacuum gauges were apt to go wrong.

Mr. H. FARADAY PROCTOR (Chief Electrical Engineer, Bristol) said that at Bristol there were eight turbines varying from about 1,000 kw. to 3,000 kw., and some of them had been in for several years. One of these turbines, a 1,000-kw. set, not in its most spick and span condition, the blades being somewhat loose, had run in this condition continuously for nearly two months, and he worked out that this represented a non-stop run of four times round the world. The reason for this long run was that the other two were broken down—but not the steam end. He would like to have the opinion of turbine manufacturers on the point as to whether a turbine shaft, after it had been bent two or three times owing to accidents, was likely to be reliable again when it was straightened, either with or without annealing. One manufacturer has stated that it would, but he could not get financial guarantees on the point. Whilst a turbine of the Parsons type would continue to run with stripped blades, one of the most serious defects was the whip of the shaft after a strip. He believed, however, that in the latest machines this would be got over, as the makers were strengthening up the diameters of the rotor spindles.

Mr. F. W. PURSE (Chief Electrical Engineer, Watford) said he was diametrically opposed to the opinions in the Paper as far as small stations were concerned. Even if they put in a turbine at all, 750 kw. was too small a unit. The author had mentioned 19¾ lbs. of steam per kw.-hour at 28 in. vacuum, and 20½ lbs. with a 26 in. vacuum for the consumption of a steam turbine, but Mr. Crawford could supply an engine with a 26 in. vacuum at 19½ lbs., at which vacuum the turbine would take 21 lbs. of steam. Quite recently he had tenders for a 500-kw. turbo, he being obliged to put this in owing to the foundations and pipe work being already there, and he chose the reaction type of turbine as the lesser of two evils. He received tenders from five makers, namely, Richardsons-Westgarth, Willans, Brush, Westinghouse, and Parsons, and the averages of the steam consumptions from the five firms were as follows:—Full load, 19·4 lbs.; three-quarter load, 20·7 lbs.; half load, 23·6 lbs.; quarter load, 32·1 lbs. Against this he knew that Messrs. Belliss were prepared to guarantee a 500-kw. set with 26 in. vacuum at 17·8 lbs. of steam, against 19·4 for the turbine, and at half load 19·4 lbs. against 23·6 for the turbine. As a further comparison, Mr. Purse quoted the costs at Bradford, Burslem, Aberdeen, Bury, and Stalybridge, in which reciprocating engines are used, to show that they are less than the turbine stations at Cambridge, Loughborough, Marylebone, Melton Mowbray, Brighton, Scarborough, West Bromwich, and the Newcastle & District Co.

Mr. J. V. ROBINSON (Richardsons, Westgarth & Co.) could not agree with Mr. Blackman's axiom that for speeds of 3,000 r.p.m., and below 1,000 kw. the impulse type was better than the reaction type. The author had advocated higher speeds, and Mr. Robinson said his firm was now in a position to supply 1,500-kw. turbines running at a speed of 3,000 r.p.m., but, as far as he knew, there was only one alternator maker who was prepared to supply an alternator for coupling to that turbine. There was no doubt that the higher speed turbines were cheaper, and they took up less floor space and were more economical. He did not agree with the author that the best steam pressure was 150 lbs. per sq. in., nor with his limit for superheat (150° F.). The big turbines to which Mr. Morison had referred were designed for 200 lbs. They had turbines at work for 570° F. superheat, and were building others for 600° and 630° F. With saturated steam the thermal efficiency ratio of a steam turbine was 59 per cent.; with steam superheated to 570° or 600° F., it might rise to about 65 per cent. In this calculation he had accepted the definition of efficiency ratio put forward by the Institution of Civil Engineers' Steam-Engine Trial Committee. Mr. Blackman's figure of £100 per annum for repairs per ten million units generated worked out to 1s. per kw. on the assumption that this ten million units were generated

Digitized by Google

by one 2,000-kw. turbine. This was exactly double the figure given by Mr. Fox at a meeting of the Institution of Electrical Engineers some time ago (ELECTRICAL ENGINEERING, February 18th, 1909, p. 172). Mr. Blackman's own costs, namely, £35, worked out to 4·2d. per kw. His firm supplied a 750-kw. turbine a considerable number of years ago to a works in Middlesbrough, and after four years' running, the total cost for wages, including overhauling and maintenance for the year to February 29th, 1908, was £3 8s. 3½d., which amounted to 1·1d. per kw. installed. He was able to give the results of tests upon the turbines at Glasgow, which were 3,000-kw. sets supplied by his firm. These sets would give 4,000 kw. without the use of the by-pass. The steam pressure, which should have been 150 lbs., was 146 lbs. on test. The maximum temperature of the steam was 572° F., with 93·3 per cent. vacuum, or 28¾ in. The consumption at 25 per cent. overload was 14·3 lbs. per kw.-hour, at full load it was 14·66, and at three-quarter load 15·47. In arriving at these consumptions, they had only to be corrected for superheat, the temperature of the steam being 491 instead of 572. For that adjustment he had allowed 7·2 per cent., a figure which he would be glad to take either way.

Mr. H. RICHARDSON (Chief Electrical Engineer, Dundee) criticised Mr. Purse's statements. He also expressed his pleasure at the results in Mr. Blackman's Paper, because the conditions laid down were practically the same as those which he had chosen for Dundee after very careful consideration.

Mr. S. J. WATSON (Chief Electrical Engineer, Bury) touched upon the point as to whether electricity or steam should be used for driving the air and circulating pumps. Motor driving perhaps had an advantage in first cost over steam, but if a proper method of coupling on to the pumps was adopted, exceedingly economical results could be obtained with steam up to a fair size. At Bury all their condensers were steam driven, and the size was such that they would handle 25,000 lbs. per hour. The steam consumption on the compound engine driving the condenser was about 350 lbs. per hour, and the i.h.p. of the two cylinders working on its own condenser was in the order of 20, so that the steam consumption in this case was about 17 lbs. per i.h.p. In giving steam consumptions for large generators, the power used for the electric driving of the auxiliaries was frequently overlooked. In the case of Mr. Pearce's sets, for instance, he supposed the h.p. required to drive the auxiliaries must be something of the nature of 100 to 120 h.p. This represented an income of about £400 to £500 per annum in units sold. With larger plants, steam-driven pumps had the additional advantage that they could be arranged to exhaust from the low-pressure cylinder slightly above atmosphere and taken into the lower stages of the turbine.

Mr. S. E. FEDDEN (Chief Electrical Engineer, Sheffield), who had had turbines for four or five years, had never had a serious strip, and a possible explanation of this was that they did not run their superheat up too high, although they used 200 lbs. steam pressure. He disagreed with the author on this point. After four or five years at Neepsend, the maintenance amounted to £109 for 9,500,000 units, which was very near to Mr. Blackman's figures. He had recently tested a 4,000-kw. turbine which had been running since November, and the figures were as follows, after corrections for superheat. At 2,000 kw. the steam consumption was 15·46 lbs.; 3,000 kw., 14·71 lbs.; 4,000 kw., 14·01 lbs.; and at 5,000 kw., 13·43 lbs. With the by-pass a little bit open at 6,000 kw., the consumption was 14·1 lbs. This gave an efficiency ratio of very nearly 70 per cent. He did not think that any impulse turbine maker would say he could come anywhere near this efficiency. He had been in the Fisk Street station at Boston two or three years ago, where the steam consumption week in and week out was 23 lbs. per kw. with plants of 5,000 kw. up to 9,000 kw. At the Kingston-on-Thames meeting of the Association a few years ago, he had referred to an oil consumption of 0·0225, and they might remember that a lamp fell off the pedestal and everybody laughed, but he thought when he read in the paper 0·0009 all the arc lamps would start jumping.

Mr. T. W. BLOXAM (Chief Electrical Engineer, Belfast) said that two or three years ago after consideration at Belfast it was decided to put in steam turbines of 1,000 kw. capacity. Two of these sets had now been in use for nearly twelve months, and these offered a very fair comparison with three reciprocating sets which had been in use for three years. Although about 2 lbs. per kw.-hour less steam consumption was guaranteed with the reciprocating engines, he found that the steam consumption of the former had fallen 2 lbs. in two or three years, so that the consumptions of the two types of machine were now about equal. The repairs on reciprocating engines had been very heavy, notably on piston rings. Up to the present there had been absolutely no repairs on the turbines. With regard to relative reliability of the two types, he had had a rather conspicuous illustration in the case of the reciprocating engines. Some water had been inadvertently sent over, and the result was that the low-pressure cylinder of a reciprocating engine was broken, not only the cover, but the whole cylinder, and it cost £250 to repair, the set being out of commission for twelve weeks. A similar occurrence happened in connection with the turbine. Owing to rather hasty draining of a superheater in opening the boiler to the range, one of the assistants inadvertently gave the turbine sufficient water to pull it up and bring the pressure down to nothing on the switchboard, but nothing happened, and the steam consumption soon afterwards was the same as it was after the official test. There was no sign of stripping.

Mr. CRAWFORD (Belliss & Morcom) interposed that the three reciprocating engines to which the last speaker referred were built by a firm of engine builders who were notoriously inexperienced with this type of engine, and who would never build such an engine again.

The PRESIDENT, Mr. S. L. Pearce, in winding up the discussion, said that the price of both the Curtis and the Zoelly types were substantially higher than those of Parsons or Willans turbines, and if there was nothing much between the two types as regards steam economy, then price was going to decide. If he had been satisfied three years ago that any British makers could have built him a 5,000-kw. impulse turbine, that type would have gone into Stuart Street, but he could not get such a machine; there was no denying the fact that in spite of the prestige and influence which was exercised by the firm of Brown Boveri, the Parsons type was losing very fast on the Continent. It would not be long before he was in a position to publish results to show which of the two sets at Manchester (the Willans and the Howden-Zoelly) came out the best. The generating plant and the condensing plant were exactly identical, and he would not be satisfied with the official test, but would have tests made over a long period of time. But this did not eliminate the question of price. Mr. Gregory had touched upon the efficiencies, and had given some figures of the efficiencies of the Curtis turbine. He had heard in Berlin of the wonderful figures from the 6,000-kw. set at Moabit of 12 lbs., or slightly over per kw.-hour. When the tender came in for the second set at the Stuart Street station, he had fully expected that the makers of the Curtis turbine would have easily given the lowest figures, but that was not so, and, if he remembered rightly, the A.E.G. themselves would not guarantee under the Manchester conditions anything like such steam consumption figures as were offered by the Parsons, Willans, or Zoelly makers.

Mr. A. S. BLACKMAN, in his reply, said that some two and a half years ago he had received the most positive assurances from impulse turbine makers that nothing in the nature of blade erosion need be apprehended, but they did not seem to be so confident on the point now. He might be inclined to agree with Mr. Woodhouse that exhaust steam turbines were only temporary, if he were in the happy position of having an up-to-date turbine station. Unfortunately, he had got a very large proportion of reciprocating engine plant. These were exceedingly good engines of their class, and he would not for a moment contemplate scrapping them. Therefore the only thing to do was, as extensions were wanted, to provide the engines with exhaust steam turbines. It was a question, of course, whether it would be better to go for an exhaust steam turbine pure and simple, or to put in a mixed steam-pressure turbine; at the moment he felt rather inclined to go for simplicity, because the engines at Sunderland were so good that he thought it worth while making a permanent arrangement of it. With regard to Mr. Purse's comparative figures of costs of reciprocating engine stations and turbine stations, so far as Bradford was concerned, it must be borne in mind that the figure of 0·23 for coal costs had been achieved, not with the ordinary type of reciprocating engine as represented in electricity works, but with large slow-speed variable expansion engines. But as the results obtained by these engines could be so nearly approached by very much cheaper plant, they were not worth while putting in under present-day conditions. Again, Mr. Purse had included some exceedingly small stations in his turbine stations. Criticism had been made of his limit of 150 degrees of superheat for a turbine installation, but he thought it would be generally accepted that nine-tenths of the turbine troubles had been caused by going up in excess of that figure.

Mr. LUNN indicated his intention of communicating his reply to the Proceedings.

In the afternoon the majority of the members took advantage of the invitation issued by the British Westinghouse Electric & Manufacturing Co., Ltd., and visited this company's fine works in Trafford Park. Considerable interest was taken in the turbines and generators that are being built for the London County Council Tramway Power Station. These were seen in a fairly advanced stage of manufacture, and particular notice was taken of the Rateau blading and the generator rotor, the design of which is of a special nature. The new Le Blanc condensers were also seen, and a magazine flame arc lamp which is now being placed on the market by the company.

THE ASSOCIATION DINNER

THE annual dinner was held at the Midland Hotel on Thursday evening. In proposing the toast of "Local Authorities," Mr. W. W. Lackie mentioned that Manchester and the surrounding districts had provided one-tenth of the £86,000,000 which was invested in electrical undertakings in Great Britain.

Digitized by Google

The Lord Mayor replied. Municipal councillors, he said, were subject to great abuse, and when, as was frequently the case, the accusations were proved to be without foundation, the accuser never had the courage to come forward and say he had made a mistake. A feature of the Manchester Corporation was that the profits of their trading undertakings were not fictitious. Mr. R. Matthews (Past President, Manchester Association of Engineers) proposed the "Incorporated Municipal Electrical Association," and Mr. R. L. Pearce, in the course of his reply, said that in Manchester there was one million horse-power installed, but only about 5 per cent. was connected to the Manchester supply mains. The toast of "Our Guests" was proposed by Mr. J. Christie, and responded to by the Dean of Manchester and Mr. F. Ashworth (President of the Manchester Chamber of Commerce).

THE ANNUAL GENERAL MEETING

THE Annual General Meeting was held at the Municipal School of Technology, at 10 a.m., on Friday, June 25th, Mr. Pearce being in the chair. The first business was the election of officers and filling the vacancies on the Council. The ballot resulted as follows:—

PRESIDENT: W. W. Lackie (Glasgow).

VICE-PRESIDENTS: J. Christie (Brighton), (Senior), G. Wilkinson (Harrogate), (Junior).

PAST PRESIDENTS: S. E. Fedden (Sheffield), H. Talbot (Nottingham), S. L. Pearce (Manchester).

HON. SOLICITOR: Alderman G. Pearson (Bristol).

HON. TREASURER: J. E. EDGCOME (Kingston-on-Thames).

HON. SECRETARY: H. Faraday Proctor (Bristol).

COUNCIL: A. C. Cramb (Croydon), A. A. Day (Bolton), Councillor Howarth (Manchester), V. A. H. McCowen (Salford), H. Richardson (Dundee), Alderman West (Coventry), Alderman Wilkinson (Luton), C. Furness* (Blackpool), F. M. Long* (Norwich), C. E. C. Shawfield* (Wolverhampton), T. P. Wilmshurst* (Derby), Councillor Sinclair* (Swansea), Alderman J. P. Smith* (Barrow-in-Furness), Bailie Willock* (Glasgow).

New members of Council and those re-elected are marked with an asterisk. Alderman Bruce (Sunderland), Mr. F. M. Long (Norwich), Mr. C. E. C. Shawfield (Wolverhampton), Councillor Sinclair (Swansea), Alderman J. P. Smith (Barrow-in-Furness), Mr. G. Wilkinson (Harrogate), and Mr. T. P. Wilmshurst (Derby), retired from the Council in the ordinary course. It will be seen that of the retiring members, Mr. Wilkinson, of Harrogate, was elected Junior Vice-President, and the following were re-elected:—Mr. F. M. Long, Mr. C. E. C. Shawfield, Mr. T. P. Wilmshurst, Councillor Sinclair, and Alderman J. P. Smith.

The place of meeting in 1910 was unanimously decided to be Glasgow, and Mr. W. W. Lackie said the Association would receive a most hearty welcome there.

A photograph and biographical notice of Mr. Lackie appears on p. 599.

Report of the Council

MEMBERSHIP.—The membership of the Association now stands at 390, made up as follows:—Committees (members), 167; chief electrical engineers (members), 176; honorary members, 3; chief assistants (associate members), 8; assistants (associates), 36. Mr. J. F. C. Snell, a past president, has accepted honorary membership of the Association.

Economic Wiring.—Your Council has given careful attention to this question, and has appointed a sub-committee consisting of Messrs. J. Christie, H. Faraday Proctor, J. E. Edgcome, G. Wilkinson, and A. C. Cramb, to inquire further into the matter. The committee reports having circularised all the members of the Association, and the replies received were unanimously in favour of permitting less costly work than under the present methods of casing or conduits. The Cable Makers' Association has promised at an early date to go most fully into the whole matter with its members, and, if possible, draft a specification for a suitable standard class of cable and fittings. Your representatives on the Institution Wiring Rules Committee further report that this committee have decided to consider separately that section dealing with flexible wiring, at a special meeting to be held shortly

Electric Lighting Acts (Amendment) Bill: Supply by Non-Statutory Companies.—The Bill, as promoted, contains some suggestions made to the Board of Trade by your representatives at interviews which the Board of Trade granted, those especially noteworthy being:—A clause enabling the Board of Trade to authorise undertakers to supply premises outside their area of supply under certain conditions. A clause which gives power to local authorities to provide and hire out fittings, &c. In consequence of the amendment to the clause proposed by Lord Avebury, and passed by the House of Lords, a circular letter was issued to Members of Parliament, as well as to the whole of the members of our Association, asking that they should use their influence to get the clause passed in the form in which it was drafted, so that local authorities might be left with a free hand and not be compelled to have such works carried out by contractors who, it was feared, might form a ring and thus increase prices. This circular also advocated the insertion of a new clause as follows:—"Where in any area a Local Authority, Company or Person is authorised to supply electricity under Act of Parliament or under Licence or Provisional Order granted under the Electric Lighting Acts, it shall not, after the passing of this Act, be lawful without the consent of such Local Authority, Company, or Person, for any other Local Authority, Company, or Person to supply, distribute, or transmit electricity within the same area unless such supply, distribution, or transmission is authorised by Act of Parliament, or by Licence or Provisional Order granted in terms of the Electric Lighting Acts." As it was felt desirable that the Bill should be passed this session, it was decided not to oppose on the second reading in the House of Commons, but get it referred to a committee, when the various points could be more conveniently discussed than in the House.

Financial Organisation and Administration.—Your Council has been engaged in conjunction with the Municipal Tramways Association in considering the action which is being taken by the Institute of Municipal Treasurers and Accountants (Incorporated), and a Departmental Committee in relation to the accounts of local authorities. The Municipal Tramways Association is taking the lead in this matter, but your Council is actively co-operating with them. [The report then gives a *résumé* of the draft regulations drawn up by a sub-committee of the Institute of Municipal Treasurers and Accountants, which we summarised in our issue of June 17th, p. 563.] These regulations have apparently been drawn up without consultation with the heads of any municipal trading departments, and an attempt is being made by the Institute of Municipal Treasurers and Accountants, to get them approved and adopted, or recommended by the Local Government Board. If the matter is allowed to go through on the proposed lines, the control of every department, whether trading or non-trading, will centre in the Finance Committee and the Financial Comptroller, who will override the powers now exercised by the other committees and chief officers of the various departments. Having regard to these draft regulations as put forward by representatives of the Institute of Municipal Treasurers and Accountants, and also to the report of the Departmental Committee, which tends in the direction of taking away the accountancy and stores work of all trading departments from such trading departments, and putting it under the control of a central accountant, it is evident that some accountants, at any rate, are endeavouring to get supreme control of all work carried out by local authorities. Needless to say, this would be most disastrous, more especially to all the great trading departments carried on by municipalities, where it is essential that for the proper and economical working of the department, the same should be self-contained and each under one head. The Departmental Committee issued its report after receiving evidence from twenty-eight witnesses, including no engineer manager of any trading department. It has been suggested that the proposals are too obviously unworkable and ridiculous to be worthy of serious attention. Since, however, the Departmental Committee has considered a section of the scheme after hearing one side of the question only, it is imperative that the matter be at once taken in hand.

Income Tax and Depreciation.—Your Council has had its attention drawn to the fact that the Institute of Municipal Treasurers and Accountants has approached the Chief Inspector of Taxes and the Board of Inland Revenue with a view to getting standard rates of allowances for wear and tear. Your Council feel that in questions of wear and tear of machinery and other works, the technical managers should be consulted, and it has, therefore, taken up the matter with the above-named Institution, which, however, in this matter also has apparently endeavoured to evade co-operation, although the matters dealt with are essentially questions involving engineering experience. Your Hon. Secretary had an interview with the Superintending Inspector of Taxes (Mr. E. S. London) at Somerset House, and received a draft copy of the terms as agreed between the representatives of the Board of Inland Revenue and those of the Institute of Municipal Treasurers and Accountants. Mr. London stated that the matter had gone too far to be re-opened, but with this your Council cannot agree, and it is incumbent on every municipality to appeal against the proposals as at present drafted, and where possible to withhold the payment of income tax until the matter is arranged upon a satisfactory basis.

The following are some extracts from the agreed terms to which exception are taken:—

CABLES.

"In addition to repairs allowance for depreciation shall be granted at the rate of 3 per cent. per annum *on the written down value.*"

PLANT AND MACHINERY.

"On all other plant exclusive of loose tools, meters, and office furniture depreciation shall be allowed at the rate of 5 per cent. per annum *on the written down value* in addition to the cost of repairs."

Digitized by Google

Conduits, Meters, Loose Tools and Office Furniture.

"No allowance shall be made for depreciation, but annual expenditure on repairs *and renewals* shall be charged as working expenses as and when incurred."

It was explained to your Hon. Secretary that when renewals take place, worn out or obsolete plant being displaced by new material, the outstanding (i.e., written down) value of the old plant would be allowed as a deduction for the purpose of income tax assessment; this, however, is not made clear in the proof handed to your representative by the inspector, and the wording of the above extracts would, in the absence of other matter, imply otherwise. Even if the text be altered so that this deduction is allowed, it results in the postponement of the allowances until plant is worn out, and this is perpetuated as regards all expenditure except that on "Tramway Track," relative to which the Tramways Association have had some say.

Your Council at its meeting held on May 26th resolved :—

That :—Having considered the proposed allowances for depreciation for the purposes of income tax as set forth in the draft handed to the Hon. Secretary, Mr. H. Faraday Proctor, by the Superintending Inspector of Taxes, Mr. E. S. London, on May 25th, 1909. The same are considered inadequate and should not be accepted by Local Authorities.

That :—In arranging allowances for depreciation for the purpose of income tax, full regard should be given to the periods allowed by the Local Government Board for the repayment of loans in respect of similar assets.

The following table shows the periods usually allowed by the Local Government Board. The corresponding annual depreciation allowance, first as a percentage of the principal sum and second as a percentage of the written-down value, and the percentage of the written-down value and equivalent period as agreed by the Municipal Treasurers' Associations.

	Local Government Board Allowances.			Inland Revenue and Treasurers Agreed Terms.	
Item.	Period of Loan. Years.	Percentage per Annum on original Sum.	Percentage per Annum on written down Value.	Percentage per Annum on written down Value.	Equivalent Life. Years.
Buildings	30	3	7	Not mentioned	
Cables (laid solid) ...	25	3½	9	No allowance for Conduits until renewed.	
Switchboards ...	25	3½	9	5	45
Dynamos	20	4½	11	5	45
Steam Generators...	17	5½	12½	5	45
Engines					
Motor Transformers	15	6	14	5	45
Instruments					
Cables (in ground) ..	15	6	14	3	75
Lamp Pillars, &c....	10	9	21	—	—
Steam Piping ...	10	9	21	5	45
Accumulators ...	7	13	28	5	45
Arc Lamps	5	18	37	5	45

The above figures indicate the allowances or periods required to reduce to 10 per cent. of the original sum approximately. The table shows that the two Government departments go to extremes—the one department allowing for the life of a cable being five times as great as that allowed by the other department—and the extremes in each case operating to the disadvantage of the municipalities, of course. The same inconsistency is noticeable throughout. The Board of Inland Revenue, with the concurrence of the Institute of Municipal Treasurers and Accountants, allow for the life of switchboards being twice as great, machinery generally three times, and arc lamps nine times that allowed by the Local Government Board.

Factory and Workshop Act, 1901.—Since the last annual report was presented to you, the Home Office have issued regulations for the generation, transmission, and use of electrical energy in premises under the above Act. As it is very probable that certain difficulties will be found in conforming to some of them, it is suggested that members who meet with such should communicate with your Honorary Secretary, giving, as concisely as possible, the particulars of the difficulty and the manner in which it has been overcome. It is proposed, in due course, to summarise the points raised, submitting the same or any of them to the Home Office, if necessary, when members will be advised as to the results.

Discussion

Only two points in the report were discussed, viz., the Electric Lighting Acts (Amendment) Bill and the proposed rules by the Institute of Municipal Treasurers and Accountants.

Electric Lighting Acts (Amendment) Bill.

Mr. H. Faraday Proctor, the Hon. Secretary, recapitulated the statements in the report concerning this Bill. Active steps were being taken, he said, to get the Select Committee of the House of Commons to which the Bill is referred, to insert the proposed new clause relating to supply by non-statutory undertakers. With regard to clause 16, relating to wiring work being carried out by municipalities, but only through contractors, Mr. Proctor pointed out that the Council desired an expression of opinion from the members as to how they should proceed in the matter. Were they to accept the amended clause as it now stood, or were they to stand solidly for the rejection of the whole Bill if they could not get it? There was another alternative, viz., to try and secure the rejection of the clause unless it were modified so as to leave the contractor out of it. The Council itself were of the opinion that the remaining clauses in the Bill were too valuable to lose.

In the discussion which ensued there was a sharp division of opinion as to the manner in which the Bill should be dealt with, although all the speakers were of the opinion that the clause must not be accepted as it stands. Eventually a resolution was put to the meeting and carried, to the effect that in the event of it being impossible to get the clause modified so that municipalities may carry out wiring, &c., without the intervention of contractors, an endeavour should be made to have the clause struck out, but that rather than lose the Bill this session the clause and the Bill should be accepted as it stands.

There are one or two other matters which an endeavour is to be made to alter in the Bill during the Committee stage, and with at least one of them the Board of Trade and the Local Government Board are in agreement with the view of the Association. In the first place, it is pointed out that although provision is made against a landlord distraining upon motors, &c., on hire in respect of unpaid rent, yet it was possible for a mortgagee, if he can get in first, to take away any property of this character, although it may be on hire. Both the Board of Trade and the Local Government Board have agreed that this should be altered.

The stamping of agreements is also dealt with in the Bill, but under the recent decision in the County of Durham Power Co.'s case (reported on another page), the Inland Revenue Officers have managed to render nugatory the clause in the Bill, inasmuch as they have successfully fought their claim for 2s. 6d. per cent. on the capitalised value of an agreement upon another clause of the Stamp Act to the one repealed in the Electric Light Acts (Amendment) Bill. As this is a question of finance, and concerns the Treasury, the Association has to fight this unaided by the Board of Trade or Local Government Board. In fact, it has already been intimated that an alteration of the Stamp Act upon this point must be made by a Special Government Bill and not on a Bill of a general character of the Electric Lighting Bill. Alderman Pearson, the Honorary Solicitor, mentioned several features of the Bill, however, which called for the support of the Association to the Bill in general, and specifically mentioned clause 5, which allows the Board of Trade to issue a certificate authorising electric supply in a neighbouring area, thus dispensing with the need for applying for a Provisional Order in each case.

Financial Organisation and Administration.

Councillor A. Murray (Edinburgh) said he entirely disagreed with the remarks in the report upon this matter, because the Edinburgh Corporation was practically working under the proposed regulations of the Institute of Municipal Treasurers and Accountants. The City Chamberlain was equivalent to the proposed financial officer, and he was responsible for all matters of finance. The proposed regulations simply provided for a special internal audit by an audit department of the Corporation, and he could not conceive why there should be objections to that.

Mr. A. C. Cramb (Croydon) and other speakers wished to know how, under the proposed regulations, the financial officer was to be controlled. Under the regulations there would be practically no internal auditor. An outside independent audit was largely advocated by others.

Alderman Pearson (Bristol) questioned whether any one man could be competent to advise on the expediency of large expenditure upon a number of different trading undertakings. At Bristol, for instance, he would have docks to deal with, which was a very different matter to electricity. He spoke as Vice-Chairman of the Bristol Finance Committee, so that he was not biassed.

Mr. C. Furness (Blackpool) said his Council had unanimously rejected the proposals, although their Borough Treasurer had endeavoured to secure their adoption.

Other speakers referred to the fact that borough treasurers in various towns were trying to work on the lines laid down in the report, and the subject dropped, it having been pointed out that the Institute of Municipal Treasurers and Accountants had itself temporarily ceased to place the proposals actively before the municipalities of the country.

PAPERS AND DISCUSSIONS.

Mr. F. AYTON (Ipswich) offered a suggestion to the Council that at future conventions the reading of papers should be dispensed with, and a number of subjects put forward for discussion. The President promised that the matter should receive the consideration of the Council.

Votes of thanks were passed to the retiring officers and to the Corporation of Manchester and those who co-operated in the arrangements for entertaining the Association during the Convention.

On Friday afternoon, a number of members visited the generating station of the Salford Corporation Electricity Department, and some members also went to the Lancashire Power Co.'s station. The alternative visits to other works mentioned in our issue of July 17th were also made by some of the party on Thursday and Friday, and on Thursday about twenty visitors inspected the new exchange of the National Telephone Co., described in our issue of March 18th, 1909, page 253.

LOCAL NOTES

ACTON: *Street Lighting.*—An agreement has at last been arrived at between the Council and the Metropolitan Electric Supply Co. The electric street lamps are to be used from to-day, and the gas lighting in the streets affected will be discontinued.

BARNSTAPLE: *Workhouse Lighting.*—After some discussion it has been decided to install electric light and not gas in the workhouse.

BATH: *Street Lighting.*—The experimental electric street lighting referred to briefly last week consisted of 100 c.p. Leuconeum metal filament lamps set at almost the same distance apart as the 60 c.p. gas lamps with which they are being compared. The Electric Lighting Committee offer these lamps for £2 15s. per annum each, against the £2 10s. paid to the Gas Company. Satisfaction is expressed at the vastly increased illumination.

BIRMINGHAM: *Street Lighting.*—The Corporation are carrying out an experiment with arc lamps for street lighting, and upon the result will depend the question of utilising arc lamps extensively for street lighting.

BRADFORD: *Tramways.*—The Corporation tramway accounts for the year ended March 31st show a profit somewhat over £16,000. This is slightly lower than last year, the difference being attributed to general trade depression.

BRISTOL: *Merchant Venturers' College.*—The new premises of the Merchant Venturers' College, which include extensive electrical engineering laboratories, were formally opened by Lord Reay last Thursday.

FINCHLEY: *Electricity Accounts.*—The accounts for the year ending March 31st last show that on capital account there was spent during the twelve months £13,405, as against £12,638 in the previous year. The maximum load had increased from 509 to 610 kw., and the amount of current generated had increased from 897,502 units to 980,000 units. The amount sold to consumers was 580,750 units, as against 485,060 in the preceding year, and for public lighting 233,725 units had been sold as against 244,700 in the previous year. The income from private lighting was £9,433, as against £8,000 in 1907–8. The receipts from power had increased from £642 to £797, while the amount for public lighting had decreased from £1,685 to £1,678. The cost of coal had increased from £2,491 to £3,036. The balance carried to net revenue was £6.809, as against £5,550 last year. After payment of interest and instalments of principal, there was a balance of £86 odd to carry forward, as against a deficit of £292 last year. The Chairman of the committee (Mr. Todd) said they hoped soon to be able to make a reduction in the price of current to large power users. They had also under consideration the question of concessions to those supplying electrical fittings, and to tradesmen who wished to use arc lamps for lighting their shops.

GOSPORT: *Street Lighting.*—It has been decided to give the gas company 12 months' notice of termination of their contract for street lighting, in order to leave the Council free to adopt electric lighting if they so desire.

HALIFAX: *Tramways.*—The Board of Trade have refused to sanction the doubling of the lines in Northgate, and the construction of a line in George Street and a loop in Orange Street.

HANDSWORTH: *Tramway Arbitration.*—The arbitration proceedings as to the price to be paid by the Council to the City of Birmingham Tramways Co. for the cable tramways in Handsworth has been concluded in London, and the award of Mr. Graham Harris, the arbitrator, will be issued in due course.

HASTINGS: *Electricity Accounts.*—The working expenses for the year ended March 31st are reported as £9,790, of which actual generating costs represented £5,565. The receipts from sale of current were £12,888: with the inclusion of capital charges, however, a deficit of £3,801 is shown. The total units sold amounted to 755,372, against 821,671 the previous year, and the maximum had also declined from 615 to 591 kw.

HORNSEY: *Tramways.*—The Town Council decided last week to consent to the purchase by the Middlesex County Council of that portion of the Highgate Hill tramways within the borough of Hornsey.

IPSWICH: *Electricity and Tramways Accounts.*—The report of Mr. F. Ayton, Chief Engineer and Manager, states that working expenses amounted to £9,496, which, with the addition of capital charges, brought up the total expenditure to £15,397. The total revenue was £15,391. These figures do not include the replacing of boiler settings and instalment for liquidating Parliamentary expenses amounting to £345, so that, including these, the deficit on the year's working is £351, as against £1,789 in the previous year. Considerable benefit is reported to the department through the introduction of metal filament lamps, and the increase in revenue for lighting amounted to 16·32 per cent. The working of the tramways has, however, resulted in a deficit of £2,294, which is somewhat more than the previous year.

LLANDUDNO: *Public Lighting.*—Some competitive trials of gas and flame arc lamps have shown that a pair of Welsbach self-intensifying gas lamps can be run at 0·93d. per hour, and a series of eight 7-ampere flame arcs at 0·90d. per lamp per hour, as against 0·94d. for the old arc lamps. It is said that the light from the two gas lamps is about equivalent to that of the old arc lamps, but that the flame arcs gave about double the useful light.

LONDON: *City of London.*—The Bridge House Estates Committee of the City of London Corporation have put forward three schemes for the widening of Southwark Bridge and the construction of tramways over it.

Camberwell.—An electric testing station is to be established, under the terms of the various electric lighting orders, by the London Electric Supply Corporation, at "Oliver Goldsmith" School.

Fulham.—The outstanding capital upon the electrical undertaking on March 31st was £235,112, the amount repaid being £25,788. The revenue from the sale of current during the twelve months amounted to £29,535, as against £25,855 in the preceding year. The total expenditure was £25,962, plus £1,659 in respect of accrued proportions of capital charges, leaving a net surplus of £1,914 as a result of the year's working. During the twelve months the total number of units sold to private consumers was 2,100,781, at an average rate of 2·563d. per unit. Under this head there was a net increase in the receipts of £2,342, while the increase in public street lighting was £1,142.

Poplar.—Negotiations have recently taken place between the Borough Electrical Engineer and the engineer of the Stepney undertaking, for a supply in bulk to Stepney during removal of plant to the new generating station. The contemplated demand is for a minimum of 250 kw., running continuously for 24 hours per day, except for a short interval on Sundays, with liberty to raise the demand to 500 kw. The contract is to run from July 1st to September 30th, 1909, the price to be 0·3d. per unit, for all energy supplied, untransformed, at the Limehouse sub-station, subject to a clause relating to coal strikes. The minimum quantity is estimated at 550,000 units, and this will yield a profit, apart from the beneficial effect on the load, especially at night and on Saturday afternoons and Sunday. This supply is not to affect the operation of the existing agreement for a stand-by supply to Stepney in case of emergency. The committee have agreed to the foregoing arrangement.

MARKET HARBOROUGH: *Electric Lighting Order.*—The Board of Trade have granted the Council an extension of twelve months for putting their Electric Lighting Provisional Order into operation.

MELBOURNE: *Electrical Trade Association.*—A meeting was held on May 18th last in Melbourne at which it was decided to found an Electrical Trades and Contractors' Association among Victorian firms. Mr. P. Rosling was elected president.

MIDDLESEX: *Tramways.*—On June 24th the Highways Committee of the County Council reported that their Chairman had had a conference with the Chairman of the Highways Committee of the L.C.C., and it had been agreed to join with London in a Bill for the proposed tramway from Cricklewood to Marble Arch. Under this scheme Middlesex will construct the tramway (on the overhead trolley system), and widen the road from Cricklewood to Netherwood Street at an estimated cost of £80,000. The portion of the line from Netherwood Street to Bridge Terrace is to be constructed by the L.C.C. at an estimated cost of £70,000. From Bridge Terrace to Marble Arch the tramway is to be on the conduit system, and from Netherwood Street to Bridge Terrace on the dual system of overhead trolley and conduit. The Managing Director of the lessee company has had the proposed scheme under consideration, and he is prepared to recommend his Board to take a lease of the Middlesex portion of the tramway. The committee is of opinion that the line would be as valuable as any the.

Digitized by Google

County Council has, and this view is shared by the lessee company. It would also be the means of making the line from Cricklewood to Edgware, which at present is the least remunerative one in the county, a success. On the recommendation of the committee the Council passed a resolution approving of the principle of the proposed scheme.

MIDDLETON: *Electricity Accounts.*—An increase in expenditure of approximately £500 is reported, but owing partly to the introduction of metal filament lamps the increase in revenue has only been £180, notwithstanding some considerable additions to the power load. The loss on the years' working is £822.

NAIRN (N.B.): *Electric Lighting Order.*—The Board of Trade have revoked the Council's electric lighting provisional order.

NEWPORT (Mon.): *Electricity Accounts.*—The report of Mr. H. Collings Bishop (Borough Electrical Engineer) states that although there have been slight decreases in the lighting and traction revenue, the gross profit was £16,408, against £15,039 for the previous year. With capital charges, &c., however, the electric supply accounts show a deficit of £1,469. The tramway department, however, has made a net profit of £1,663. Certain modifications of the tariff are recommended, which would result in increased revenue.

NEWTON-IN-MAKERFIELD: *Electric Lighting Order Revoked.*—The Board of Trade have refused the Council's application for an extension of time for 12 months in which to put their electric lighting provisional order into operation.

SOUTHAMPTON: *Supply to the Docks.*—The Borough Electrical Engineer has been in communication with the Chief Engineer of the London & South-Western Railway Co., as to the supply of energy to the docks, the present supply from the company's own works being insufficient. At the first interview the negotiations were on the basis of half-a-million units per annum, and the company offered 1¼ per unit. The expenditure for mains for this supply would be about £1,650. Subsequently the company's Chief Engineer asked whether the Corporation would be prepared to supply the whole of the dock with electricity. The output at present is about one and a quarter millions. At the end of the present year it will be about one and three-quarter millions, reaching two millions on the completion of the new wet dock. The price offered was 1d. per unit, which would bring in a revenue of between £7,000 and £8,000 per year. The Borough Electrical Engineer informed his committee that the present opportunity appeared the last the municipality would ever have of supplying that undertaking with electricity. The company's requirements during December and January in each year between 5 p.m. and 10 p.m. are very small, and they would be prepared to do without the Council's supply during those months between the hours named, that being the period and time of the other consumers' heaviest demand. The committee decided to accept the offer of the company for a supply at 1¼d. per unit on a consumption of not less than 400,000, and not more than 600,000 units per annum conditionally that the supply is a day load, and is partially discontinued between the months of December and January.

TEWKESBURY: *Street Lighting.*—Some difficulty has arisen as to the future street lighting owing to the refusal of the Gas Company to renew its existing contract for a period of less than five years, and the requirement of the electricity supply company that the Council should erect the posts and lamps. This the Council do not wish to undertake, nor are they willing to renew the gas contract except subject to a year's notice. Meanwhile, the Gas Company have been asked to renew the contract up to September 30th, and the Surveyor has been instructed to prepare a scheme.

TOTTENHAM: *Tramways.*—The Metropolitan Electric Railways, Ltd., have applied to the Board of Trade for an extension of the time by two years for the completion of the works authorised by the Tottenham and Walthamstow Light Railways Order, 1906. The District Council is not opposing the proposed extension.

UXBRIDGE: *Workhouse Lighting.*—Dr. Lock, the Medical Officer to the Guardians, has written to the Board urging them to consider the advisability of substituting electricity for gas in those portions of the workhouse in which the last-mentioned illuminant is used. Estimates from the Gas and Electric Light Companies are being obtained.

WALTHAMSTOW: *Metal Filament Lamps.*—A recommendation has been adopted with reference to the lighting of shops by means of Osram lamps. The terms are to be as follows:—200-c.p. lamps at a minimum inclusive price for current and maintenance of £2 10s. per lamp per annum, and 100-c.p. lamps at £1 10s. per lamp per annum, the charges to be based on a consumption of 150 and 80 units per lamp per annum respectively. Where the consumers desire to purchase lanterns and wiring on the hire-purchase system the arrangement is to be carried out on lines similar to those in force for the arc lighting scheme.

WEST HAM: *Supply for Power.*—An agreement has been come to in regard to a supply for power to the Traders' Lumber Company, of Chargeable Lane, Plaistow. They are to take a minimum of 12,000 units per annum.

WILLESDEN: *Tramways.*—The Metropolitan Electric Tramways, Ltd., submitted plans in connection with the proposed joining up of the County of Middlesex Light Railways with the London County Council tramways system in Scrubbs Lane. The company are to be informed that before the scheme is approved, arrangements must be made with the London & North Western Railway Co. for widening the roadway on each side of the permanent way to at least 9 ft. 6 in. in width, and a pathway of a minimum width of 9 ft.

YARDLEY: *Tramway Supply.*—It has been decided by the Council, on the recommendation of the Tramways and Electric Lighting Committee, to give notice of terminal of the agreement with the City of Birmingham Tramways Co. in order to make it possible to frame a scheme for putting into operation the Council's Electric Lighting Orders.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

ACTON.—Tenders are invited for lead-covered paper insulated cable. Particulars from J. Martin Blair, 130 Churchfields Road, Acton. Tenders by July 12th.

DUBLIN.—A Local Government Board inquiry has been held regarding a proposed loan of £100,705 for plant and main extensions.

A loan of £3,800 for the electrical installation at the Richmond District Asylum is to be applied for.

LONDON: *St. Pancras.*—The sanctioning of a loan of £3,299 for electric lighting in St. Pancras is recommended by the Finance Committee of the L.C.C. The amount is made up as follows:—Mains, £302; switchboards, £350; house services, £1,646; meters, £1,001.

PONTYPRIDD.—Tenders are invited for the supply and delivery of a surface-condensing plant, together with circulating pump, air pumps, pipe work, &c., for the tramways department. Particulars from the Electrical Engineer and Manager, and tenders to the Clerk by July 12th.

RADCLIFFE.—The Local Government Board has sanctioned a loan of £4,336, repayable over 17 years, for additional plant for the generating station.

SHREWSBURY.—The Council has agreed that application be made to the Local Government Board for a loan of £10,000 for extensions to the electricity works.

WALLASEY.—Tenders are invited for a battery of accumulators, reversible booster, and switchboard. Particulars from Mr. J. A. Crowther, Sea View Road, Liscard. Deposit, one guinea. Tenders by July 12th.

WHITCHURCH.—An inquiry was held last week on behalf of the Local Government Board into an application by the Dinas Powis Rural District Council to borrow £2,960 for the purpose of electric lighting in the parish of Whitchurch.

Miscellaneous

HASLINGDEN.—Tenders are invited for sub-station equipment with battery and reversible booster. Particulars from Messrs. Handcock & Dykes, 1 Victoria Street, S.W. Deposit, one guinea. Tenders by July 3rd.

MANCHESTER.—Tenders are invited for special tramway trackwork. Specifications from J. M. M'Elroy, General Manager, Corporation Tramways, 55 Piccadilly, Manchester. Deposit, £2 2s. Tenders by July 13th.

SANTA FE (RIVER PLATE).—New tenders are to be invited for the electrification of the city tramways.

SWANSEA.—Tenders are invited for arc lamps, cable, pillars, and lowering gear, and feeder pillars. Particulars from Mr. C. A. L. Prussman, Electrical Engineer. Deposit, one guinea each section. Tenders for lamps and cable by July 7th; remainder by July 12th.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

N.—Latymer School, Edmonton. Builders, W. Lawrence & Son, Tottenham. (£6,782.)

N.E.—Fire Station, Wood Street, Walthamstow (£2,000). Architect, J. W. Dunford, 100c Queen Victoria Street, E.C.

School, Coppermill Lane, Walthamstow. Architect, H. Prosser, High Street, Walthamstow.

Two factories, Higham's Park, Walthamstow, for the British Xylonite Co.

Chemical factory, Blackhorse Lane, Walthamstow, for Baird & Tatlock, 14 Cross Street, Hatton Garden, E.C.

Digitized by Google

S.E.—Improvements at the Sun Street Fire Station, Woolwich (£7,000). Architect, W. E. Riley, L.C.C., Spring Gardens, W.C.

PROVINCES.

ABERDEEN.—Public Hall, Esplanade, Sea Beach. Architect, J. Rust, 224 Union Street, Aberdeen.

BURSLEM.—Schools (£13,088). Architects, A. R. Wood & Son, Burslem.

DUNFERMLINE.—Tenders are invited for the electric lighting of the Lauder Technical School extensions. Particulars from the Clerk to the School Board, 104 High Street, Dunfermline, and tenders by July 10th.

GLASGOW.—Skating rink (£3,000). Architect, T. Boswell, 53 Bothwell Street, Glasgow.

MAIDSTONE (Kent).—London County Banking premises. Architect, W. C. Jones, 23 Bedford Row, W.C.

PORTSMOUTH.—Nurses' Home at hospital (£7,000). Architect, C. W. Bevis, Elm Grove Chambers, Southsea.

SWANSEA.—Additions and alterations Secondary School (£3,150). Architect, G. E. T. Laurence, Chandos Chambers, 22 Buckingham Street, Adelphi, W.C.

TENDERS RECEIVED AND ACCEPTED

BARKING.—The tenders of Messrs. Crompton & Co. for a 250-kw. three-phase alternator (£340), and of Messrs. Siemens Brothers Dynamo Works, Ltd., for a switchboard (£102) and a motor (£80) have been recommended for acceptance by the Electricity Committee.

BURNLEY.—The tender of Messrs. Simpson Brothers, of Burnley and Hapton, for electrical installation at the new technical school (£1,425), has been accepted.

DUBLIN.—The tender of Mr. J. B. Brunker for the supply of motors at Messrs. Tonge & Taggart's iron foundry, Windmill Lane, Dublin, has been accepted at £249. Ten tenders were received, ranging from £255 to £400.

DUNDEE.—The tender of Messrs. Kelvin & James White for a switchboard for the new Technical College (about £300) has been accepted.

HOUNSLOW.—The District Council has placed an order with Babcock & Wilcox, Ltd., at £310, for a mechanical chain grate stoker.

LONDON: *L.C.C. Tramways.*—The Highways Committee of the L.C.C. recommend the acceptance of the tender of Messrs. R. C. Brebner & Co., of Edinburgh, for the execution of woodwork and platelaying exclusive of the supply of rails and special trackwork of the authorised tramways along the Victoria Embankment east of John Carpenter Street, Blackfriars Road, and Southwark Street (£11,420). Tenders were also received from Dick, Kerr & Co. (£12,055), A. N. Coles (£12,745), W. Manders (£13,598), and Mowlem & Co. (£14,707).

The Committee also recommended the existing contract with Messrs. W. T. Henley's Telegraph Works Co., Ltd., for cables to be extended to include L.T. cables required for the tramway extensions from Whitechapel Road to Hackney Road. The expenditure sanctioned is not to exceed £2,750.

Stepney.—The Borough Council has received the following tenders for two years' supply of demand indicators:—Chamberlain & Hookham, Ltd. (informal), £511; Engineering Instruments, Ltd. (informal), £409 9s. 4d.; British Insulated & Helsby Cables, Ltd. (informal), £405 10s.; Reason Manufacturing Co., Ltd. (accepted), £563 5s.; Electrical Co., Ltd. (informal), £1,669 10s.; General Electric Co., Ltd. (informal), £2,397 9s.

The following tenders were received for two years' supply of time switches:—Reason Manufacturing Co., Ltd., £559 10s.; Venner & Co. (accepted), £815.

MANAOS.—Messrs. J. G White & Co. have placed an order with Messrs. Johnson & Phillips, Ltd., for the supply of the main switchboard for the Manaos Electric Light & Power Co.

MIDDLESEX.—The County Council on June 24th placed an order with Dick, Kerr & Co., Ltd., for the construction, at an estimated cost of £45,500, of the Southbury Road, Enfield, tramway (Railway No. 4, Order 1906). The work is to be done on the contract price on which the firm are constructing the Regent's Park Road, Ballard's Lane, &c., and the Cricklewood Lane tramways.

SOUTHAMPTON.—The Town Council has received the following tenders for the supply of cable:—I. Frankenburg & Sons, Ltd.: (*a*) 3,000 yards 1 sq. in. single conductor cable, (1) lead covered, ——, (2) non-lead covered, £1,770; (*b*) 1,500 yards 0·5 sq. in. single conductor cable, (3) lead covered, ——, (4) non-lead covered, £465. W. T. Glover & Co., Ltd. (accepted for *a* and *b*): (*a*) (1) £1,826 8s. 5d., (2) £1,794 0s. 9d.; (*b*) (3) £484 6s. 1d., (4) £470 13s. 5d. St. Helens Cable & Rubber Co.: (*a*) (1) £1,862, (2) £1,817; (*b*) (3) £503, (4) £477. Johnson & Phillips, Ltd.: (*a*) (1) £1,850, (2) £1,820; (*b*) (3) £490, (4) £476. W. T. Henley's Telegraph Works Co., Ltd.: (*a*) (1) £1,850, (2) £1,825; (*b*) (3) £493, (4) £477. Western Electric Co.: (*a*) (1) £1,847, (2) £1,828; (*b*) (3) £491, (4) £478. British Insulated & Helsby Cables, Ltd.: (*a*) (1) £1,853, (2) £1,830; (*b*) (3) £492, (4) £480. Siemens Bros. & Co., Ltd.: (*a*) (1) £1,873 10s., (2) £1,840; (*b*) (3) £495, (4) £484. Callender's Cable & Construction Co., Ltd.: (*a*) (1) £1,950, (2) £1,900; (*b*) (3) £540, (4) £530. The Craigpark Electric Cable Co., Ltd.: (*a*) (2) £2,200; (*b*) (4) £480. The New Gutta Percha Co., Ltd.: (*a*) (2) £3,180; (*b*) (4) £843.

The Town Council has accepted the tender of P. Brotherhood, Ltd., at £60 for an air compressor for the tramways.

SWINTON & PENDLEBURY.—The Council have accepted the tender of Messrs. Callender's Cable & Construction Co. for the supply of cables, service boxes, &c., at £122.

VICTORIA.—The Postmaster-General has accepted the tender of Messrs. Johnson & Phillips, Ltd., for the supply of a submarine cable gear for the Australian Commonwealth.

COMPANIES' MEETINGS AND REPORTS

LEAMINGTON & WARWICK ELECTRICAL CO.—The report for the year 1908 shows a capital expenditure of £779. In October last an issue was made of £35,000 four and a half per cent. debentures in order to provide funds to discharge the company's liability of £28,233 to the British Electric Traction Co., and to provide working capital. The accounts show a credit balance of £5,411 from the tramways and electricity supply. Deducting expenses amounting to £1,354, as well as interest, there is a sum of £2,405, including £139 brought forward. The directors recommend the placing to depreciation and reserve account of £300, making this £4,600, to place to the sinking fund for redemption of debentures (making £700) £350, to pay a dividend of 5 per cent. on the cumulative preference shares for the year, £120, a dividend of 2 per cent. on the ordinary shares for the year, £1,351, and to carry forward £282.

SOUTH METROPOLITAN ELECTRIC TRAMWAYS & LIGHTING CO.—The report for the year ended December 31st, 1908, states that the total revenue amounted to £52,240. After deducting all expenditure, including repairs and maintenance, interest upon the debenture stock, and providing for payments to local authorities under agreements, which together amount to £44,462, there remains a surplus of £8,207. The dividend on the 6 per cent. preference shares for the half-year ended June 30th, 1908, absorbed £4,903, and the directors recommend that £3,000 be placed to depreciation and reserve fund, leaving to be carried forward to next account £303.

ELEKTRICITATS AKT.-GES. (VORMALS LAHMEYER & CO., FRANKFURT).—The company completes the business year 1908-9 with a net profit of approximately £75,300, which will enable a dividend of 6 per cent. to be paid, as against 7 per cent. last year. A sum of approximately £5,300 is to be carried forward.

TRACTION & POWER SECURITIES CO.—A credit balance of £25,775 is shown by the accounts for the year to 1908. The sum of £20,000 has been transferred to investment reserve account, and the balance carried forward. The company's total investments stand at £873,000 in the accounts.

INDIAN ELECTRIC SUPPLY & TRACTION CO.—The report for the year ended December 31st, 1908, states that the year's working in Cawnpore has resulted in a loss of £9, and to this has to be added final interest on construction debentures, £7,500; London expenditure, £2,127; and interest on loans, £912; making a total deficiency for the year of £10,549. With the balance of £6,681 brought forward, the total amount of debit of profit and loss account is £17,231. The tramway working shows a deficiency of Rs5,864, against a deficiency last year of Rs3,772. The position, however, on both sides of the undertaking has improved. In order to pay off the creditors and to provide further working capital, fresh capital will be necessary, and a scheme involving the reorganisation of the company's capital is regarded as being necessary, if the business is to be carried to a successful issue.

BRITISH ELECTRIC TRACTION CO.—The accounts for 1908 show a net profit of £166,119, including £35,393 brought forward, after reserving £12,500 against depreciation of undertakings worked by the company, building and freehold land, stock, doubtful debts, and expenditure on undertakings not proceeded with. After deducting the interest on the 5 per cent. debenture stock and the 4½ per cent. debenture stock for the year, there remains a balance of £68,634, out of which a dividend has been paid on the preference shares at the rate of 3 per cent. for the year, leaving a net balance of £20,203, which the directors propose should be carried forward. The full dividend on the 6 per cent. cumulative preference shares of the company has been paid to March 31st, 1908. The directors regret that the dividends and interest received from the associated companies during the past year show a diminution of £33,331. This result is attributed to the severe depression in trade. The number of passengers carried per route mile has fallen from 662,726 to 654,770, but the effect of this decline has been somewhat counteracted by a small increase in the average fare per passenger, which was 1·23d., against 1·21d. The report points out that the directors are giving attention to electrical enterprise in countries where the conditions for investment are more favourable than in this country, and mentions that a substantial participation has been obtained in a syndicate, including German and other Continental banks, which is endeavouring to secure a concession for the St. Petersburg tramways.

Digitized by Google

British Electrical Federation.—This was formed in 1907, and consists of the B.E.T. affiliated companies, to effect administrative economies, and for the purpose of affording mutual advice and assistance. It is constituted to provide the companies concerned, on a co-operative basis, with directors, managers, secretaries, accountants, engineers, and other officers, as well as with legal assistance, office and other accommodation, and to watch over and protect the general interests of the companies. The report for 1908 has been issued, and gives particulars and statistics relating to the 59 companies and concerns which are at present included in the Federation.

MARCONI'S WIRELESS TELEGRAPH CO.—At the annual meeting on Monday, the report and accounts given in our issue for last week were adopted. Mr. G. Marconi, who was in the chair, stated that since the report was issued the position of the company had continued to rapidly improve, as orders had been received from the Portuguese and Greek Governments. The total value of orders in hand at the present moment was over £100,000. The machinery for the Glace Bay station had nearly all been delivered, and he had no doubt that a very great extension of the Transatlantic service might be anticipated as soon as the complete duplication of the station in Canada had taken place, which would enable the company to accept from 15,000 to 20,000 words per day at Clifden and Glace Bay. It was also expected about the end of August that the company would be in a position to invite the Post Office to give effect to the agreement with the Postmaster-General with regard to the acceptance and delivery of the company's messages at telegraph offices throughout the United Kingdom. Their relations with the British Government were on a most satisfactory basis. Since the issue of the report three influential gentlemen had joined the Board, namely, Mr. H. Heenan, of Messrs. Heenan & Froude, Ltd.; Mr. Whowell, of the Bleachers' Association, Manchester; and Capt. H. Riall Sankey.

"Z" ELECTRIC LAMP MANUFACTURING CO.—The annual general meeting was held on Monday, when the report and accounts were adopted. Mr. J. G. B. Stone, who presided, said that the company had patents in seventeen British colonies and dependencies. He did not think at the present time there was a firm in this country manufacturing so many metal filament lamps as the "Z" Company, and in this connection he drew attention to the great progress which has taken place during the past year. When they first started manufacturing, the 30-40 c.p. 100-volt lamp was the only one they could make, but now they had on the market 16 c.p. 100-volt lamps and 30 c.p. 200-volt lamps. They had now reached a stage when a thoroughly satisfactory metal filament lamp could be placed on the market at reasonable prices, and the best proof of this was that last month they sold the whole of their stock to the trade for forward dates at satisfactory prices. With regard to the patent position they had already successfully maintained it against infringement, and the shareholders might rest assured that in this respect the directors would protect their interests.

GLOBE TELEGRAPH & TRUST.—The Marquis of Tweeddale, at the meeting last Thursday, announced that the receipts for the year, after deducting expenses, were £207,347, only slightly less than last year. The dividend recommended on the ordinary shares would make up a total of 5¾ per cent. for the year. £27,305 is being carried forward.

SOCIETE ANONYME WESTINGHOUSE (PARIS).—The report of the French Westinghouse company shows a gross trading profit of 1,686,000 francs, which, with the addition of 94,500 francs from revenue from investments, &c., and the deduction of 272,800 francs expenses, gives a balance of 806.900 francs, of which 885,000 is available for distribution; 531,000 francs are to be appropriated for amortisation, and 17,700 carried to legal reserve. A dividend of 5 per cent is recommended on the "privileged" shares, with 86,000 francs carried forward.

BIRMINGHAM & MIDLAND TRAMWAYS.—At the meeting last week the report and accounts summarised on p. 560 of our issue of June 17th, were adopted. Mr. J. A. Lycett, managing director presided, and Mr. W. G. Bond was elected to the Board on the retirement of Sir Ernest Spicer.

J. G. WHITE & CO.—The directors' report records a net profit on the year's trading of £39.977. Dividends of 8 per cent. are recommended on the cumulative preferred and ordinary shares. £20,000 is to be carried to reserve, and £15,460 carried forward. Although the depression of trade has reduced the amount of construction business obtainable, the company is carrying out important works in Brazil, Argentina, and other places abroad. At the meeting held on Monday, the report and accounts were adopted.

At the meeting on Monday, the report and accounts were adopted. The chairman, Lord Arthur Butler, stated that the business in hand ensured satisfactory profits for the current year, and negotiations were proceeding for the securing of a considerable amount of new work.

BOMBAY ELECTRIC SUPPLY & TRAMWAYS.—The revenue for 1908 amounted to £177.855, an increase of £49.935 as compared with the previous year, and expenditure was £110.788, an increase of £23,749. After deducting debenture interest and dividend on the preference shares, a balance of £9,385 remained, and was carried forward.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars net, c.i.f. port of arrival, quoted on Tuesday night, was £60 5s. to £60 15s. (last week, £60 to £60 10s.).

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—The United Kingdom Tramway, Light Railway, and Electrical Syndicate, Ltd., is to be wound up voluntarily.

The last day for receiving proofs in the bankruptcy of W. T. Garnett, trading as W. T. Garnett's Cable Co., Barkerend Mills, Bradford, is July 16th. The trustee is Mr. Edgar Musgrave, 1 Bank Street, Bradford. The discharge of this debtor has been suspended for two years.

A petition for the winding-up of the North Western Electricity & Power Gas Co., presented on June 23rd, by Messrs. Harper Brothers & Co., and Messrs. D. Balfour & Co., will be heard on Tuesday next.

A petition for the winding-up of Mountain & Gibson, Ltd., will be heard at St. George's Hall, Liverpool, on Monday next.

At a meeting of the Geneva Tramways Co. (1906), Ltd., it was resolved, in view of an agreement with the Omnium Lyonais de Chemin de Fer et Tramways for the sale of certain shares, the company be wound up voluntarily. The Hon. A. Brand and Mr. J. Seear are appointed liquidators.

Meetings of the Buenos Ayres Electric Tramways Co. (1901) and the Buenos Ayres Grand National and la Capital Tramways Joint Committee will be held on August 5th to receive accounts of the winding-up.

A compulsory order for the winding up of the Uxbridge & District Electric Supply Co., Ltd., was made on Tuesday on the application of Messrs. Callender's Cable & Construction Co., Ltd.

CHANGE OF ADDRESS.—In future the only address of the International Electric Co. will be Telephone Works, 111–115 Salusbury Road, Kilburn, London, N.W., the offices at 55 Redcross Street, London, E.C., having been closed. The firm's telegraphic address will remain, viz., "Genest, London," but the new telephone numbers are 477 P.O. Willesden, and 488 Paddington. A special motor service has been instituted for customers in the London district.

THE "M.A.N."—Owing to the increase of business in their large gas-engine department, and of their intention to take up the direct sale of their Diesel oil engines in England, the Maschinenfabrik Augsburg-Nürnberg A.G., who like to be known by the abbreviated title of M.A.N., have, as a result of a friendly arrangement, terminated their agency agreement with Mr. James Halcrow, 18 Coleman Street, London, E.C., and have opened an office in London. All communications should in future be addressed: M.A.N., 219 Caxton House, Westminster, S.W. Telegraphic address: Klettillo, London. Telephone: 3775 Victoria.

ELECTRICAL FOOTBALL LEAGUE.—A special general meeting is being held in the offices of the St. James and Pall Mall Electric Supply Co., Ltd., 19 Carnaby-street, W., on Wednesday, July 14th, at 7 p.m. The last day for receiving applications from those clubs who intend joining is Monday, July 12th. The Hon. Secretary is Mr. J. W. Fraser, 39 Wearside Road, Lewisham, S.E.

OUTING.—On Saturday, June 19th, the staff of the Sun Electrical Co., Ltd., held their tenth annual outing. This took the form of a trip by Immisch electric launch *Rosalind*, from Reading to Maidenhead, calling at Henley-on-Thames for lunch and at Marlow for tea. In the course of his remarks after lunch, Mr. A. G. Beaver, the manager, said he anticipated that this year's turnover would eclipse all previous years.

ELECTRIC TAXICAB CO.—The resolution for the voluntary winding up of this company has been confirmed. Mr. W. Milne, of 9 New Broad Street, has been appointed liquidator.

MISCELLANEOUS CITY NOTES

NATIONAL ELECTRIC SUPPLY CO.—An interim dividend of 3s. per share, less tax, is recommended on the ordinary shares for the past half-year.

[illegible]STON, PROCTOR & CO.—A new issue is being made of 200,000 5 per cent. cumulative preference shares of £1 each. The subscription list closes on the 5th inst.

SILVERLYTE LAMP CO.—At a meeting last week it was resolved to sell the whole property of the undertaking as a going concern to a new company called Sylverlyte (1909), Ltd., with a nominal capital of £200.000. It is stated that the profits from January 1st to March 31st averaged £300 per month.

National Electrical Manufacturers' Association.—A committee meeting will be held at Balfour House, Finsbury Pavement, London, E.C., on Tuesday, July 13th, at 2 30 p.m.

Torpedo controlled by Hertzian Waves.—It is reported that successful experiments were made in Paris last week with a new dirigible torpedo invented by M. Gustave Gabet, in which the propelling engines and the direction of travel are controlled at a distance by means of Hertzian waves. An official test will be made shortly.

PARLIAMENTARY INTELLIGENCE

PROGRESS OF ELECTRICAL BILLS.—The Oxford and District Tramways Bill was read a third time in the House of Lords on Monday.

The Wallasey Tramways and Improvements Bill was read a third time and passed in the House of Lords on Tuesday.

FOLKESTONE, SANDGATE, AND HYTHE TRAMWAYS BILL.—The Committee of the House of Commons which considered this Bill has agreed to allow the company an extension of time in which to complete the authorised tramways until August, 1913. It will be remembered that the proposal of the company to install a combined overhead and conduit system was rejected by the Committee.

GREENOCK CORPORATION BILL.—When this Bill was before the Local Legislation Committee of the House of Commons a short time ago, the question of the supply of electrical energy by the Greenock Corporation to the Greenock & Port Glasgow Tramways Co. outside the area of the Greenock Corporation was raised, and the other local authorities through whose district the line passes sought to have the power conferred upon them of supplying electrical energy or having a voice in the agreement with the Greenock Corporation. The committee, however, refused to pass this arrangement. The matter was again raised in the House of Commons on Tuesday on consideration of the Bill, but an amendment to this effect was rejected and the Bill read a third time. Mr. Nicholson, the chairman of the Local Legislation Committee, expressed the opinion that it would be better for the matter to be fully discussed in the House of Lords.

APPOINTMENTS AND PERSONAL NOTES

On Saturday last, at the Victoria Hotel, Manchester, a meeting was held of the district managers of the Edison & Swan United Electric Light Co., Ltd., for the purpose of presenting a testimonial to Mr. O. H. Bishop, sales manager to the company, who has resigned after eighteen years' service in order to take up other duties. The presentation took the form of an illuminated address, and a service of silver, subscribed for by the whole of the district managers, and the heads of departments of the northern works of the company. During the same week Mr. Bishop was presented with a gold cigarette case and an address by the sales department staff, and with a gold fitted dispatch case and a gold-mounted letter-case by the heads of departments at the Ponder's End works.

Mr. A. H. Seabrook, who was recently appointed electrical engineer and manager of the Marylebone electricity undertaking, has recommended the appointment of Mr. H. H. Holmes, at present sales manager to the West Ham electricity undertaking, at a salary of £400 per annum, to assist him in the reorganisation of the commercial management. The Marylebone Electricity Committee have adopted the proposal.

Two Deaths by Electric Shock in a Colliery.—On Monday, two miners were killed at the Clifton Colliery, Nottingham. The men were working with an electric coal-cutting machine, and in some way, as yet unexplained, received fatal shocks. An inquest will be held and the matter investigated. It is stated that electric coal-cutters have been in use in this mine for three years, and that this is the first accident that has occurred with one.

Birthday Honours.—Among the Birthday Honours, the Order of C.I.E. has been bestowed upon John Newlands, Esq., officer on special duty in connection with the reorganisation of the telegraph department, and Henry Alexander Kirk, Esq., India Office, late India Telegraph Department, Director-in-Chief, Indo-European Telegraph Department.

Electric Railways in Japan.—An American Consular report states that with the completion of the second section of the municipally-owned electric railway at Osaka, nine miles have been opened to traffic. This includes a line three miles in length to the harbour. Work is now being commenced on the third section (32 miles), and a fourth section (13 miles) is also contemplated. Osaka will eventually be linked with all the neighbouring towns by an electric railway system. Connection with Kobe (the Haushui Electric Railway) and the Hawadera—a seaside resort 15 miles distant on the Nankai Railway—has already been established. It is now proposed to electrify the rest of the Nankai Railway to Wakayama, 40 miles distant. Electric railways to Kyoto and Arima, mineral springs and summer resorts in the hills on the north-west, are also under construction.

NEW COMPANIES

S. M. F. SYNDICATE.—Registered on May 21st, with a capital of £8,000 in £10 shares, to acquire a concession for tramways between Ponte Delgoda and Furnas, in the island of San Miguel, Azores, and to carry on at Azores or elsewhere the business of constructors of tramways and buildings, &c. Minimum cash subscription £1,000. Registered without articles of association. The first directors are P. Burtin, T. Guillard, and G. C. d'Ancourt. Registered office: 21 Liverpool Street, E.C.

LECHLADE ELECTRIC LIGHT & POWER CO.—Registered on May 22nd, with a capital of £400 in £1 shares, to carry on the business of electricians, mechanical engineers, manufacturers, and workers of electricity for power and light, &c. Registered office: High Street, Lechlade, Glos.

BRISTOL ELECTRO-CHEMICAL CO.—Registered on May 25th, with a capital of £500 in £1 shares, to carry on the business of manufacturers of and dealers in carbide of calcium and other chemicals and apparatus, machines, or plant, for the utilisation thereof, &c. Private company. Registered office: Thorp and Saunders, Salisbury House, London Wall, E.C.

BRIDGWATER CONSTRUCTION CO.—Registered on May 26th, with a capital of £1,250 in £1 shares, to take over the business of a constructional, electric, and hydraulic engineer, and ironfounder, carried on by Florence Bridgwater at 453 Holloway Road, N., as the Bridgwater Construction Co. Private company. The number of directors is not to be less than two nor more than four. Registered office, 453 Holloway Road, N.

TAYLOR'S PATENT SAFETY SHUNTING LEVER.—Registered on May 22nd, with a capital of £40,000 in £1 shares, to acquire the benefit of certain existing inventions relating to improvements for operating points and signals on railways and tramways, to adopt an agreement with H. W. Sanderson and S. H. Aldridge, to develop and turn to account the said inventions, and to carry on the business of mechanical, electrical, and general engineers, &c. Private company. Registered by Cox & Lafone, 17 Tower Royal, E.C.

EATON TELEPHONE DISINFECTOR CO.—Registered on May 29th, with a capital of £500 in £1 shares, to carry on the business of manufacturers and suppliers of contrivances and appliances for use in connection with telephones, &c. Private company. Registered office: 36 Jewin Street, E.C.

WALKER HANNA PATENT BEARINGS CO.—Registered on June 8th, with a capital of £2,400, to acquire the patents and rights granted to R. Walker Hanna relating to improvements in the manufacture of brasses or bushes for the bearing of shafts and axles applicable to railways, tramways, &c. Registered office, 2 Booth Street, Manchester.

GRASSINGTON ELECTRIC SUPPLY CO.—Registered on June 8th, with a capital of £1,000, to carry on, at Grassington and elsewhere in Yorkshire, the business of an electric supply company in all its branches. Registered office, 51 King's Arcade, Bradford.

BEAM CO. (BRITISH ELECTRICAL & MECHANICAL CO.).—Registered on June 8th, with a capital of £1,000, to take over the business of an electric, telegraph, and general engineer and contractor, carried on by A. Lawes at 35 Devonshire Chambers, Bishopsgate Street Without, E.C., as the "Beam Co. (British Electrical and Mechanical Co.)." Registered office, 35 Devonshire Chambers, Bishopsgate Street Without, E.C.

VAUGHAN ENGINEERING INSTALLATIONS.—Registered on June 11th, with a capital of £5,000, to acquire the business carried on at 298-300 Goswell Road, London, as Vaughan & Cook, Ltd., and to carry on the business of electric light engineers, electricians, manufacturers of motors batteries and electroliers, &c. Registered office, 298 and 300 Goswell Road, Finsbury, E.C.

BRITISH VITRITE WORKS (SWAN'S PATENTS).—This company was registered on June 17th, with a capital of £30,000 in £1 shares, to adopt an agreement with Swan's Patents, Ltd., and to carry on the business of manufacturers of and dealers in nitrite and other caps or bases for incandescent electric lamps, electric lamps and fittings, &c. First directors, B. M. Drake and W. A. Turquand. Registered office, Broad Street House, New Broad Street, E.C.

POWER TRANSMISSION SYNDICATE.—This company was registered on June 18th, with a capital of £40,000 in 39,500 cumulative preferred participating ordinary shares of £1 each, and 10,000 deferred shares of 1s. each, to adopt an agreement with E. Hess Remanda, and to carry on the business of electricians, generators, accumulators, distributors, and suppliers of electricity, engineers, proprietors of tramways and railways, omnibuses, motor cabs, cars, carriages, vans, and conveyances of all kinds, &c.

MAXWELL'S (DUNDEE).—Registered in Edinburgh on June 14th, with a capital of £25,000 in £1 shares, to purchase the business, &c., of Maxwell, Son & Co., electrical, mechanical, and motor engineers and brassfounders, of 26 St. Andrew Street, Dundee.

THE BREMER FLAME ARC LAMP PATENT

Hearing of the Action for Infringement

THE hearing of the action brought by the British Westinghouse Co. against Mr. G. Braulik for alleged infringement of the Bremer flame arc lamp patent, which commenced on Tuesday, June 22nd, was continued until Thursday last week, and was resumed again and concluded on Monday.

From the report of the first day's (Tuesday's) proceedings given in our last issue, it will be remembered that Mr. Braulik denies infringement, and disputes the validity of the patent on the ground of anticipation.

The patent in question is No 18,786 of 1902, granted to H. Bremer, and covers means for producing a lateral to-and-fro movement of one or both carbons in arc lamps of the converging

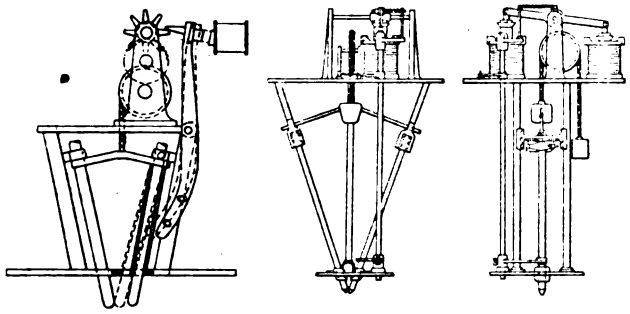

FIG. 1.—THE THREE FIGURES OF THE BREMER PATENT No. 18,786/02.

carbon pattern, independent of the downward feeding motion. Two alternative mechanisms are described in the specification, and the accompanying figures are reproduced below in Fig. 1. The first mechanism consists of an arm which bears against one carbon. An armature attached to the upper end is attracted by an electromagnet, and this end also holds the detent, which engages with a star-wheel geared to the feeding-cord drum. If the arc lengthens, the armature is attracted to the magnet, and the swinging carbon pushed towards the other carbon, and this action is continued until the star-wheel is released. Feeding then takes place. In the second mechanism, the swinging carbon is moved by means of a loose collar near its burning end, this movement being controlled by a vertical shaft which is given a rotary motion by means of the differential action of shunt and series coils. The claim and the disclaiming note were given in our issue of last week.

Of the thirteen patents cited by Mr. Braulik as anticipations of the Bremer patent, those of Graham and Crosby are the two chiefly relied upon. The following are reproductions of the most important figures of these two patents and brief decriptions of the mechanisms.

Fig. 2 represents two figures from the specification of the U.S.A. Patent No. 268,218 granted to A. Graham in 1882,

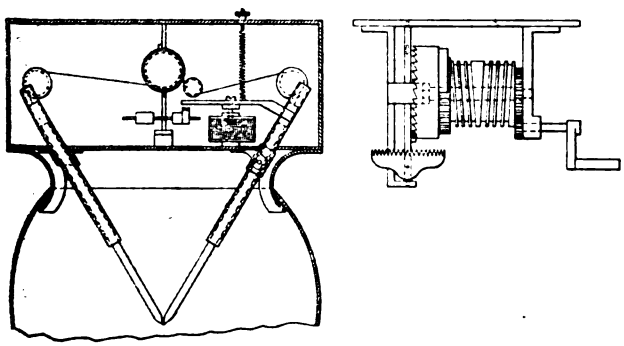

FIG. 2.—GRAHAM'S CONVERGING CARBON LAMP. U.S.A. PATENT No. 268,218/82.

depicting an arc lamp with inclined carbons, one of which is pivotted and rocked by means of a lever. The armature on this lever is pulled downwards by the series magnet against the action of the spring on switching on, and the end of the lever comes between the teeth of the comb of the Dutch-clock escapement, thus arresting the feed. When the current decreases, the lever is lifted by the spring and feeding is permitted. It is evident that before feeding takes place the pivotted carbon is moved towards the fixed carbon, but the question at issue is whether or not a to-and-fro adjustment of this carbon is effected, or was even intended.

Fig. 3 shows the two figures accompanying the Crosby U.S.A. specification, No. 553,335 of 1896. In this mechanism either one or both carbons may be pivotted, and each carbon passes through a ring near its lower end, supported by a steel spring. The carbons feed down by gravity, but are held up by the

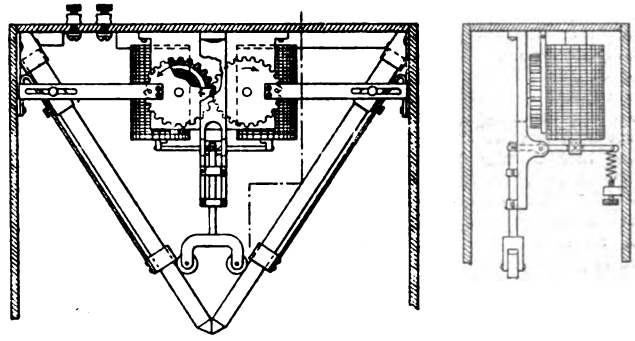

FIG. 3.—CROSBY'S CONVERGING CARBON LAMP. U.S.A. PATENT No. 553,335/96.

rollers, which press against them. The rollers are fixed to a yoke controlled by the electromagnets, and when the current is switched on, the rollers descend and separate the carbons. As the current decreases, the rollers ascend, allowing the carbons to come together. At a certain point, however, the pressure of the rollers is so slight that the carbons slip down, and immediately the rollers descend again. As in the Graham patent, the question at issue is whether or not a to-and-fro adjustment takes place.

On Tuesday, June 22nd, Mr. A. J. WALTER, K.C., opened the case for the Westinghouse Co. by explaining the scope of the patent, and Mr. J. SWINBURNE was called to give evidence as to the value of the patent, and the extent of the infringement, as reported in our last issue. In concluding the cross-examination of Mr. Swinburne on Wednesday, June 23rd, Mr. Bousfield called his attention to an illustration and description of the Serrin lamp published in a Paper by Prof. S. P. Thompson in 1889. This, Mr. Swinburne admitted, had a to-and-fro adjusting movement independent of the feed, but it was a vertical carbon lamp. Bremer's invention was the application of this movement to inclined carbon lamps. He admitted that there was an oblique movement of the armature in Graham's lamp, so that the armature would probably not touch the magnet core at all; but he insisted that although it might float, that effect was not intended by Graham.

Re-examined by Mr. Walter, Mr. Swinburne asserted that there was no mention in Graham's specification of a regulating movement being effected, while the knife was in the escapement teeth. He knew of no converging carbon lamp previous to Bremer's which had a floating adjustment interconnected with the feed so as to retard it until the adjustment had taken place. A cardboard model of Graham's lamp, showing that a floating action was possible, which had been made by Prof. S. P. Thompson, was produced in court, but Mr. Swinburne asserted that although there would be no difficulty to make a lamp with a floating adjustment from Graham's specification, knowing of Bremer's invention, it could not be done from Graham's description and figure only. The five features enumerated by Mr. Walter on Tuesday were, he said, in both the Bremer lamp and Mr. Braulik's "Eclipse" lamp, and the adjustment was obtained substantially in the same manner in both. The only differences were well-known alternatives for certain mechanical details.

Mr. DUGALD CLERK, examined by Mr. Walter, said that there was room for invention previous to Bremer's patent, as all the former lamps with to-and-fro adjustment, such as the Brockie-Pell and Serrin lamps had vertical carbons, and an adjustment in the direction of feed. Further, the electromagnet had other work to do besides adjusting the carbons, namely, lifting one or both carbons and a system of levers. It was important that the adjusting magnet should have little work to do, so that the adjustment should be delicate. Mr. Braulik's lamp contained all the five features covered by the Bremer claim.

[Mr. JUSTICE JOYCE here pointed out that the Westinghouse Co. could only rely on the claim, irrespective of the figures and specification, as the words "substantially as described" were omitted from the claim.] Mr. Dugald Clerk affirmed that there was nothing whatever in Graham's specification about a floating adjustment; the carbon was swung to strike the arc, but it was

Digitized by Google

an instantaneous movement. When the carbons burnt down, the balance would be disturbed, but in Bremer's lamp this difficulty was overcome by swinging the carbon by a device acting near the lower end. The Crosby specification did not, he said, contain Bremer's invention, as it was impossible for the rollers to push the carbons apart without stroking them down at the same time; the adjustment, therefore, was not independent of the feed.

Cross-examined by Mr. Bousfield, Mr. Dugald Clerk admitted that if the Bremer lamp had been made exactly as shown in the first of the three drawings, it would not work, as the tube shown surrounding the swinging carbon would get in the way. He contended that Graham had applied a swinging motion to a converging carbon lamp only for striking the arc. The parts of the mechanisms in both the Bremer and the "Eclipse" lamps were old, but the combination of these parts was the same in both, and that was, he said, protected by Bremer's patent.

Mr. H. E. MOUL, the technical manager of the Union Electric Co., Ltd., was then examined by Mr. Walter as to the importance of the Bremer patent. Since 1905 some 14,000 lamps had, he said, been constructed in accordance with the invention and put upon the English market by Messrs. Körting & Mathieson, whose agents were the Union Electric Co., and who were licensees under the patent. Eleven to twelve out of every 16 flame arc lamps other than those of his own firm in use in this country contained the Bremer principle.

Cross-examined by Mr. J. HUNTER GRAY, Mr. Moul stated that he had considered that the Högner patent covered the Bremer principle, and that they had sold flame arc lamps with the Bremer principle under the Högner patent previous to the acquirement of a licence under the Bremer patent in 1906. It would be quite possible to invent a converging carbon flame arc lamp with quite a different principle to that of Bremer, which, with good design and workmanship, would work equally well. The Bremer principle was not essential. He had helped to make the model of the Bremer lamp. In his opinion, the Bremer patent contributed most to the commercial success of the flame arc lamps sold by his firm.

Re-examined by Mr. Walter, Mr. Moul stated that he had no difficulty in constructing a working model from the figures of the Bremer specification.

On Thursday, Mr. J. HUNTER GRAY opened the case for Mr. Braulik by pointing out that the floating movement was not mentioned in the Bremer specification. It was common knowledge before 1902 that a to-and-fro movement before actual feeding was advantageous. He submitted that there was not subject-matter for a patent in Bremer's specification, as the principle was not novel.

Prof. S. P. THOMPSON, examined by Mr. Gray, then gave evidence to the effect that of the many types of arc lamps known in 1882, the year of Graham's patent, a large percentage had a retractile adjusting motion after striking, so that the carbons approached before feeding took place. There was nothing new whatever in what Bremer claimed. Questioned as to whether there was anything new in either the figures or the specification, he stated that the only novel feature was that iron cheeks were placed at the top of the solenoids (see Fig. 1), and collars round the cores. These would increase the pull on the cores at each extreme position of the rocking lever, tending to hold the latter down, and would thus tend to prevent a floating action. Although the disclaiming note limited the invention to lamps with firmly clipped electrodes, the specification said nothing about this. With regard to the device acting near the lower end, the first of Bremer's figures did not confirm this statement, as the lever would act on the upper end of the carbon after the lamp had burnt for some time. This feature had no important practical value. The lamp described and illustrated in Graham's specification (see Fig. 2) corresponded, he said, with every word of the Bremer claim. It was impossible for the armature in Graham's mechanism to be held down. On the other hand, the armature of Bremer's mechanism (see Fig. 1) came in contact with the magnet core and would stick. If Graham's armature did not float, the mechanism would not achieve what was intended. The action of the Crosby lamp was also in accordance with Bremer's claim, and there was nothing novel in the latter. With regard to the alleged infringement, there was no part of the "Eclipse" lamp which required the aid of Bremer's specification for its construction.

Cross-examined by Mr. Walter, Prof. Thompson agreed that there was no practical converging carbon lamp until flame carbons were introduced in 1900, and that, owing to the variation of the arc resistance caused by the presence of the salts, the regulation became much more important with the introduction of these carbons. He also agreed that there was no successful converging carbon flame lamp on the market previous to the date of Bremer's patent. The capacity for an adjusting movement was suggested in Bremer's specification, but the first figure did not support this. Questioned as to Graham's specification, he admitted that no mention was made of a backward and forward motion. [It was here pointed out that the question as to whether there was a floating action or not in the Graham and Crosby lamps could not be settled by the models produced in court, as slight differences in workmanship and adjustment would seriously affect the matter.] Prof. Thompson agreed that if the rollers of the Crosby mechanism were not smooth, they would stroke the carbons down when they descended to separate them, but insisted that Crosby did not intend that they should do so. They would merely separate the carbons if they were quite smooth. Questioned as to the work to be done by the magnet in the Serrin lamp, he pointed out that it had only to overcome the difference between the weight of the mechanism and the force of a spring.

Re-examined by Mr. Gray, Prof. Thompson asserted that there was no substantial difference between the force exerted by the magnets in the Serrin, Graham, and Bremer lamps. There was nothing in the Graham specification to imply an instantaneous pull off of the armature; a to-and-fro movement of the lever when in the teeth would necessarily take place, especially with a solenoid. He thought that if flame carbons had been on the market before 1900, there would have been no difficulty in making a flame arc lamp with Graham's adjustment without knowledge of Bremer's patent.

Prof. J. D. CORMAC was then examined by Mr. Gray, and his remarks confirmed those of Prof. Thompson. Cross-examined by Mr. Walter, he said that he knew of no satisfactory converging carbon lamp being on the market before 1902. A horizontal adjustment was, he thought, implied by the language used by Graham.

After a brief re-examination of this witness by Mr. Gray, the hearing was adjourned until Monday.

On Monday, Mr. BOUSFIELD continued the statement of the case for Mr. Braulik, asserting that he was going to rely chiefly on anticipation, with particular reference to the Graham specification. He did not wish to drop his other points altogether, though. With regard to disconformity, under the new Patents Act there might be something in the complete specification which was quite different to what was described in the provisional without there being any disconformity, so long as the addition was novel and was invented by the patentee between the date of the provisional and the complete specifications. In this case, however, the addition had been described in Högner's specification filed during this period, and was therefore not novel. The patent was, he thought, for the idea expressed in the claim only, irrespective of the figures or of any particular device, and if the Westinghouse Co. were content to rely on this, there was no need to trouble about the differences between the provisional and the complete specifications. From Mr. Swinburne's evidence, the disclaiming note described features which were distinctions rather than differences, and had therefore no effect. Mr. Bousfield then repeated the arguments for anticipation, and then turned to the question of subject matter. A patent could not, he said, be granted for an idea, but only for the means of applying an idea. The idea in this case was old, and the alleged invention consisted in applying it for an analogous purpose to that for which it had been used. He therefore claimed that, apart from anticipation, there was no subject matter for a patent.

Mr. WALTER then briefly stated the case for the Westinghouse Co. He pointed out that according to the claim, the patent was not for an idea, but for a lamp embodying an idea, and that descriptions and figures showing how that idea could be carried out were given in the specification. It had been asserted that these descriptions did not represent commercially practicable lamps, but, he said, patent drawings were not intended to be working drawings. A patent had nothing to do with commercial utility. With regard to anticipation, the specifications quoted admittedly contained no reference in words to a floating action, although it was affirmed that the lamps described would work thus. Mr. Swinburne and Mr. Dugald Clerk had stated that they did not, and no evidence had been brought by Mr. Braulik to show that the Graham lamp did, as neither of Mr. Braulik's expert witnesses had seen the model working. Even if there was a floating adjustment in the case of the Crosby lamp, it had been admitted that there was a slight downward feed at the same time, and the adjustment was therefore not independent of the feed as claimed by Bremer.

Mr. Justice Joyce has reserved judgment.

Telegraph Traffic and Movements of Cable Ships.—There are no further cable breakdowns to report. The Trinidad-Demerara cable is still down, and the wireless installation apparently not yet working. The French company's section to French Guiana and Brazil is also still down. The line between Bagdad and Bassorah was disturbed on June 22nd, but was restored to working order on the 25th inst. Communication between Rome and Constantinople was interrupted on June 23rd, but was restored on the following day. Telegraphic communication with Tauris and the Province of Azerbaidjan *via* Djoulfa, as well as the line between Teheran and Astrabad, were restored on 25th inst. The cable steamer *Minia* was at Halifax, Nova Scotia, on June 1st, and left again for a repair on the 3rd ult., somewhere between St. Pierre and North Sydney, and returned to port on the 8th ult. The French cable steamer *Contie Amiral Caubet* also left Halifax on May 21st for a repair on the Grand Banks of Newfoundland. The cable steamer *Mackay-Bennett* is still in English waters.

CATALOGUES AND PAMPHLETS, &c., RECEIVED

[READERS APPLYING TO ANY OF THE UNDER-MENTIONED FIRMS FOR COPIES OF THE CATALOGUES OR PAMPHLETS REFERRED TO ARE REQUESTED TO MENTION "ELECTRICAL ENGINEERING."]

EXCESS SPEED ALARM.—A pamphlet from Messrs. Crompton & Co. (Salisbury House, London Wall, E.C.) describes the Hounsfield patent excess speed alarm for automobiles, which has been designed in view of the proposal of the Chief Commissioner of the Metropolitan Police to require the attachment to all public vehicles of a device whereby an audible signal is given whenever the legal limit of speed is exceeded. The device consists of a gong or bell mounted on some part of the car where the noise which it makes can be heard both by the driver and by persons passing. Inside the bell is a spindle running in ball bearings and driven in such a way that the speed of this spindle always bears a definite relation to the speed of the car. Mounted on the spindle is a lever pivoted, so as to fly outwards when the car accelerates, but restrained by a spiral spring, the tension of which can be adjusted. This pivoted lever is provided with a hammer which strikes projections on the bell and causes it to give an audible and continuous indication when the car attains a speed above the limit laid down in the regulations.

CALENDAR.—Messrs. W. T. Glover & Co., Ltd. (Trafford Park, Manchester), have issued their well-known calendar for the ensuing twelve months, in which each daily sheet is either embellished with a humorous illustration or provided with some useful items of technical information.

METAL FILAMENT LAMPS.—A new pamphlet from the British Thomson-Houston Co. (Rugby) calls attention to several new sizes of B.T.-H. tungsten lamps. Among the most useful of these are a 20-c.p. (25 watt) 100-volt lamp, and a new lamp for 200 to 260 volts of 32 c.p. taking 45 watts, which will be ready for delivery during August.

CARBON BRUSHES.—A list from Messrs. W. Geipel & Co. (Vulcan Works, St. Thomas Street, London, S.E.) deals with graphitic carbon brushes manufactured by the firm of F. Herion & Co., for whom Messrs. W. Geipel & Co. are agents in this country. Illustrations are given of a number of brushes, many of which are partly copper-plated, and carbon plugs and plates for switch contacts are also dealt with.

METAL FILAMENT AND OTHER HIGH-EFFICIENCY LAMPS.—Two recent leaflets from the Electrical Co., Ltd. (121 Charing Cross Road, London, W.C.) deal respectively with a new size of "Aegma" lamp, giving 25 c.p. on 200- to 260-volt circuits, which is, we believe, the smallest high-voltage metal filament lamp on the market, and the new 30-c.p. high-efficiency lamp on the Nernst principle, which is made for 200- to 250-volt circuits.

ELECTRICAL ACCESSORIES.—The Sun Electrical Co., Ltd. (118 Charing Cross Road, London, W.C.), have sent us a leaflet illustrating a new adjustable adapter by which metal filament lamps can be made to hang vertically from any electrolier or bracket, and some attractive new forms of electric cigar-lighters, one of which takes the form of a bronze monkey holding the heating plug in its arms.

ELECTRIC LIFTS.—A very handsome new catalogue of electric lifts has been issued by Messrs. R. Waygood & Co., Ltd. (Falmouth Street, London, S.E.). This contains reproductions of photographs of a number of actual lifts in their ornamental architectural surroundings, and particulars of the methods of driving adopted, including a drum-winding machine and a special method of driving with "V" sheave. Systems of control described include those with a pilot switch in the cage, and fully automatic or semi-automatic push-button systems, as well as the simplest and cheapest form of controller worked by a hand rope. All these systems are applicable to alternating current as well as direct current. Illustrations are given of several varieties of goods lifts as well as passenger lifts.

STORAGE BATTERIES.—The Hart Accumulator Co., Ltd. (Stratford, E.), are issuing, in addition to their ordinary 1909 catalogue of accumulators, a very convenient pocket catalogue containing full information of the principle types of cell of their manufacture.

FACTORY SITES.—A recent addition to the advertising literature of the West Ham Corporation Electricity Department is an illustrated circular giving a number of manufacturing and other concerns which have recently established themselves in West Ham, and take power from the Corporation.

INDIRECT LIGHTING.—Mr. G. Braulik (8 Lambeth Hill, E.C.) is sending out a leaflet describing a series of new "Eclipse" fittings for obtaining indirect lighting with metal filament lamps. The lamps are hung within a hemispherical bowl, with an inner reflecting surface, suspended by three chains; a convex upper reflector is used in some cases as well.

A NEW CHAIN ADJUSTER.—A pamphlet from Weldless Chains, Ltd. (Gartsherrie, Coatbridge), describes an ingeniously designed steel link with removable pins, which can be utilised for shortening, joining, or adjusting the length of chains and slings.

BOILER COVERINGS.—A booklet from Newall's Insulation Co., Ltd. (Newcastle-on-Tyne), describes several forms of heat-insulating materials for covering boilers, steam pipes, &c. Newall's magnesia covering consists of an intimate mixture of hydrated carbonate of magnesia and asbestos fibres, and is used to a very large extent in British and foreign navies and mercantile marines. This is made up in a number of forms, including special-shaped blocks and slabs, for covering steam turbines. Numerous views are given of steamships and machinery where these coverings are used.

AN ALTERNATING-CURRENT DIRECTION INDICATOR

IN view of some remarks recently made in the discussion on Mr. Rider's Paper on the "Electrical System of the L.C.C. Tramways," at the Institution of Electrical Engineers, relating to the uncertainty of the working of certain reverse-current A.C. relays, Messrs. Cowans, Ltd., have called our attention to a device for use in cases where several alternators are worked in parallel, for indicating when a generator is supplying current to, or receiving current from, the bus-bars. In America, an instrument of this description has been in use for some time, a relay closing a switch and thereby lighting a red lamp when the generator is receiving a motoring current. Messrs. Cowans' instrument effects the same result, but without the use of any switch, its action being purely inductive. It is arranged to indicate by means of a green lamp when a generator is generating, and by means of a red lamp when a generator is motoring. There is nothing to get out of order, and, as its only function is to indicate, no switches are tripped when it would be desirable that they should remain closed. The indication of an ammeter is misleading and not sufficiently noticeable, but the lighting up of a red lamp is seen at a glance and its indication is unmistakable.

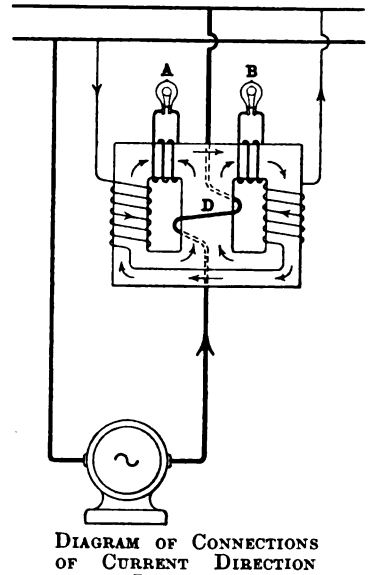

DIAGRAM OF CONNECTIONS OF CURRENT DIRECTION INDICATOR.

A diagram showing the action of the apparatus is shown herewith. *A* and *B* are respectively red and green lamps connected across independent secondary windings. The combined effect of the series and shunt windings is to light the green lamp *B* when the series is in phase with the shunt, *i.e.*, when the generator is feeding current into the bus-bars, and to extinguish the green lamp and light the red lamp on a reversal of the series current relatively to the E.M.F.

THE NEW UNIT OF INTERNATIONAL CANDLE POWER

A PAPER entitled "The Proposed International Unit of Candle-Power" was read by Mr. C. C. Paterson at a meeting of the Physical Society on June 11th. The Paper discusses the units of candle-power at present officially accepted in Great Britain, France, the United States of America, and Germany. The numerous intercomparisons which have taken place during the past five years between these units show that the candle, as interpreted in France, Great Britain, and the United States respectively, has practically the same value in the three countries. The authorities in the gas and electric interests in the United States were prepared to adjust their units of candle-power to bring them to a single value which is to be the same as the British and French units. The Paper gives the results of comparisons showing that within the limits of experimental error the British and French units are identical. The change involved in the unit at present maintained at the Bureau of Standards, Washington, is shown to be 1·6 per cent. The agreement thus established forms the subject of an official memorandum from the National Physical Laboratory (with the concurrence of the Metropolitan Gas Referees), the Bureau of Standards, Washington, and the Laboratoire Centrale, Paris. The proposal to call the common unit of light to be maintained jointly by the National Standardising Laboratories of America, France, and Great Britain the "International Candle" has been submitted to the International Electrotechnical Commission, and through it to all the countries of the world which are represented on that Commission. The Hefner unit is shown to be almost exactly $\frac{9}{10}$ths of the new unit. The comparisons between the units have been made by two methods: (1) The direct comparisons of the flame

Digitized by Google

standards in France, Germany, and Great Britain. (2) Through the medium of electric sub-standards which have had values assigned to them in the National Laboratories of the four countries. The agreement between the ratio values by the two methods is very close, and is shown by a table giving the results of the various comparisons which have been made.

In the course of the discussion Dr. J. A. FLEMING said that he greatly regretted that the National Physical Laboratory authorities had acquiesced in the adoption of a flame standard of light with all its difficulties and variabilities. Influenced as they are by atmospheric pressure, moisture, CO_2, height of flame, composition of fuel, and number of persons in the photometric room, these flame standards could not possibly be considered as a final solution of the problem of obtaining a primary standard of light. What was really required was the concrete realisation of a permanent primary standard, which would be the standard of reference for secondary standards like the large-bulb glow-lamp standards, which he (Dr. Fleming) had introduced seven years ago. Dr. Fleming remarked Prof. Petavel had shown that with suitable precautions the unit of illumination could be reproduced within 1 per cent. by means of the molten platinum standard.

ELECTROMETALLURGY AND ELECTRO-CHEMISTRY

AT a meeting of the Faraday Society held on June 15th, Mr. E. R. Taylor read a Paper on "The National and International Conservation of Water Power." It was pointed out that the water-power capacity of the United States, with proper conservation, is not less than 150 million h.p., without considering the storage capacity of small streams and brooks. The annual stream flow is 70 million cub. ft., of which less than 1 per cent. is retained and utilised for municipal supply and similar purposes, less than 2 per cent. is used for irrigation, 5 per cent. for navigation, and less than 5 per cent. for power purposes. From 85 to 95 per cent. is wasted in the floods. This illustrates the kind of waste which is taking place all over the world, and the author described typical examples of such wasted resources. The impounding of flood-waters in the uplands with its accompanying afforestation of the hills was recommended, and the simultaneous conservation of sources of power, which are vast in the aggregate and are almost entirely uncontrolled and untapped. Electrochemical industries in particular would benefit by the creation of cheap and abundant sources of power, on which, in fact, their very existence depends. The necessity for this problem being considered internationally by all the civilised nations of the world was strongly urged. In the discussion, Mr. W. Murray Morrison spoke of the good which had followed the development of the power schemes at Foyers and Loch Leven, both of which were now the centres of a flourishing industry and population.

Mr. W. Fielding contributed a Paper on "The Formation of Silicon Sulphide in the Desulphurisation of Iron." In the refining of steel in the electric furnace a very complete desulphurisation of the metal can be effected, and this action is facilitated by the addition of a charge of ferrosilicon. He believed this to be due to the formation of silicon sulphide SiS_2, which was then volatilised. Professor Huntington thought it more probable that a silico-sulphide of iron was the substance formed and volatilised.

"A Contribution to the Study of Electric Furnaces as Applied to the Manufacture of Iron and Steel," by Charles A. Keller, was then read. The author described the various classes of conducting hearths, classifying them as follows:—(1) Those made entirely of metal, water cooled. These have no industrial value. (2) Those consisting of one or more metallic poles (or graphite protected by metal) embedded in a non-carbonising masonry. The original furnace of Siemens and the furnaces of the Girod and Borchers are of this type. (3) Furnaces consisting of a hearth of refractory material, such as magnesia or silica, rendered conducting by a carboniferous substance. The Firminy furnace, of which at present only a small example has been constructed, is of this type. (4) Furnaces made up of a mixed conducting material; this is the type devised by the author. The hearth consists of "reinforced clay," made up of iron bars 25 to 30 mm. in diameter, placed vertically 25 to 30 mm. apart, and packed solid with magnesia. When cold, of course only the bars are conducting, but when in operation the hearth is conductive over its whole section, and the electrical resistance is very small. The mechanical resistance of such a hearth to the subsistence of the metallic bath is very considerable, and the author states that the bottom of the furnace is absolutely indeformable. For example, the hearth of a 1,500 kg. furnace, examined after many months' service, was in exactly the same condition as when it was started. The author considers that the furnaces with conducting hearths are, from a metallurgical point of view, better than those with vertical electrodes in series, because the current traverses the whole mass of metal, and thus renders it more homogeneous. Moreover, the furnace is mechanically more simple. On the other hand, the series electrode furnace is of simpler construction, and only half the current density is necessary for the same output, thus economising electrical connections. The furnace with conducting hearth requires careful design to minimise self-induction and increase the power factor, and a low frequency, say about 20, should be employed. With this frequency a power factor of 0·9 should be obtained with a 1,000-kw. furnace.

A Paper by Gustave Gin was also contributed on "Automatically Circulating Furnaces of the Gin type for the Electrical Production of Steel." Induction furnaces were described in which the molten material is in continual circulation, thus causing a better distribution of heat and of the purifying reactions than in the ordinary induction furnaces. The furnaces are composed of two crucibles communicating by inclined channels, the whole forming a closed circuit in which the heat generated causes a general circulation. Each portion of the molten mass comes rapidly into contact with the oxidising slag, and the high temperature obtained does not cause the "pinch" effect in the heating channels. In this type of furnace it is claimed that the ohmic resistance of the circuit can be increased with a corresponding alteration of the self-induction, thus allowing furnaces with a high power factor to be constructed, and yet generators and transformers of normal frequency and size to be employed. An electrode furnace was also described, in which the same system of automatic circulation is applied, by cross-connecting the separate crucibles into which the electrodes dip by means of inclined channels sloping in opposite directions. In conclusion, the author described a combined electrode and induction furnace similarly arranged for automatic circulation of the fluid steel.

At the annual general meeting held on Tuesday, the annual report was presented, which showed that satisfactory progress had been made in the past year, although the membership roll was not so large as could be wished. Dr. R. Beckett Denison read a Paper on "Researches on the Relative Rates of Migration of Ions in Aqueous Solution." This Paper, which was of theoretical interest, dealt with the transport numbers of the chlorides, bromides, and iodides of sodium, potassium, ammonium, rubidium, caesium, magnesium, calcium, strontium, and barium. Dr. H. J. S. Sand contributed a Paper on "Apparatus for the Rapid Electroanalytical Separation of Metals." In this Paper he describes an improved apparatus for rotating the electrodes, and also a new form of potentiometer for employment with graded potentials. The arrangement is so designed that by depressing a key it will allow the potential difference between the anode and cathode to be read directly. Mr. Samuel Field also contributed a Paper on the "Conditions which Determine the Composition of Electro-deposited Alloys."

The Electron.—The May issue of the magazine conducted by the employees of Messrs. Siemens Bros.' Dynamo Works at Stafford contains, amongst items of engineering interest, the second part of a Paper by Mr. C. A. Ablett on "Rolling Mills," and a very full, illustrated description of the works of the Bristol Corporation Electrical Supply Undertaking, by C. R. Palairet, where a quantity of Siemens plant and apparatus of various descriptions is at work, ranging from the old alternators in the Temple Back Station to the fine new high-tension switchboard at Avonbank. There is also an article on large gas engines, by Mr. E. A. Watson, and several contributions on more general subjects.

Wind Turbines for Electricity Supply.—Among the exhibits at the Royal Agricultural Show, now being held at Gloucester, is an interesting plant for electricity supply from wind power, shown by Messrs. J. C. Child & Co., Ltd. (Hawthorn Road, Willesden Green). The firm are exhibiting a 24 ft. diameter plant, which consists of a wind turbine upon a steel tower 60 ft. high, with vertical shaft driving a Morris Hawkins variable-speed, 50-volt generator, placed vertically, and charging a 28-cell Pritchett & Gold battery, having a discharge capacity of 450 ampere hours. From this plant is lighted the show cottage of the "Country Gentleman's Association," 200 yards distant, and the current is supplied for working an electric grill there. The storage battery is divided into two parts, and by means of a special arrangement, 50 volts can be used for working the cooking apparatus and other machines exhibited, 25 volts for the lighting, thus making use of metallic filament lamps. The firm also show an electric oven, in which special attention has been given to insulation. It differs from all other ovens in that it has a polished marble top and oak sides, and looks more like a piece of dining-room furniture than the conventional oven. Very little external heat is given off, so that great economy of current consumption is obtained. The plant is also supplying the energy for running two electric grills, saucepan, and steamers, radiator, kettles, fans, irons, &c., all by the Phœnix Electric Heating Co., and also a deep well pump by Messrs. Le Grand & Sutcliffe, a butter churn and cream separator by the Dairy Outfit Co., and a circular saw of special design, suited for wind turbine driving. The generator has a special switch, by means of which it can be run as a variable speed motor for driving any of the above machines when there is no wind, taking current from the battery. This plant, in localities where the wind averages about eight miles an hour, will produce about 3,000 units per annum.

HIGH-EFFICIENCY CARBON FILAMENT LAMP

THE following are some particulars of an high-efficiency carbon filament lamp which has been put on the market in Germany. The lamp is the invention of Herr R. Hopfelt, and is sold under the name of the "Tuba" lamp.

The carbon filament, which is especially prepared, is enclosed in a U-shaped tube, and the tube contains a drop of mercury and some nitrogen at a pressure of about 1 mm. When current is switched on, some of the mercury is evaporated by the heat produced by the filament. Owing to the presence of the mixture of mercury-vapour and nitrogen which is formed, the filament can be run at a much higher efficiency than is advisable with the ordinary carbon filament lamp without any fear of the tube blackening or the filament burning out prematurely. Originally the tube was enclosed in an outer globe, so as to make a stronger lamp and to facilitate the attachment of the cap, but this was, owing to the higher temperature attained by the tube, found to shorten the life of the filament so much that the outer globe was discarded.

The accompanying figure shows the lamp in its present form. Tubular glass extensions are fused on to the U-tube, and these

"TUBA" HIGH-EFFICIENCY CARBON FILAMENT LAMP.

are fixed into the cap, as if the tube itself is carried into the cap, it gets too hot, and the gaseous mixture is affected. When new, the lamps have an efficiency of 1·8 watts per Hefner candle, or 2·05 watts per British candle; but towards the end of their life, the efficiency rises to 1·5 watts per Hefner candle. The lamps burn in any position, but not satisfactorily when the U-tube is inverted, as then the filament is not near enough to the mercury. It should be mentioned that the candle-power is temporarily increased if the pressure of the mercury-vapour is increased by causing the tube to heat up, but the life of the filament is shortened. The mercury-vapour does not glow itself, but, owing to the high temperature of the filament, a whiter light than that from the ordinary carbon filament lamp is emitted. It has been found that the burning life of the lamp is longer when it is burnt intermittently, and that this is due to the fact that whereas a certain amount of free oxygen collects in the tube after burning (and especially if the tube heats up), this is absorbed by the mercury when in a cold state. Thus, when running continuously, the burning life is approximately 500 hours, but when the lamp is used intermittently as in ordinary working, the life is between 600 and 800 hours.

The 100 to 150-volt lamps are put on the market in two sizes, namely, 25 and 40-c.p., at a price of 1 m. 50 pf. (1s. 6d.), and a 200 to 250-volt, 50-c.p. lamp is sold at 2 m. (2s.). An efficiency of between 1·6 and 1·8 watts per candle is guaranteed, and the lamps are suitable for both continuous and alternating current.

New Argentine Cable.—It is reported that the Argentine Government has concluded an agreement with the Western Telegraph Co., in regard to the laying of a cable from Argentine to Ascension, to connect the Republic with Europe and North America, independently of Brazil or Chili. It is said that the agreement gives the Western Telegraph Co. a preferential right for 25 years to the laying of all cables between Argentine and other countries, but as Congress has yet to sanction the agreement, it is expected that this clause will be modified.

THE BRUSSELS INTERNATIONAL EXHIBITION, 1910

ON a previous occasion (see ELECTRICAL ENGINEERING, April 8th, page 329) we have referred to the encouragement to British exhibitors in foreign international exhibitions, which is being given by the Royal Commission, presided over by the Prince of Wales, through the Exhibitions Branch of the Board of Trade. We have now received some further particulars regarding the arrangements. The British Government has secured one of the most prominent positions in all the exhibition for its section. The space amounts to 203,140 sq. ft., of which 150,640 sq. ft. are in the Industrial Hall, and 52,500 sq. ft. in the Machinery Hall. The main gallery running through the British section is 510 ft. long by 98 ft. wide and there are four other parallel galleries 56 ft. wide. In the Machinery Hall the portion allotted to Great Britain occupies the centre of the hall, and has easy access to the electric, steam, water, and gas mains from which power can be obtained for showing all classes of machinery in motion. It is also intersected by three lines of rails which communicate directly with the Belgian State Railway system. The Royal Commission Officials will undertake the entire handling of the exhibitors' goods within the Exhibition; not only unloading and displaying on the space reserved, but storing all empty packing cases and reloading at close of Exhibition. With the exception of machinery and rolling stock, the exhibits of Great Britain will be grouped so as to form a complete national display of the various manufactures and products; and with a view to uniformity, the Royal Commission will undertake the entire decoration of the British section, and provide all show cases, stands, platforms, and screens required by each individual exhibitor, without further charge. The scheme provided for a uniform style of decoration and a standard design of showcase, samples of which may be seen at the offices of the Commission, 30 Broadway, Westminster. The charges for space vary from 2s. 6d. to 6s. a square foot, according as platforms, cases, &c., are required or not.

The Commission will also defray fifty per cent. of the charges made for the supply of steam, gas, and electricity, when used for showing machinery producing finished articles, or illustrating a process of manufacture. Exhibitors requiring foundations or shafting for machinery must provide them at their own cost, but can, upon sending to the offices of the Royal Commission drawings with metric measurements, have estimates obtained for them from Belgian contractors, and the work carried out under the superintendence of a competent engineer employed by the Royal Commission. Crane power will be provided up to seven tons weight free of charge, and special facilities for handling heavier weights can also be secured if application be made. Assistance will also be given in a variety of other ways.

The chairman of the Royal Commission is Lord Lytton, and the vice-chairman Sir Swire Smith. The interests of machinery and electricity are well represented among the commissioners, who include:—For machinery: Mr. W. J. Crossley, M.P., chairman of Crossley Bros.; Mr. John McLaren (J. & H. McLaren), president of the Agricultural Engineers' Association; Sir William Mather; and Mr. T. Hurry Riches, president of the Institution of Mechanical Engineers. For electricity: Dr. R. T. Glazebrook, F.R.S., director of the National Physical Laboratory, and ex-president of the Institution of Electrical Engineers; Mr. Guglielmo Marconi (managing director, Marconi International Marine Communication Co.).

The Machinery and Electricity Committee has the following co-opted members of the Commission:—Mr. E. B. Ellington (London Hydraulic Power Co.), Mr. W. H. Allen (Allen & Sons, Bedford), Mr. Mark Robinson, Mr. H. F. Donaldson (Chief Superintendent, Ordnance Factory, Woolwich), Mr. J. H. Wicksteed (Joshua Buckton & Sons), Mr. R. H. Fowler (Fowler & Co., Leeds), Mr. W. Duddell, F.R.S., Mr. H. J. Brackenbury (Armstrong, Whitworth & Co.), Mr. J. E. Kingsbury, Mr. W. H. Patchell, Mr. W. M. Mordey, Sir John Gavey, C.B., Col. W. Shanks, V.D., Mr. W. D. Ford-Smith, Mr. Allen Baker, M.P., Mr. Frank E. Musgrave, Mr. Arthur Greenwood, Mr. J. G. Barford, Mr. John Fielding, and Mr. W. Harrison.

Institution Students' Visit to Germany.—A number of student members of the Institution of Electrical Engineers will set out on Friday, July 9th, for a tour in Germany. On Monday, July 12th, the machine and cable works of the Allgemeine Elektricitäts-Ges., will be visited; on Tuesday, the steam turbine works of the same company and the Technische Hochschule at Charlottenburg; on Wednesday the works of Messrs. Siemens-Schuckert and of Messrs. Dr. Cassirer & Co.; and on Thursday the Reichanstalt and the works of Messrs. Bergmann & Co. The party travels to Cologne on Friday, and will visit some works there on the Saturday, returning to London that night. The cost of a ticket for the tour, including travelling expenses and hotel accommodation for the whole week, is £8 15s., and the tickets are available for 25 days. Students desiring to join the party should write to E. W. Moss, Hon. Sec., 20 Huddleston Road, Tufnell Park, London, N., at once.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published June 24th, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

12,393/08. **Indication of Broken Filaments in Series Running.** W. DIERMAN. Each of the metal filament lamps running in series is provided with a shunt circuit containing a conductor with a negative coefficient, such as a carbon filament. With the main filaments intact, a very small current will pass through the carbon filaments, but should one main filament fail, its carbon filament shunt will have the full pressure across it. A current will pass and its resistance will decrease, so that sufficient current will pass to cause it to glow and indicate the broken lamp. If it is required that the carbon filament shall pass the normal running current of the metal filaments, it is necessary to insert an electromagnetic switch to cut the carbon filament out of circuit when the metal filament passes current. In an alternative arrangement, the electromagnet is shunted across the metal filament, and short-circuits a portion of the carbon filament when the metal filament fails, so that normal current is passed. Four claims, five figures.

16,597/08. **Portable Electromagnet.** W. A. TRIER. An electromagnet is fitted at the end of a rod having a handle and switch, and is intended for picking up screws, nuts, and washers which have fallen into inaccessible places, such as the gear cases of motor-cars. For use on lighting circuits from lamp sockets, a resistance is concealed in the handle. Two claims, two figures.

18,575/08. **Driving of Reversible Rolling Mills.** SIEMENS BROS. DYNAMO WORKS, LTD., C. A. ABLETT, and H. CROWE. The main motor is separately excited, and supplied from a variable voltage generator coupled with a flywheel to a steam turbine. The turbine, which may be of the high, mixed, or low pressure type, is run at a speed about 25 per cent. lower than that corresponding to the most economical steam consumption, this reduction facilitating the construction of the flywheel and generator without seriously reducing the efficiency. By-pass valves for short-circuiting one or more stages of blades, or for admitting the steam to different parts, so that the turbine can deal with sudden overloads, are provided. The turbine speed must be arranged to drop with the load automatically by means of a suitable governor, so that the flywheel can give up some of its energy. Four claims.

18,621/08. **Ignition of Large Gas Engines.** H. N. BICKERTON, P. W. ROBSON, and NATIONAL GAS ENGINE CO., LTD. To obtain more certain ignition, double ignition is provided by means of two separate low-tension magnetos and sparking plugs operated by one gear. Advancement or retardation of the spark is effected at both plugs by a single mechanism, and the plugs, which are fixed at diametrically opposite points in the combustion chamber, can be withdrawn without disturbing the mechanism. Five claims, four figures.

18,856/08. **Tramway Check Rails.** MOUNTAIN & GIBSON, LTD., and P. J. PRINGLE. This is a method of renewing the worn part of check rails, and consists in chipping or grinding the worn surface flat and then fixing a manganese steel strip of angular or V-shaped cross section, shaped so as to be reversible, on to the flat top and against the side. Methods of fixing these strips are described. Three claims, three figures.

25,044/08. **Metal Filaments.** DR. H. KUZEL. When metal filaments are so held by supports that they are compelled to occupy a certain position, it is sometimes found that the tension in the different legs of the filaments varies considerably, often resulting in the breaking of the filament. According to this invention, the filaments are given a square- or polygon-shaped loop with angular corners by hanging a weight from two or more points on the filament during the sintering process. When filaments of this shape are supported loosely at two or more points along the limbs, and not at any portion of the loop, it has been found that unequal tension is avoided. One claim, three figures.

580/09. **Resistance Coils.** SIEMENS-SCHUCKERTWERKE GES. According to this invention, fine wire resistance coils used as series resistances, and liable to heat up considerably, are protected against the breakage of the wires consequent upon the unequal expansion of the inner and outer coils, by inserting silk threads within the insulating covering in a longitudinal direction. These threads must have an elongation under tension smaller than that of the conductor, and must have a higher breaking strength. The threads are said to take up the stresses due to unequal heating, and to permit of more rapid winding of the coils. One claim.

9,265/09. **Joints of Metal Filaments.** BERGMANN-ELEKTRICITÄTS-WERKE AKT.-GES. The cement globules fixing the filaments to the leading-in wires are reduced in a chamber filled with illuminating gas or hydrogen. A pipe admits air or oxygen into this chamber, and the mixture is ignited at the orifice of this pipe. The cement on the joints is reduced in the flame obtained. One claim.

Opposition to Grant of Patents

4,956/08 and 5,040/08. **Manufacture of Metal Filaments.** F. J. PLANCHON. In spite of opposition, the grant of patents on these applications has been allowed. The specifications describe processes for the preparation of plastic tungsten compounds for squirting into filaments, and were abstracted in ELECTRICAL ENGINEERING, January 14th, 1909, page 51, and April 8th, 1909, page 338, respectively.

9,363/08. **Heat Accumulator.** C. NOTBOHM and O. ESTNER. Opposition has been entered to the grant of this patent, which relates to an accumulator in which the intermittent supply of exhaust steam passes through several chambers in succession. Each chamber has an injector-like nozzle, through which cold water is drawn up by suction and mixed with the steam. The low pressure steam generated in the accumulator is passed through a water separator to the low-pressure engine.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad. Summaries of some of the more important of these patents will appear in our next issue.

Arc Lamps: TIMAR and VON DREDGER [Lamps] 12,656/08.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: PARTRIDGE and DAWSON [Supporting and insulating overhead conductors] 5,781/08.

Dynamos, Motors, and Transformers: DOINIKOFF [A.C. commutator machines] 4,852/08; STERN [Speed regulation of induction motors] 12,326/08; MAVOR and MAVOR & COULSON, LTD. [Control of motors] 12,498/08; PIFER and AHLM [Machines] 13,743/08; SIEMENS BROS. DYNAMO WORKS, and KOETTGEN [Ship propulsion] 21,152/08; AKT.-GES. BROWN, BOVERI ET CIE. [Speed regulation of ring spinning frames] 22,349/08; SIEMENS BROS. DYNAMO WORKS, and KLOSS [Cooling of windings] 1,679/09; ALLGEMEINE ELEKTRICITÄTS-GES. [Control of motors] 5,318/09; SIEMENS BROS. DYNAMO WORKS, and O'HAGAN (Partly *Siemens - Schuckertwerke - Ges.*) [Cooling of commutators] 10,067/09.

Electric Ignition: NORMAN and READER [Automatic ignition of electric and other lamps] 17,540/08.

Electrometallurgy and Electrochemistry: CÔTE and PIERRON [Electric furnace] 18,653/08.

Incandescent Lamps: SOC. FRANÇAISE D'INCANDESCENCE PAR LE GAZ (SYSTEM AUER) [Metal filaments] 12,720/08; and [Supports for filaments] 11,149/09.

Switchgear, Fuses, and Fittings: MURRAY [Cut-out] 4,228/09.

Telephony and Telegraphy: SHARMAN [Wireless telephony and telegraphy] 12,140/08; DEARLOVE [Telegraphy] 13,191/08; AITKEN [Telephone instruments] 19,457/08.

Traction: FORSTER [Signalling] 12,518/08; MOUNTAIN & GIBSON, LTD., and HEAD [Foot-pedal sanding gear] 14,222/08; ALBERT THODE & Co. [Overhead section insulators] 14,306/08; WEST [Current collector] 14,695/08; ROGERS & BRECKNELL, MUNRO, and ROGERS [Automatic signalling] 319/09; SCHRODER [Welding of rail joints] 5,916/09.

Miscellaneous: WILDE and PETRIE [Control of lifts and hoists] 12,006/08; STECKEL [Electromagnetic clutches] 28,130/08; POLKEY [Lighting of motor-cars] 4,117/09; SHARMAN [Induction coils] 6,962/09.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

MONNIER [Distributing box for multiple core cables] 13,129/09; ALLGEMEINE ELEKTRICITÄTS-GES. [Brush holders] 13,231/09.

Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

Arc Lamps: W. FAIRBURN-HART (*General Electric Co., U.S.A.*) [Starting of mercury vapour lamp] 5,545/03.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: BRITISH URALITE CO., and R. J. FRISWELL [Fire-proof insulating material] 6,016/02.

Electric Ignition: W. G. WILSON and WILSON & PILCHER [Rotating contact maker] 5,587/02.

Electrometallurgy and Electrochemistry: P. LA COUR and J. J. RINK [Cell for electrolysis of alkaline salts] 5,718/02.

Switchgear, Fuses, and Fittings: OTIS ELEVATOR CO. (*Otis Elevator Co., U.S.A.*) [Switch with rubbing contacts] 6,122/02; C. M. DORMAN and R. A. SMITH [Insulation of inside of switch and fuse cases] 5,861/04; F. TYERS [Cable clip or fastener] 6,035/04.

Telephony and Telegraphy: C. ADAMS-RANDALL [Microphone telephone transmitter] 4,527/00.

Traction: E. A. CAROLAN (*General Electric Co., U.S.A.*) [Pneumatic multiple-unit control] 5,286/03.

Miscellaneous: H. C. WALKER and C. W. HILDRED [Automatic door locks for lifts] 5,173/96.

"Electrical Engineering," although the Cheapest Electrical Paper (Price **1d.** weekly), contains the Most Useful and Practical Articles, the Best Illustrations, and the Latest News. It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.

SUMMARY

THE new 3,000-kw. three-phase turbo-alternator at the Pinkston power station of the Glasgow tramways comprises a Richardson, Westgarth steam turbine of the Parsons type, and a Brown, Boveri two-pole alternator generating at 6,600 volts. The speed of the set is 1,500 r.p.m. Interesting features of the turbine are the special means for fixing the shaft end in the drum at the high-pressure end of the rotor, and the automatic steam-operated bye-pass arrangement. We give drawings to illustrate these and the emergency cut-out gear which closes the stop valve when the speed exceeds a predetermined value. The most interesting features of the alternator are the careful arrangements for thorough ventilation of all parts of the machine, and the method of supporting the end connections of the stator windings. The rotor is built up of annular steel plates, and gun-metal end covers are provided to hold the end windings rigid against the centrifugal forces. Tests made on the set recently showed a steam consumption on full load of 14·66 lbs. per kw.-hour, at 146 lbs. steam pressure, 93·3 per cent. vacuum, and a superheat to 575° F. We also give some details of the condensing plant and of the B.T.-H. motor-operated switchgear used in conjunction with this set. (Page 625.)

A NEW continuous-current machine which has a large number of useful applications, including the reduction of high pressures for low-voltage metal filament lamps, the supply of constant current for low-voltage arc-lamp circuits, and the control of motors on accumulator vehicles and railway cars, has been put on the market by Messrs. Crompton & Co., Ltd. The machine has a ring-wound armature, a divided field system, and a single commutator. There are two short-circuited auxiliary brushes besides the main brushes, and the low-pressure circuit is connected between the auxiliary brushes and one main brush. By the division of the field system into motor and generator portions, and the use of special field windings, the effects of armature reaction are so kept under control that sparking and internal circulating currents are entirely prevented, and almost any desired characteristic is obtained. A demonstration of the behaviour of the machine was given at Messrs. Crompton & Co.'s works at Chelmsford on Friday. (Page 629.)

AN electric heater, in which the radiating bodies consist of quartz tubes containing nickel-wire resistance spirals is described on page 631.

Digitized by Google

A NEW reflector lamp, comprising a low-voltage tungsten lamp enclosed in a flattened globe silvered on one side, will shortly be on the market. Special nickelled flexible conduit for use with these lamps in shop windows and show-cases has also been designed. (Page 631.)

A LETTER in our correspondence columns, from Mr. H. W. Clothier, which was received just too late for insertion in our last issue, takes up some points in connection with a recent criticism of Mr. Nelson's Paper on "Electricity in Coal Mines," especially as regards explosion-proof motor starters and balanced protective gear. A prominent firm also calls attention to some new sizes of metal filament lamp which have been put on the market since the writing of Mr. Hoadley's Paper read before the Municipal Electrical Association. (Page 632.)

THE arbitrator's award has been issued in connection with the acquisition by the London County Council of the Millbank Street power station for the Westminster Electric Supply Corporation. The Council has provided a new site for the company in Horseferry Road, and now has to pay a sum of £181,371 in respect of a new power station, in addition to providing a subway in which pipes for drawing condensing water from the river will be laid. (Page 633.)

WE give an illustrated description of the new Stearn 200-volt 16-c.p. metal filament lamp, which is being introduced, and forms the smallest high-voltage metal filament lamp now obtainable. (Page 633.)

A NUMBER of new Weston instruments of the soft-iron type for use on both alternating- and continuous-current circuits have been placed on the market. The new patterns include both portable and switchboard instruments. (Page 634.)

THE Willesden Urban District Council have entered into a new agreement with the North Metropolitan Electric Power Supply Co. for a supply of electrical energy in bulk from February, 1911, to 1918. (Page 634.)

THE adjourned Local Government Board inquiry into an application by the West Ham Corporation for sanction to borrow £51,600 was held on Monday and Tuesday this week. As on previous occasions the Corporation refused to give any details of the contracts under which electricity is supplied at 0·37d. per unit, and a considerable discussion took place as to the method preparing a scale of charges for large power consumers. Mr. A. H. Seabrook argued that such consumers should only be debited with the capital charges upon the plant installed for this purpose, whereas Mr. Stuart Russell, of the Silvertown Co., and Mr. W. H. Patchell, argued that the capital charges upon the whole of the capital expenditure should be taken into account in respect of every customer. Complaint was made that public lighting has been charged at too high a figure, and that the undertaking had paid practically nothing in respect of rates. Figures were put in showing that the result of last year's trading was a loss of £12,000 instead of a profit of £3,800. On Tuesday the case for the National Electrical Contractors' Association, in opposition, was taken, and Mr. Morten, K.C., summed up on behalf of the Corporation. Several ratepayers asked the Inspector to recommend that a special Local Government Board auditor should be appointed to go into the accounts. (Page 635.)

THE new power station of the Dundee Corporation is now in operation.—The Middleton Electricity Committee have been summoned for permitting the emission of black smoke from their power-house chimney.—There was a profit of £3,451 upon the Oldham Corporation electricity undertaking last year.—A 3,000-h.p. electricity works will shortly be put into operation by the Central Argentine Railway Co.—A bridge is to be constructed across the Metropolitan Railway at King's Cross for carrying tramways.—The Wood Green Council have approved a scheme for taking electricity in bulk from the North Metropolitan Power Co.—A "free" wiring scheme is to be commenced at Durban.—There was a net profit of £3,294 upon the Croydon Corporation Tramways last year. (Page 637.)

THE Port of London Authority require electrical supplies.—Local Government Board inquiries have been held as follows:—Birmingham, £149,350; Southampton, £3,000; Keighley, £12,800; Handsworth, £4,400. Mains are required at York. (Page 638.)

THE capital of the North Metropolitan Electric Power Supply Co. is to be increased by £200,000 preference shares.—The accounts of the Electric Construction Co. for 1908 show a net profit of £3,687 after meeting preference dividend.—The Victoria Falls Power Co.'s accounts for 1908 show a profit of £84,863, including £36,685 from the previous year. (Page 640.)

A PATENT has been taken out by G. W. Partridge and Philip Dawson for a device for indicating the failure of an insulator on high-tension lines or railway overhead construction, and for inserting a supplementary insulator. The device comprises a porcelain tube filled with a fusible insulating compound in which is embedded a fuse wire. Among the other specifications published by the Patent Office on Thursday is one by M. Stern for a stator winding for polyphase motors for giving two different numbers of poles, the whole of the winding being used in each case. A collector for trains or tramcars, comprising a chain of contact pieces which moves in an opposite direction to the motion of the car is described in a specification by A. West. By this arrangement, contact is made with a third rail or contact studs without any wear on the rail or studs and contact shoes, as there is no relative motion between them. Other specifications abstracted relate to the cooling of commutators, the automatic control of motors, and a new form of trolley wire section insulator. Two patents, relating to vulcanising apparatus and signalling lamps respectively, have been granted, in spite of opposition. The grant of a patent to Marconi's Wireless Telegraph Co. for a wave meter is also opposed. Among the patents expiring during the current week is one by M. Moskowitz for a train lighting dynamo, and another by L. Obry for an automatic system of gun-firing. (Page 642.)

MANY interesting statements with regard to the conduct of the municipal electricity supply business were made at the Local Government Board inquiry at West Ham on Monday, but one startling fact has been elicited which may make some Corporation engineers anxious about their electric power supply contracts. Mr. H. Ross Hooper had his attention called to the remarks in Mr. Pearce's recent Presidential address to the I.M.E.A., in which the theory was put forward that, in calculating the capital charges with which a power consumer should be debited in order that the charge per unit should be arrived at, the value per kw. of the new generating plant only should be taken into consideration, and not the average value per kw. of the whole generating plant in the station. Mr. Hooper expressed no opinion as to this, but, from a remark he made, it is clear that he had already made himself acquainted with the contents of Mr. Pearce's address, and that the whole subject of the method of charging for power supply has had his attention. Let us hope that, in the future, he will not take the same antagonistic attitude to this branch of the electricity supply industry as he has taken in the past to electric street lighting. If, in granting electric lighting loans, the Local Government Board tie down local authorities to hard and fast restrictions as to the prices to be charged for power supply, the electrical industry will suffer considerably.

NEW 3,000 KW. SET AT THE GLASGOW TRAMWAY POWER HOUSE

A NEW 3,000 kw. 3-phase turbo-alternator has recently been put into commission in the Pinkston power house of the Glasgow tramway power system.

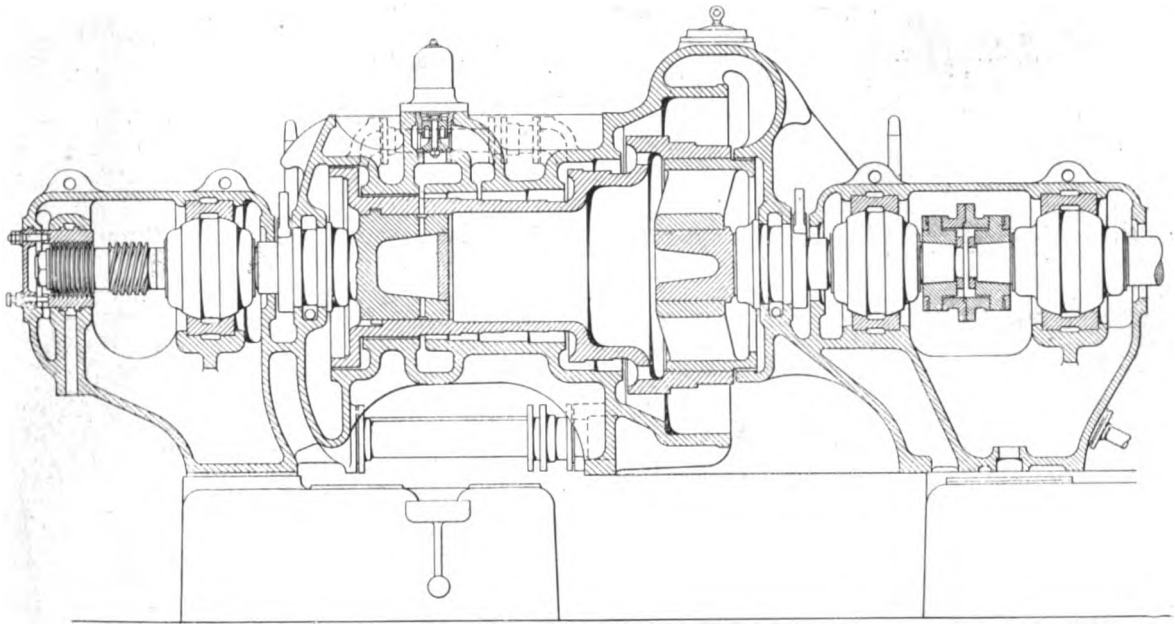

FIG. 1.—LONGITUDINAL SECTION OF RICHARDSON-WESTGARTH TURBINE, SHOWING THE METHOD OF FIXING THE SHAFT END IN THE ROTOR SPINDLE.

The turbine is of the Parsons type, supplied by Messrs. Richardsons, Westgarth & Co., Ltd., of Hartlepool. The specification called for an overload capacity of 25 per cent. continuously, and of 50 per cent. with the high-pressure steam bye-passed into the low-pressure stage. Steam consumptions were specified as follows, assuming steam at 150 lbs. per sq. in., and superheated to 300° C., and circulating water at 20° C.

25 per cent. overload :—14·5 lbs. per kw.-hour at 93·1 per cent. vacuum.
Full load :—14·85 lbs. per kw.-hour at 93·8 per cent. vacuum.
Three-quarter load :—15·75 lbs. per kw.-hour at 94·5 per cent. vacuum.
Half load :—17·75 lbs. per kw.-hour at 95·2 per cent. vacuum.

[With saturated steam the consumption was to be 18·35 lbs. per kw.-hour at 93 per cent. vacuum.]

Fig. 1 is a longitudinal section of Messrs. Richardson-Westgarth's latest pattern of steam turbine, the rotor of which is identical with that of the Glasgow set. Notice may be particularly directed to the special arrangement for fixing the shaft end in the drum at the high pressure end of the rotor. In order to prevent the shaft from working loose in the drum when the turbine is subjected to sudden variations of temperature, an internal chamber is provided at the point where the shaft end is secured to the spindle. To this heating chamber, live steam has at all times access, thereby ensuring that this part heats up simultaneously with the drum. The shaft ends themselves are shrunk on and held fast by bayonet locks. This drawing also shows the automatic bye-pass arrangement which is steam-operated, and opens as soon as the full steam pressure is attained at the first row of blades.

Fig. 2 is a sectional view of Messrs. Richardson Westgarth's emergency cut-out gear, which is employed on the Glasgow turbine. The stop valve is opened by hand through a worm gear, and this compresses a helical spring which is automatically released

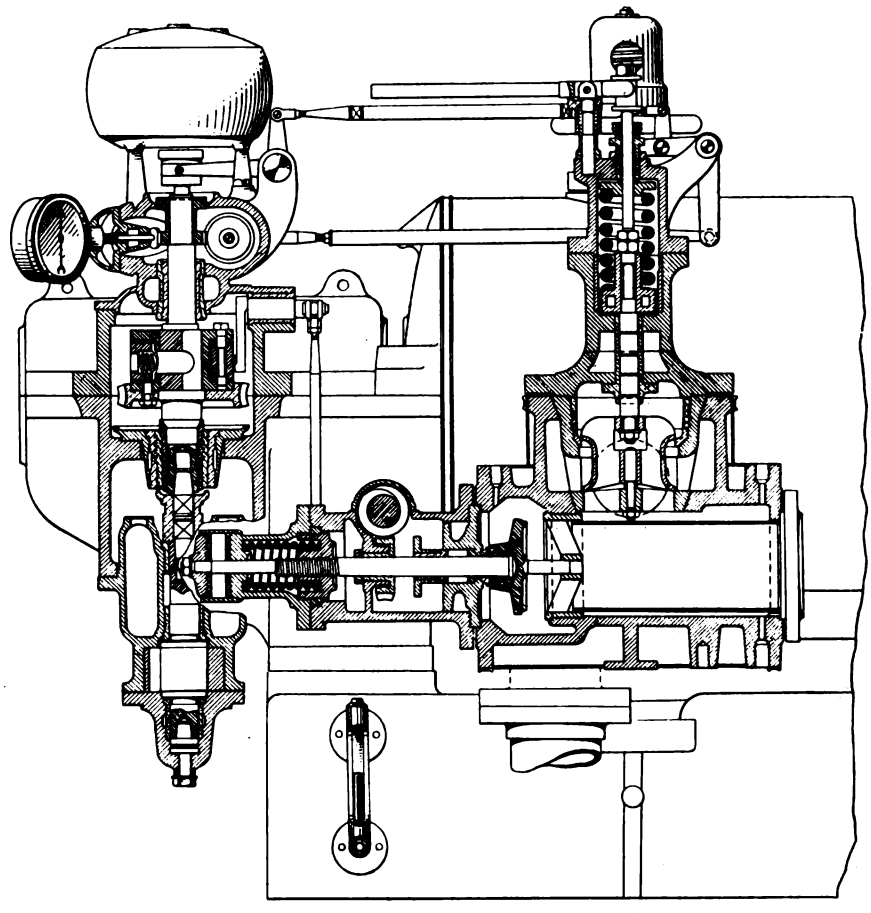

FIG. 2.—SECTION OF EMERGENCY CUT-OUT GEAR.

Digitized by Google

by the governor when the speed exceeds the predetermined value; the complication of a steam relay is thus avoided.

The generator, which is of Messrs. Brown, Boveri & Co.'s latest design, has an output of 3,000 kw. at unity power-factor, at a pressure of 6,600 volts. It runs at 1,500 r.p.m., and being a two-pole machine, generates at a frequency of 25 cycles per second. The overload capacity is 3,750 kw. (namely, 25 per cent. overload) for two hours, 4,200 kw., or over 40 per cent. for half-an-hour; and a considerably larger load for shorter periods.

The maximum temperature rise on full load is 45 deg. Cent., measured by the increase of resistance of the stator or rotor windings, and the efficiencies are as follows:—One-and-a-quarter load, 95·5 per cent.; full load, 95 per cent.; half load, 94 per cent.; and quarter load, 92 per cent. The pressure regulation is within 10 per cent. Excitation is taken from the 100-volt exciter sets previously installed in the station.

The high speed at which the rotor runs, namely, 1,500 r.p.m., while being most favourable to a low steam consumption of the turbine, necessitated most careful design, and we believe that it is the first 3,000 kw. turbo-alternator to be put to work in this country at such a high speed. The orthodox speeds for this size of machine are 1,000 r.p.m. when the frequency is 50 cycles, and 750 r.p.m. when the frequency is 25 cycles, the machines being constructed with six and four poles respectively, instead of only two. The turbines of similar output in the other large station of the Glasgow Corporation (electric lighting and general supply) are four-pole machines, and run at a speed of 750 r.p.m.

Fig. 3 is a general view of the set, from a photograph, taken during erection at Glasgow, and kindly given us by Mr. James Dalrymple, General Manager of the Glasgow Corporation Tramways. This photograph, as is seen, was taken before the erection of the stator, and we therefore add Fig. 4, which is from a photograph of an earlier machine of Messrs. Brown, Boveri & Co.'s make, taken to indicate clearly the general design of the stator, the end shields having been removed. There are over fifty air ducts in the core ensuring a thorough ventilation of the body of the machine. The method of supporting the end connections and the means of holding them rigid against the heavy stresses which might occur on sudden overloads or on short-circuit, are clearly visible in Fig. 4. The arrangement is shown more definitely in the detail drawing, Fig. 5. Both figures show also the wide space which is left between the core and the casing to enable a large volume of air to be drawn through the machine without noise.

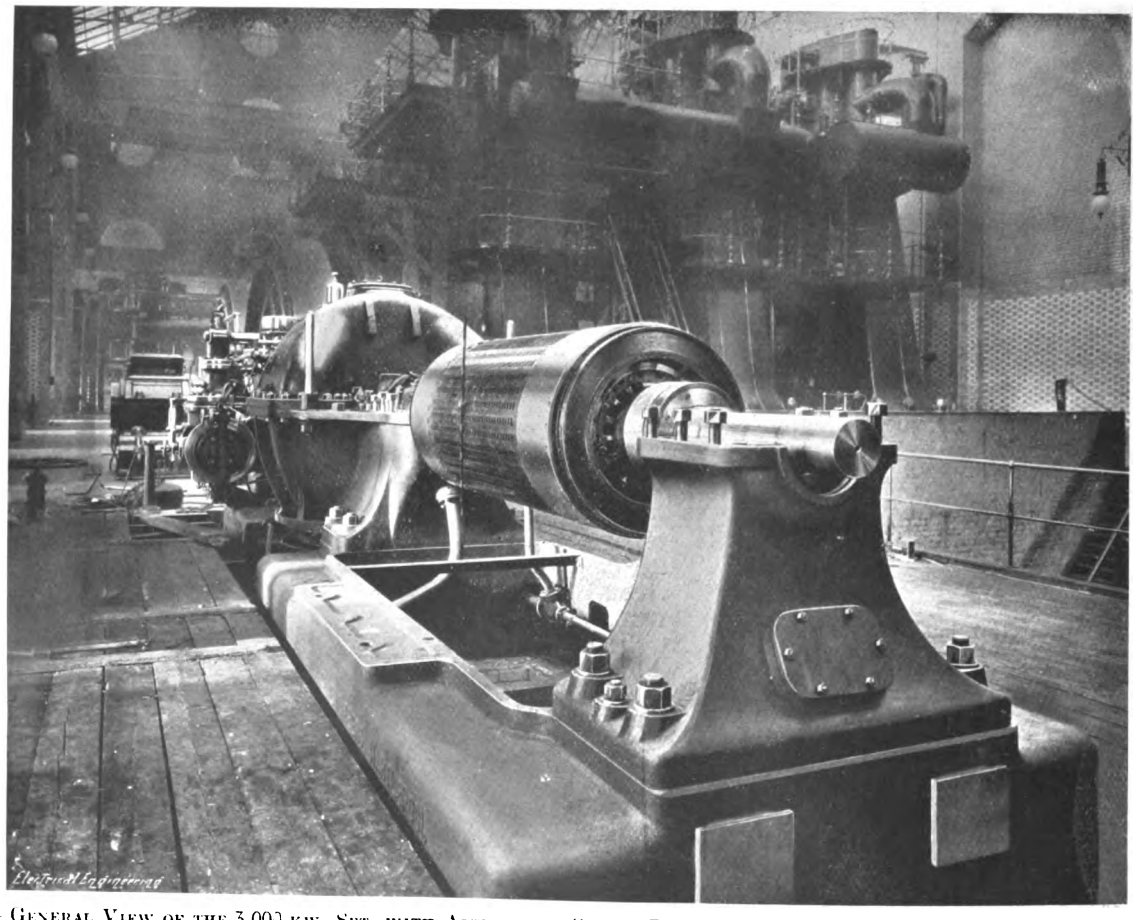

FIG. 3.—GENERAL VIEW OF THE 3,000-KW. SET, WITH ALTERNATOR STATOR REMOVED, FROM A PHOTOGRAPH TAKEN DURING ERECTION.

The wide space between the core and the casing is only one feature of a comprehensive system of ventilation, which is now applied to all the large Brown, Boveri alternators. In this system, cool air is drawn into the machine through two openings in the bed-plate, which enables the air to be taken from the basement. The vanes on the end caps of the rotor, which are clearly visible in the photograph of the Glasgow rotor given in Fig. 6, create a strong draught through every part of the machine. There are, as shown, vanes at each end, and the machine is divided into two separate portions by an annular plate in the stator casing at right-angles to the shaft of the machine, and by a similar construction of the rotor. Each half of the generator has thus a separate air supply and set of vanes. To prevent the upper part of the stator from receiving only air warmed up by a previous passage through the lower part, a portion of the cool air admitted is led direct to the upper part. The opening in the stator casing for this purpose can be seen in Fig. 4,

Digitized by Google

which also shows the baffle plates in the space between the core and the casing to compel the air to pass through the ducts provided in the stator core. Besides this air, which enters the stator direct from the sides, there is another volume of air, blown through the rotor, which finally finds its way out through the ducts in the stator core to the main outlet at the top of the

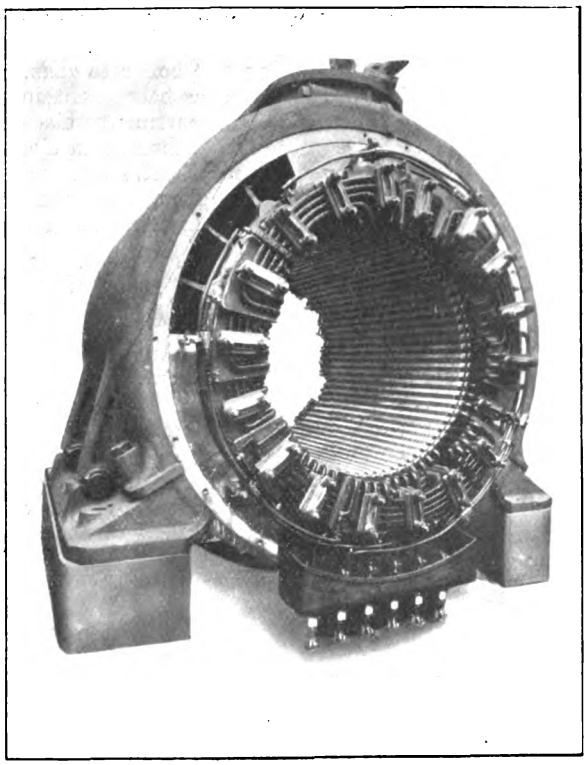

FIG. 4.—VIEW OF A STATOR TO SHOW METHOD OF SUPPORTING END CONNECTIONS.

machine. This air is blown by the vanes through axial passages in the rotor hub; the ends of these are visible in Fig. 3. After passing radially through the ducts between the rotor core plates, the air crosses the gap and enters the stator ducts, through which it escapes to the outside of the core, and finally to the main outlet.

The construction of the rotor is particularly interesting; it is built up of a number of annular steel plates each from $\frac{3}{8}$ in. to $\frac{1}{2}$ in. in thickness, according to the size of the machine. There are 35 of these plates threaded on to the hub, and held together by two thicker plates, one at each end, to which are attached the end covers. The hub is a steel cylinder into which the shafts are shrunk at each end; it is machined inside and outside, and the steel core plates are fixed rigidly to it by heavy keys. The slots for the winding are milled out, and the coils are held in place by metal wedges running the full length of the rotor. Fig. 7 shows the method of disposing of the ends of the coils on the Brown Boveri machines. The end covers, which can be seen in Figs. 3 and 6, prevent the ends of the coils from being displaced under the influence of the centrifugal forces. They are made of gun-metal to

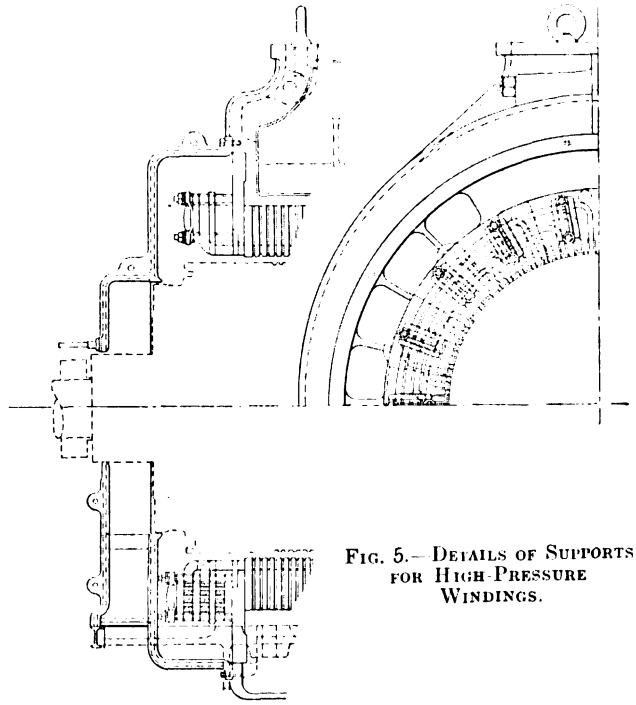

FIG. 5.—DETAILS OF SUPPORTS FOR HIGH-PRESSURE WINDINGS.

prevent magnetic leakage from the rotor field system and, what is more important, to avoid the increase of self-induction of the end-connections of the stator winding which would occur if they were of magnetic material. The slip-rings are of cast steel with copper rubbing surfaces, and the connections from these to the windings are rigidly fixed to the shaft.

The actual tests of the combined set were quoted by Mr. I. V. Robinson, of Messrs. Richardsons, Westgarth and Co., at the recent meeting of the Incorporated Municipal Electrical Association. Working at a pressure of 146 lbs. per sq. in. and a vacuum of 93·3 per cent. ($28\frac{3}{4}$ ins.), and correcting the results for steam superheat to 575 deg. Fahr., the steam consumptions obtained were as follows: On 25 per cent. overload, 14·3 lbs. per kw.-hour; on full load, 14·66 lbs. per kw.-hour; and on $\frac{3}{4}$ load, 15·47 lbs. per kw.-hour.

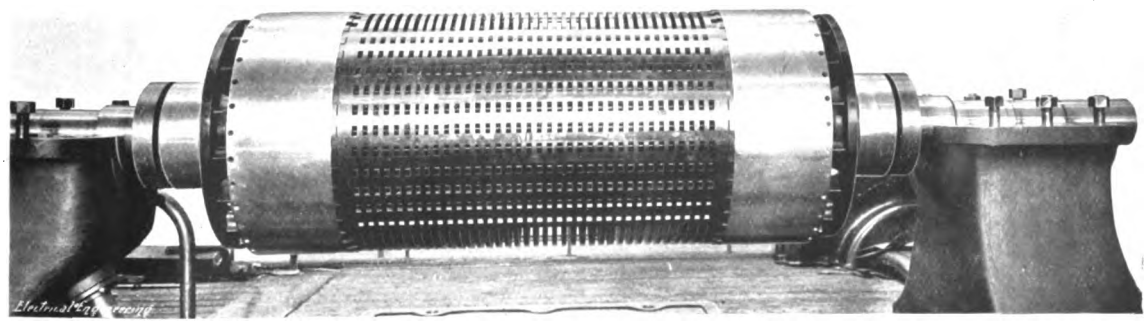

FIG. 6.—ROTOR OF THE 3,000-KW. ALTERNATOR AT THE GLASGOW TRAMWAY POWER-HOUSE.

Digitized by Google

The condensing plant, supplied by the Mirrlees Watson Co., Ltd., of Glasgow, consists of a surface condenser, a set of three-throw electrically-driven air pumps, and an electrically-driven water circulating pump. It is designed to deal with 50,000 lbs. steam per hour, and to give a vacuum within 1·5 in. of the barometer with circulating water at a temperature of 60° F. The condenser has 7,050 sq. ft. of cooling surface. It is designed on the counter-current principle, with the tubes divided into separate nests, and arranged for compartmental drainage. The air pumps have three barrels, each 20 in. diameter by 12 in. stroke. The pumps are directly connected by flanged coupling to a slow-speed motor of the Lancashire Dynamo Co.'s make, running at a speed of 133 r.p.m.

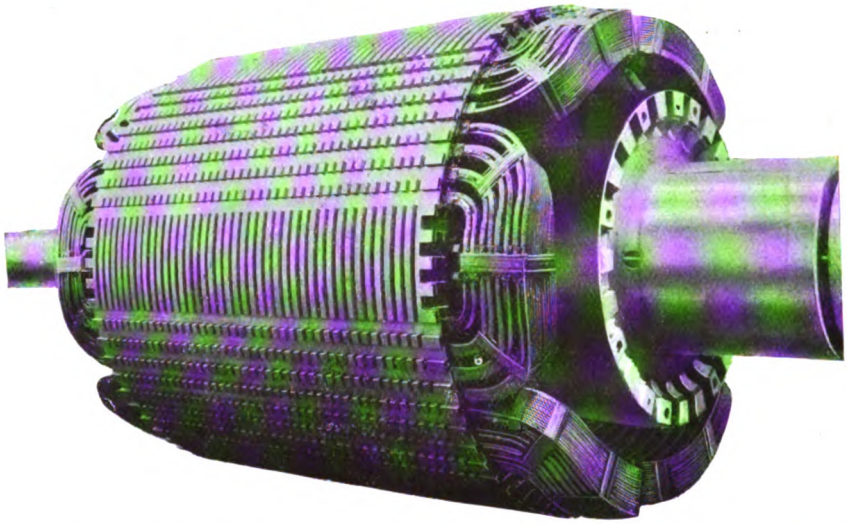

Fig. 7.—Showing the Method of Disposing of the End Coils of the Rotor.

The centrifugal water pump is capable of delivering 5,600 gallons of water per minute against a total head of 18 ft., requiring about 40 b.h.p. for operation.

Steam for the turbines is supplied by six new Babcock & Wilcox boilers, with the latest form of chain-grate stoker and gear. The boilers are rated to evaporate 2,500 lbs. per hour, and generate steam at a pressure of 160 lbs. per sq. in., superheated to 550° F. Two new sets of electrically-driven three-throw boiler feed pumps are duplicate of the four sets of pumps supplied by the Mirrlees Watson Co., with the original reciprocating engines installed at this station. Each of these pumps is capable of delivering 8,000 gallons of water per hour against a pressure of 180 lbs. per sq. in. They are driven through double-reduction gearing from a 27½ b.h.p. motor of the Lancashire Dynamo Co.'s make. They are of very substantial construction, the crank-shaft being supported between each set of cranks.

Fig. 8, which we are able to reproduce by the courtesy of the British Thomson-Houston Co., of Rugby, shows the construction of the latest type of B.T.-H. motor-operated high-tension switch, which is used in connection with this new set. The switch is mounted, together with others, in spacious brick and concrete cells, each of the three phases being contained in a separate compartment absolutely distinct from the others, and closed in by separate doors. The stroke of the switch is 20 inches, and there are two breaks per pole of about 17 inches clear length.

The operation of the switch is extremely rapid, as both the closing and opening strokes are made by the release of powerful springs. The mechanism is so arranged that after the spring has operated the switch, the motor follows up and strains the spring ready for the next operation. The momentum at the end of this stroke is taken up by buffer springs, and is then stored for use for accelerating the succeeding stroke.

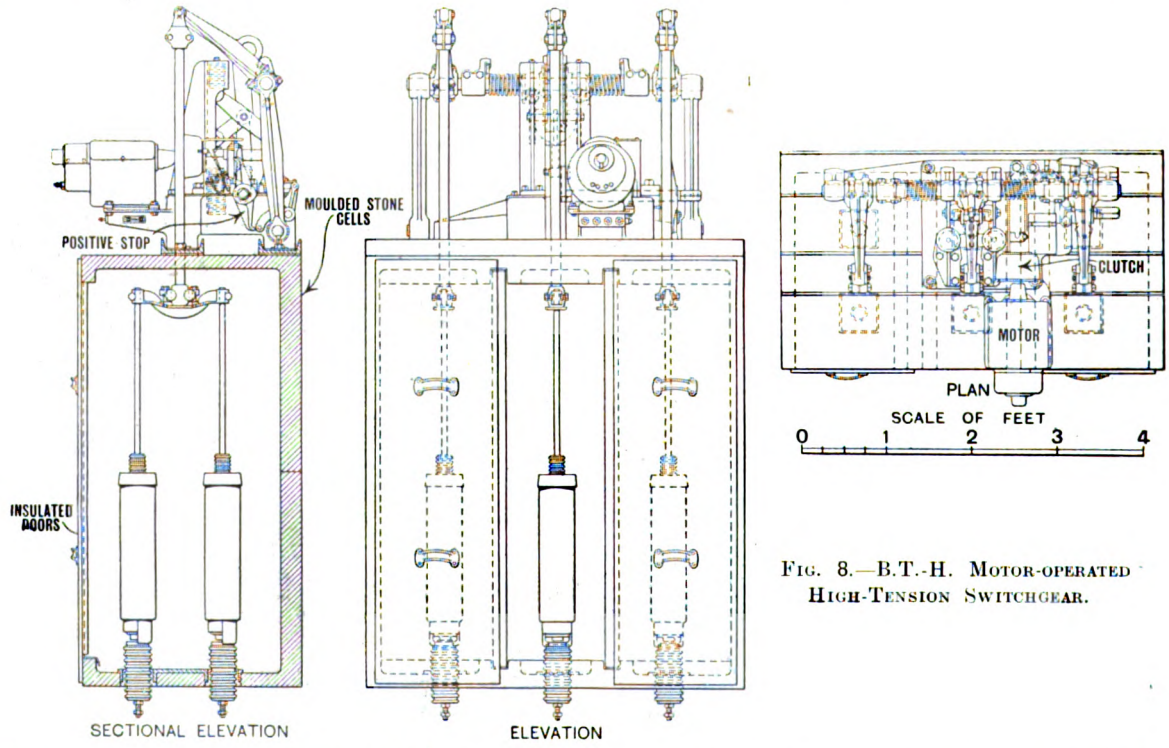

Fig. 8.—B.T.-H. Motor-operated High-Tension Switchgear.

Our thanks are due to Mr. Dalrymple, General Manager of the Glasgow Corporation Tramways, for permission to inspect the new plant, and also to the various contractors who have assisted us with detailed information and drawings.

Electric Railways in Switzerland.—According to the *Financial News*, the length of electric railway lines, which in 1901 was 400 kilometres, amounted in 1908 to 1,019 kilometres, which represented about 18 per cent. of the Swiss railway system. The total amount invested so far in electric railways and tramways is about 104,000,000f. As to the returns, the figures for 1907 vary between 4,713f. per kilometre (Jorat Railway) and 89,842f. per kilometre (Jungfrau Railway). Only a few of the companies are paying a dividend, and this will be so for some years to come, as the profits are devoted to the payment of interest on loans contracted and to the creation of legal reserves.

A CONTINUOUS-CURRENT TRANSFORMER

A DEMONSTRATION of a new machine which has been put on the market by Messrs. Crompton & Co., Ltd., of London and Chelmsford, under the name of the C.M.B. (Crompton, Macfarlane, and Burge) patent auto-converter, was given at their Chelmsford Works on Friday last. This machine is primarily a continuous-current rotary transformer, but it has the important additional feature that the secondary pressure can be automatically regulated so as to render the machine suitable for a variety of special purposes. Many years ago, it was proposed to construct a continuous-current transformer by putting auxiliary brushes at intermediate points between the main brushes, but the present machine is the first in which this idea has been realised in a practical manner.

In its simplest form, the C.M.B. machine consists of a ring-wound armature with a single commutator, and a two-pole field system divided into two parts, as shown in the diagram of Fig. 1. In this diagram *a* is

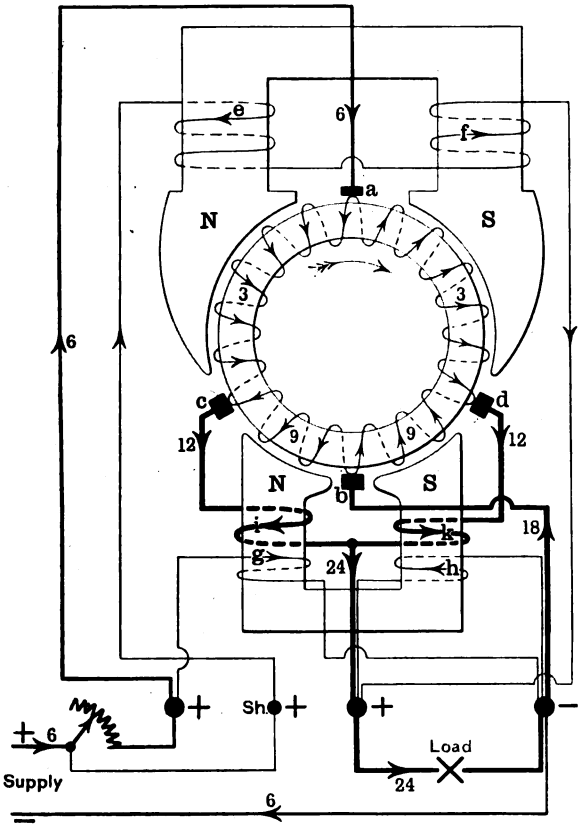

FIG. 1.—DIAGRAM OF CONNECTIONS FOR A C.M.B. AUTO-CONVERTER ARRANGED FOR SUPPLYING CONSTANT CURRENT.

the main positive, and *b* the main negative brush, and these are connected to the supply mains through an ordinary motor-starter. The auxiliary brushes are represented by *c* and *d*, their position on the commutator being determined by the ratio of transformation required. If *a* is the positive brush, and the shunt windings (*e*, *f*) are connected as shown, the armature will rotate in a right-handed direction, and the motoring parts of the armature will be those between the brushes *a* and *c*, and *a* and *d*. The generating portions of the armature are those between the main brush *b* and the auxiliary brushes. In order that the potential of the two auxiliary brushes shall remain the same at all loads, it is essential that the potential curve round the commutator should remain symmetrical. To reduce the distortion of the curve by armature reaction, and the consequent variation in the pressure at the auxiliary brushes, the poles are divided as shown, with the result that there is a very high reluctance to the armature cross-flux. By this division of the poles, the motoring and generating fluxes are entirely separated, and either side of the machine can be compounded so as to give any desired characteristic. The sectional areas of the poles are in proportion to the ratio of transformation. The division of the poles also flattens the potential curve at the points where the auxiliary brushes are placed, and this tends to prevent sparking.

To make the action of the machine quite clear, we have inserted figures which show the relative current strengths in the different parts for an assumed voltage ratio of 4 : 1, neglecting the shunt current and assuming an efficiency of 100 per cent. It will be seen that the machine acts as a true auto-transformer, the current in the generator portion being the difference between the load current and that supplied from the mains to the motor part.

The diagram of Fig. 1 shows the connections for a machine wound to give a drooping characteristic, that is, a characteristic half-way between that of the ordinary shunt-wound and that of a differentially-wound machine. Such a machine will automatically maintain a constant secondary current over a wide range of voltage, and is especially suitable for supplying arc lamps, as the latter can then be run without any steadying resistance. A 5-kw. auto-converter of this design was shown to the representatives of the Press on Friday. The machine was running off a 225-volt supply circuit, taking 16·8 amperes, and was supplying 52 amperes to an arc lamp at 51 volts. Thus, although it was only a 5-kw. machine running at half-load, an efficiency of over 70 per cent. was obtained, which is considerably more than what a motor-generator would give under similar conditions. We saw the machine short-circuited, but this only resulted in a slight increase in speed (some 10 to 15 per cent.). It will be seen from Fig. 1 that the currents from the two auxiliary brushes are first carried through the series windings (*i* and *k*) of the generating poles, which are in opposition to the shunt windings. This has the effect of correcting the inevitable departure from symmetry in the potential curves, as well as giving the required drooping characteristic, as if the potentials of the two auxiliary brushes are not the same, a circulating current will be superposed on the load current. This circulating current will magnetise one pole and demagnetise the other, and thus correct the dissymmetry. The circulating current thus plays an important part in the regulation of the machine, and if properly regulated can be used to effect a special control of the speed and of the general characteristics of the machine.

In Fig. 1, one shunt winding of the generator field (*g*) is connected between one supply main and the auxiliary brushes, while the other (*h*) is connected across the load, this arrangement also tending to neutralise the effects produced by armature reaction. There are, however, several combinations, the most suitable arrangement depending on the purpose for which the machine is to be used.

In the patent specifications, covering this machine, it is stated that it is reversible, as to transform up, the current has only to be supplied to the short-circuited and the negative brushes. Further, it is said that if it is desired to transform from A.C. to D.C., the armature is provided with slip-rings connected to the proper points of the armature, and the machine is run as a synchronous motor. The main shunt is connected between the positive brush and the short-circuited brushes, and the load is connected between the short-circuited brushes and the negative brush. This machine has an advantage over the ordinary rotary

Digitized by Google

converter in that the pressure on the D.C. side can be varied without affecting the power-factor on the A.C. side, as by simultaneously and oppositely altering the fields of generating and mooring sides, the total flux is kept the same and the power-factor unaltered. The divided field construction can be applied to large multipolar machines, and, if necessary, commutating poles can be added.

Fig. 2 illustrates the mechanical construction of the machine. The armature winding is wound on a laminated slotted ring carried on a spider keyed to the shaft. The latter runs in ball bearings which require the minimum of attention and are noiseless. Carbon brushes are provided, and these require no adjustment after having once been set in the correct position.

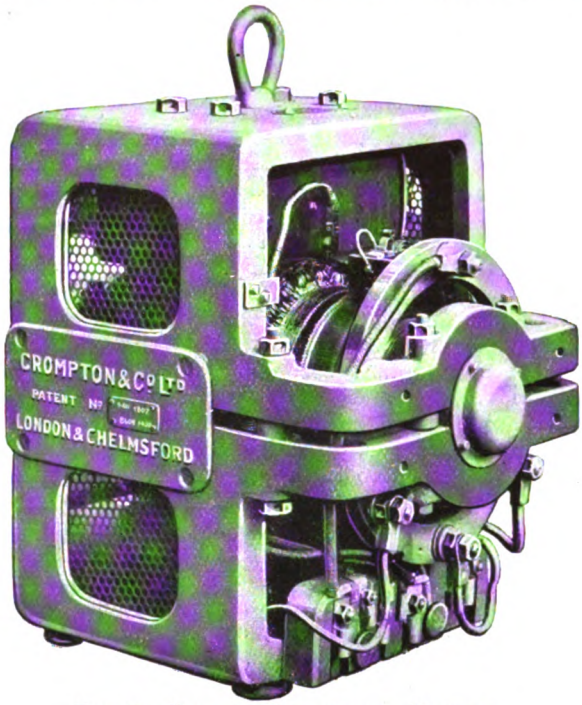

FIG. 2.—GENERAL VIEW OF THE MACHINE.

An important application of this machine is its use as a three-wire balancer, its advantages over the ordinary balancer being higher efficiency, lower cost, and smaller floor space. Another useful application is for the reduction of a high supply voltage to some lower figure better suited to the use of metal filament lamps or for battery charging. The series coils on the generating poles assist the shunt windings in this case so as to give constant pressure with varying load. The machines can be obtained for primary voltages of 550 and under, and with transforming ratios up to 1 to 10. With higher ratios than this, the efficiency is rather low.

It is stated that the efficiency for normal ratios (about 1 : 4) varies from 75 per cent. at full load to 70 per cent. at half load in the case of a 2-kw. machine, to from 91 per cent. at full load to 88 per cent. at half load for a 20-kw. machine. We are also informed that the weight of a transformer of this pattern is about 50 per cent. less than that of a motor-generator of the same capacity.

A system of control for electric vehicles which includes the use of one of these machines, has been developed by Messrs. Crompton & Co. With this system, a wide range of control over the accelerating and running speed of the motors is obtained, and regenerative braking is easily effected by returning power to the battery, the whole of the regulation being done by means of a resistance and switch in the field-circuit of the auto-converter. The latter is in this case provided with special field windings to limit the current taken from the battery and regulate the supply of current to the motors, so that gradual acceleration and braking is ensured. An accumulator omnibus with this system of control has been making experimental runs in London recently, and was used on Friday to convey the Press party to and from the works and Chelmsford station.

The machine can also be applied to railway work to supply a large current at a low pressure at starting, thus raising the overall efficiency of the equipment. Regenerative braking can also be employed. Other applications include colliery winding, the electric driving of continuous running and reversible rolling mills, electrolytic processes, electric welding, the driving of printing machinery, and other power work.

When applied to the driving of electric cars for railway work, or similar cases where a variable speed is required, the driving motors have their fields separately excited from the supply mains, current being supplied to the armatures at a low pressure at starting by means of the auto-converter. As the speed of the driving motor increases, the pressure across the armatures is increased automatically. All series resistances are thus avoided.

Besides the auto-converter, there were several other interesting machines to be seen at Messrs. Crompton & Co.'s works on Friday, among which was a special motor-generator for electric welding. This supplies some 600 amperes at somewhat under 20 volts, the pressure on the primary side being 550 volts. One generator shunt winding is separately excited off the 550-volt mains, and the series winding is in opposition, so that it is quite safe to short-circuit the machine. There is a third shunt connected across the generator brushes.

There were also a couple of motor-generators destined for Admiralty wireless stations on the test-bed. Each consisted of a three-phase induction motor direct-coupled to a 28-pole generator. As the speed of the sets is 1,500 r.p.m., the frequency on the secondary side is 350 cycles per second. These are two of a large order for 90 similar sets. A feature of the induction motors used is that the slip is only 1 per cent. at full load.

Electric Coal Cutters.—The report of Mr. H. Hall, Inspector of Mines for the Liverpool and North Wales District, records the use of 18 electrically-driven coal-cutting machines, as compared with 11 in 1907. The total number of machines, including those worked by compressed air is, according to the *Iron and Coal Trades Review*, however, slightly less than last year, and is now 131.

Conversazione of the Institution of Electrical Engineers.—The annual conversazione of the Institution of Electrical Engineers was held on Wednesday, June 30th, at the Natural History Museum, South Kensington, and a large number of ladies and gentlemen were received by the President, Mr. W. M. Mordey, and his daughter. The gathering was made all the more pleasant by the music provided by the string band of the Royal Engineers and the vocal selections given by the Alexandra Ladies' Quartette, and the brightness of the scene was enhanced by the appearance in uniform of Col. R. E. Crompton, C.B., and officers of the Electrical Engineers (Territorials). Among those present may be mentioned :—Mr. J. Ardron, C.B., Prof. H. E. Armstrong, F.R.S., Prof. H. T. Povey, Prof. H. L. Callender, F.R.S., Prof. H. S. Carhart, Prof. H. Cox, Prof. H. T. Davidge, Mr. W. Duddell, F.R.S., the Right Hon. W. G. Ellison-Macartney, Mr. G. K. B. Elphinstone, Colonel J. A. Ferrier, C.B., R.E., Prof. G. Forbes, F.R.S., Mr. S. G. Gamble, Sir John Gavey, C.B., Mr. F. Gill, Mr. J. Hunter Gray, Mr. R. K. Gray, Mr. Charles Hawksley, Captain the Hon. F. Hemphill, Prof. O. Henrici, F.R.S., Colonel H. C. L. Holden, R.A., F.R.S., Colonel Sir T. H. Holditch, R.E., Mr. W. Judd, Dr. G. Kapp, Mr. J. E. Kingsbury, Mr. G. C. Lloyd, Dr. T. M. Lowry, Mr. C. O. Mailloux, Mr. T. Mather, F.R.S., Major W. A. J. O'Meara, R.E., C.M.G., Sir C. J. Owens, Sir Robert J. Parker, Mr. G. W. Partridge, Prof. J. Perry, F.R.S., Sir William H. Preece, K.C.B., F.R.S., Mr. J. H. Rider, Mr. R. A. Robinson, Brigadier-General R. M. Ruck, R.E., Mr. J. F. C. Snell, Mr. C. E. Spagnoletti, Mr. C. P. Sparks, Mr. J. Swinburne, F.R.S., Prof. S. P. Thompson, F.R.S., Prof. Sir T. E. Thorpe, F.R.S., Prof. W. A. Tilden, F.R.S., Sir C. E. Troup, K.C.B., Prof. W. C. Unwin, F.R.S., Mr. A. J. Walter, K.C., Mr. G. G. Ward, Mr. C. H. Wordingham, and Prof. W. P. Wynne.

NEW ELECTRIC HEATER

THE first example of a series of new patterns of electric heating and cooking apparatus, which are being manufactured under the Bastian patents, has been put on the market by Messrs. Drake and Gorham, Ltd., of 66 Victoria Street, Westminster, S.W., in the form of an electric radiator. This device, which is shown complete in Fig. 1 below, is very light and compact, and is especially adapted for the heating of offices, dressing-rooms, ships' cabins, railway cars, &c. It consists of

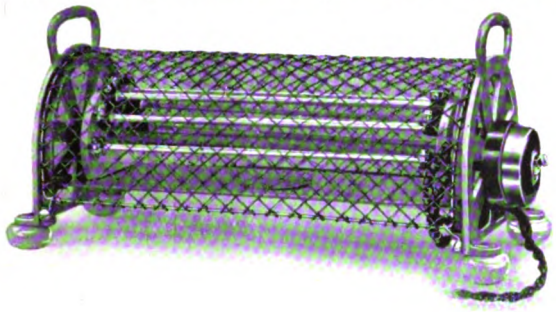

FIG. 1.—QUARTZ HEATER WITH WIRE COVER.

six horizontal quartz tubes or glowers, each of which contains a spiral of pure nickel wire. The resistance of these spirals is such that the glowers and the spirals within them are brought to a bright red heat within fifteen seconds of the current being switched on. The use of the quartz tubes renders a high temperature possible, and considerably increases the radiating power of the device.

Fig. 2 shows one of the quartz tubes, each of which is about

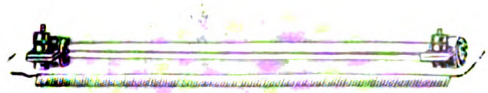

FIG. 2.—ONE OF THE QUARTZ TUBES AND A RESISTANCE SPIRAL.

12 in. long by $\frac{3}{16}$ in. diameter. They are held in metal clips, the tightening screws of which have an additional nut and act as terminals for the ends of the resistance spirals. The metal clips slip into spring contact pieces attached to the porcelain end plates, as shown. The resistance spirals have a life of from 1,000 to 2,000 hours, as the oxidation is very slight, but when they do burn out they are easily replaced, and cost only 6d. each. The quartz tubes last indefinitely, as they can be

FIG. 3.—QUARTZ HEATER WITH COVER REMOVED.

damaged only by mechanical shock. They are not, however, very costly. The illustration of Fig. 3 shows the heater with the protecting cover removed. It will be noticed that there is an aluminium reflector below the quartz tubes to concentrate the heat rays in an upward direction. This figure also indicates the construction of the heater, the metal rod connecting the two cast-iron end pieces being clearly visible.

These radiators are usually connected so as to consume 750 watts, or three-quarters of a unit per hour, but can be also obtained to consume 1,000 watts. The total length of the heater is only 14 inches, and so it can easily be fixed below a desk or on a wall or in any other suitable position. Ovens, grills, and water-boilers, as well as other cooking apparatus constructed on the same principle as this radiator will shortly be constructed.

NEW SHOP-LIGHTING FITTINGS

A NEW pattern of reflector lamp, especially designed for the lighting of shop windows and show cases, by Mr. S. Horvath, of 51 Standen Road, Southfields, S.W., is being manufactured by him at his factory at the above address, and will shortly be put on the market, together with a special fitting for mounting the lamps, by Messrs. Krupka & Jacoby, of 11 Queen Victoria Street, London, E.C., who are the sole selling agents for the United Kingdom.

The lamp itself consists of a small tubular bulb, containing two or three tungsten filaments, and provided with a special cap, the construction of which can be seen in Fig. 1. Three thumb screws are provided on the extension to the cap, and these grip the outer bulb. Holes are cut in the metal as shown, for ventilation. The outer globe is flattened, and one side is silvered, and the coating protected by a thick deposit of copper. As the lamp is brought so close to the reflector, a very complete reflection in a direction vertical to the plane of the reflector is obtained, as is shown in Fig. 2, which is a

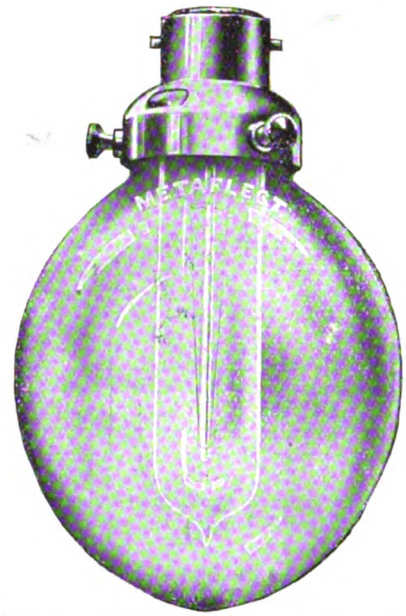

FIG. 1.—"METAFLECT" LAMP COMPLETE.

curve of horizontal candle-power, taken at the National Physical Laboratory with the reflector. The lamp tested was a 25-volt lamp with two filaments, rated at 12 candle-power. The N.P.L. report states that the curvature of the reflector is such that a large part of the light is concentrated in an approximately parallel beam, increasing the intensity of the light in the direction of the axis of the reflector about five times. Thus the horizontal candle-power without the reflector was 18·8 c.p., and with the reflector at the centre of the beam it was 97 c.p. The curve, Fig. 2, was taken after the lamp had been turned round so that the horizontal candle-power without the reflector was 15 c.p., and the maximum candle-power with the reflector was only a little over 60 c.p. According to the report, the efficiency of the lamp is exactly one watt per horizontal candle-power without the reflector.

The lamps are made for 25 and 50 volts, the latter size having three filaments. For shop lighting, eight of these lamps are mounted in series or parallel, according to the supply pressure, eight inches apart, on a nickel-plated steel conduit tube, and, two or more of these tubes are connected together by flexible steel tubing, and run up the sides or along the top or bottom of the window frame. Special holders and clips are provided for attaching the lamps to the tubes, and they are fixed so that the tubular lamp itself is parallel to the tube. The whole arrangement is remarkably simple to fit up, and the reflecting outer globe can be moved round so that the light is concentrated in any desired direction.

Mr. Horvath kindly showed our representative over his factory on Monday, and we were able to see the lamp in various stages of manufacture. The tungsten filaments themselves are obtained from a well-known firm, and are made in England, but are mounted and fitted in the bulbs at Mr. Horvath's factory. They are fixed to the nickel leading-in wires with a tungsten cement (Hyde's patent), which is reduced in a special apparatus. This comprises a glass cylinder closed at the top. This is supplied from the top with a constant flow of hydrogen

Digitized by Google

which displaces all the air. A carbon electrode is inserted through an aperture in one side, and the filament frame is inserted from below. The secondary terminals of a 1,000 volt transformer are connected to the carbon electrode and the frame,

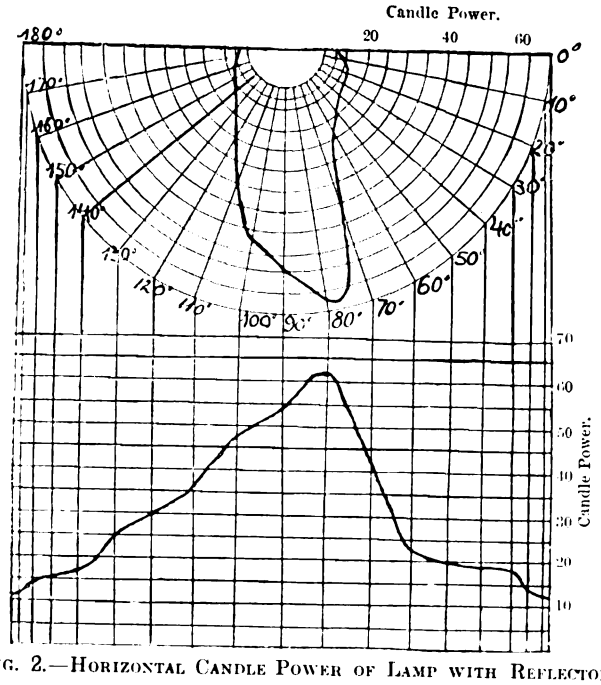

FIG. 2.—HORIZONTAL CANDLE POWER OF LAMP WITH REFLECTOR.

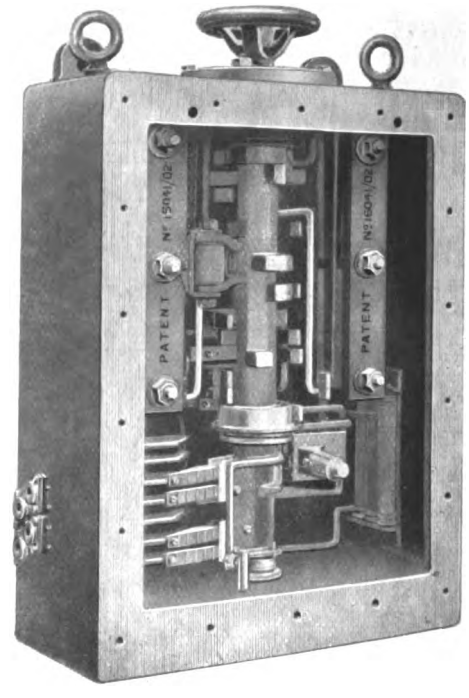
and the arc produced not only reduces the cement, but melts the end of the nickel support, and effects a durable carbon-free joint. Forty filament frames can be treated in one hour with this apparatus. The filaments are supported at the top of the glass pedestal by flat platinum-iridium springs, which keep the loops in tension. Among the other interesting pieces of apparatus used is a new pattern of horizontal sealing-in machine, with which 500 lamps can be sealed per day. For exhausting, the "Gaede" type of rotary mercury pump is used, in which a drum, divided into chambers, rotates in an iron vessel half-filled with mercury, and sucks the air and the gases expelled from the filaments, out of the lamp bulbs.

CORRESPONDENCE

ELECTRICITY IN COAL MINES.



To the Editor of ELECTRICAL ENGINEERING.

DEAR SIR,—Judging by his letter in your last issue, we are afraid that your correspondent "A. G. C." has not seen the descriptions which have been published of a type of explosion-proof switch case which is made by us for use in mines; otherwise we think that he would have taken a different view of the subject. We can well imagine that switch-cases which are made too flimsy are liable to burst in the event of an internal explosion, but there is no mechanical reason why the cases should not be designed and cast strong enough to withstand the maximum pressure which it is possible to obtain by the ignition of an explosive mixture of methane and air in any proportion.

Mr. Simon in his Paper before the Institution of Electrical Engineers, read in Glasgow on March 29th, 1909, in recording the results of some authentic experiments, says, in connection with vessels containing single compartments:—"The maximum pressure developed in a vessel of moderate capacity by an explosion of accumulated firedamp is about 6·5 atmospheres." Our own experience tends to show that there is no difficulty in designing switch cases with a factor of safety sufficient to ensure against rupture due to an internal explosion of the nature in question, and we beg to enclose an illustration as an example of such a box which contains a drum type motor starter. The wide metal to metal joints on this type of box may be depended upon to prevent the possibility of an emission of flame, and so, not only will it withstand an internal explosion, but it will do so without risk of igniting gas or coal dust which may be in the surrounding atmosphere.

There is another point in "A. G. C.'s" letter which concerns our designs, and upon which we think some further explanation may be to the point. As we are reminded by "A. G. C.," the "Merz-Price" balance system of protection is by no means novel. This system, as known at present, however, involves the use of pilot wires. The pilot wires are absolutely necessary for the protection of a ring main or duplicate feeders, where the object is to isolate any faulty section of the network without interfering with the continuity of supply to the other sections. Now if Mr. Nelson's Paper is read intelligently, it will be seen that, besides describing the protective system introducing the use of pilot wires, he also clearly describes a simpler system of protection which does not require the use of pilot wires. It is based upon the fact that on a 3-phase cable without leakage the algebraical sum of the currents in the three conductors at any instant of time must be zero, but immediately a leakage to earth occurs this balance is upset. By this principle we are enabled to use a simple arrangement of trip coils which will automatically open an oil break switch instantaneously, when a leakage to earth of sufficient amplitude to be dangerous occurs.

We think it is not generally appreciated that the balance method of protection can be used without pilot wires, and, moreover, with trip coils which, if anything, are less intricate than those required for ordinary overload protection. The

most useful features are that it is a system by which instantaneous isolation can be obtained in the event of a fault to earth, and at the same time an inverse time limit protection is obtained for dealing with ordinary overloads or faults between conductors, which are not serious from an explosion point of view until they develop into faults to earth, when they would be instantaneously isolated. As considered in comparison with the system using pilot wires, it must be understood that, as a discriminating device, it has a narrower range of usefulness in that it only discriminates between a leakage to earth and ordinary overloads or faults between phases. For example, where two cables are run in parallel, and it is necessary to isolate one when a fault occurs without interfering with the other, we must work with a balance between the ends of each cable, and this involves the use of a pilot wire, but if it is not a matter of importance to maintain an absolute continuity of supply, and of no great inconvenience to have both these cables cut out for a fault on one of them, or again if only one cable is used, as in the common case of a cable running down a shaft, then the balance system without a pilot wire can be used to advantage.

We are afraid this is a lengthy subject to make clear in a letter of this description, but if any of your readers wish to have further information, we would be prepared at any time to discuss fully with them the subject, with special reference to their particular conditions.

It must be a source of satisfaction to Mr. Nelson that his Paper has given so much food for reflection, as is evidenced by criticisms such as those now made by "A. G. C.," and there is no doubt that good may come of this, even though the comments are put in such a way as to prove that the critics have not clearly understood the original subject-matter.

We hope you will consider that the importance of this subject warrants the above explanation in your columns, appreciating as we do the necessity of giving serious attention to any scheme which shows promise of improving conditions which concern the safe application of electricity in mines.

Yours faithfully,
For A. Reyrolle & Co., Ltd.,
H. W. CLOTHIER.

Hebburn-on-Tyne.

[Messrs. Reyrolle's letter was written on Wednesday last week, and they had therefore not at that time seen Mr. Field's article on a protective device for three-phase feeders published in our last issue.—ED. E. E.]

METAL FILAMENT LAMPS.

To the Editor of ELECTRICAL ENGINEERING.

DEAR SIR,—We have studied with great interest the article on the influence of metallic filament lamps on the electrical industry and on street lighting, read by Mr. E. E. Hoadley, the Corporation Electrical Engineer, Maidstone, at Manchester last week.

We would, however, like to point out that a high voltage Aegma metallic filament lamp is obtainable, giving 25 c.p., and consuming 30 watts only, at 4s. 3d. This is a considerable advancement on the 50 c.p., presumably 60 watt, lamp mentioned by him; in fact, we are of the opinion that it is as small a wattage lamp as is required. The public, once having been educated up to the higher standard of light, are now no longer satisfied with a 16 c.p. lamp, as formerly.

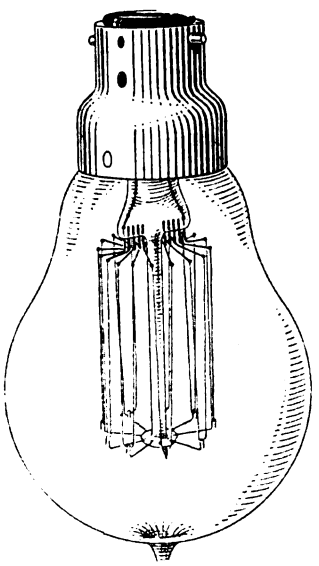
Yours faithfully,
The Electrical Co., Ltd. (Lamp Dept.),
W. H. WILLIAMS.

121-125 Charing Cross Road.
June 30th, 1909.

VALUATION OF A GENERATING STATION

THE arbitrator's award was given last week in connection with the valuation of the Millbank Street power station of the Westminster Electric Supply Corporation, Ltd. The site of this station, which, it may be mentioned, is the oldest station of the Westminster Co., is to be acquired by the London County Council in connection with the extension of the Thames Embankment and the improvements to be made in Westminster at this spot. The Act of Parliament which authorised the L.C.C. to acquire this and other sites, directed that in this case the Council should provide an equivalent site for the company's station, and that they should pay the company the cost of erecting a new generating station upon the new site equivalent to that of the existing station at the time of the removal, and also make good to them the cost of any alteration in the mains that might be necessary. Also, if the facilities for condensing and for the cartage of coal at the new station were not equal to those at the old one, the Council were to pay to the company a lump sum by way of compensation for the loss of these facilities. During the erection of the new station the old one will continue to run, and the company is only to relinquish the old station when the new one is absolutely completed. The L.C.C. will then enter into possession of the old station, including the old plant. The Council have provided a site larger than the one at Millbank Street, and in respect of the extra amount of land, the company will make a payment to the Council. The new site is in Horseferry Road, some 300 yards away from the river.

In the arbitration which has just been concluded to decide the sum to be paid to the company, they made the following claim:—Buildings, £73,809; plant, £85,045; mains, £54,015; cartage of coal, £18,918; making a total of £231,787. The plant at Millbank Street consists of 15 B. & W. boilers with a total evaporation of 75,000 lbs., hand fired and without superheaters; a 208 tube Green economiser; four 44-kw., five 112-kw., and eight 225-kw. d.c. sets, driven by Willans compound engines; three 230-kw., three 400-kw., and two 500-kw. motor generators; a battery of 180 cells with a capacity of 500 ampere-hours at the three-hour rate; boosters, switchboards, feed-pumps, cranes, &c. There are also two condensers, which it is stated are not in commission. To replace this, and to allow for extensions which will have to be made at Millbank Street during the two years which must elapse before the new station is completed, it is proposed to install modern turbo-generator plant, using superheated steam, and running condensing, and 2,890 kw. of motor-generator plant, and a battery. The claim for mains is for the additional feeders to be laid for the new station. Owing to the fact that the new station is not on the river side, the company will have to pay for cartage of coal, and the sum claimed was a lump sum to cover the extra cost until 1931, when the company's electric lighting provisional orders expire.



The hearing of the case occupied nine days between October 26th, 1908, and January 9th, 1909. The witnesses examined were Mr. C. S. Peach, Sir Alexander Kennedy, Mr. W. H. Patchell, Mr. J. Charrington, and Mr. H. H. Hordern for the company, and Mr. H. Steward, Mr. John Slater, Mr. J. F. C. Snell, Mr. C. H. Gadsby, Mr. H. Martin, and Mr. J. H. Rider for the London County Council. Mr. J. A. Simon, K.C., M.P., was umpire, whilst Mr. James Faulkner acted as arbitrator for the company, and Mr. Andrew Young for the County Council.

The arbitrator awarded the company a total sum of £181,371, including £12,500 in respect of the cost of cartage of coal, and £3,100 for other matters agreed upon between the parties. This award makes no allowance for the cost of constructing a subway in which pipes will be laid for conveying condensing water from the River Thames, and it does not include the value of the extra land.

A 200-VOLT 16-C.P. METAL FILAMENT LAMP

MR. STEARN, of the Stearn Electric Lamp Co., Ltd., has sent us a specimen of a 200-volt 16-c.p. 24-watt metal filament lamp. This lamp, which his company expect to have on the market in about a month or six weeks, gives 16 British candle-power, and its efficiency therefore is 1·5 watts per British candle, or 1·35 watts per Hefner candle-power. It will be seen that it represents a considerable gain over the ordinary 60-watt carbon-filament lamp, and gives a smaller unit than the 40-watt 32 Hefner c.p. lamps, which are at present supplied by several makers and are doing such good service. The efficiency is also only slightly less.

Up to the present no life tests are available, but there seems no doubt that it will have the same excellent characteristics in this respect as the tungsten lamps already on the market, viz., a long life and only a very slight drop in candle-power. The extreme fineness of the filament and the consequent difficulty of supporting it may conduce to a certain amount of fragility in the first instance, but, as in the case of the larger metal filament lamps, this will doubtless be overcome as the manufacture is developed.

200-VOLT 16-C.P. 24-WATT STEARN METAL FILAMENT LAMP. Two-thirds Size.

From the illustration which we give of the new lamp, it will be seen that the bulb is only very slightly larger than that of the ordinary 8- or 16-c.p. carbon lamp, and is much smaller and of more convenient shape than the metal filament lamps of larger sizes. The lower candle-power is arrived at by the use of a filament of smaller diameter—a diameter of something like 0·0006 of an inch. At present it does not seem to be possible to "squirt" a metal filament of this extremely small size, and it is therefore first squirted to a larger diameter and then reduced. The filament is about 40 in. long, and it is divided into nine loops in series, each independently supported in a similar manner as the existing Stearn metal filament lamps.

As we have already said, the lamp makers hope to have the lamps ready for delivery in quantities in about a month or six weeks, and in the meantime they are prepared to book orders for delivery in that time. The price will be 5s. per lamp, subject to discounts to the trade.

The Stearn Electric Lamp Co. have also produced a 12-c.p. metal filament lamp, but this is in an earlier stage of development. Mr. Stearn and his company are to be congratulated on being so well to the front in dealing with the metal filament lamp problem.

Telegraph Traffic.—It will be remembered that the cables of the Compagnie Française des Cables Télégraphiques in the West Indies between Paramaribo-Cayenne-Salinas were interrupted some time ago, and the cable going direct from Fort de France, Martinique to Paramaribo broke down on the 28th ult. On the 27th ult. the repairing steamer managed to put the Paramaribo-Cayenne cable into working order again, and on the 2nd inst. the Martinique-Paramaribo cable was also once more working. The Portuguese administration state that all regulations and rates decided upon at the Lisbon conference have been put into force by all contracting States, with the exception of a few, who will undoubtedly follow suit. Among the latter is included France, who has as yet been unable to obtain official approbation.

NEW WESTON INSTRUMENTS

A NUMBER of new patterns of ammeters and voltmeters of the "soft iron" or "electromagnetic" type have just been placed on the market by the Weston Electrical Instrument Co., of Audrey House, Ely Place, London, E.C. Perhaps the most important of the new instruments are a group of A.C. voltmeters and ammeters for switchboard and general use. These are the first soft-iron instruments to be put on the market by the Weston Co., and are the result of a series of experiments extending over many years. The company claim that all the sources of error found in this class of instrument have been either wholly removed or reduced to a minimum, and that the present instruments are thoroughly representative of the high standard which has always been maintained by their instruments.

FIG. 1.—WESTON "SOFT IRON" A.C. AMMETER.

The switchboard instruments are made in two sizes, the diameter of the cases being 9½ in. and 7¼ in. respectively. Voltmeters with a range above 300 volts in the larger, and above 150 volts in the smaller size, are provided with external resistances. The case of each ammeter is provided with an earth terminal which is connected to earth when the pressure exceeds 200 volts, to ensure safety to the user. The ammeters are said to be perfectly safe for use on circuits operating at pressures up to 2,300 volts, but must be used with transformers for higher pressures. The firm do not, however, recommend the practice of bringing to the front of the switchboard any device directly connected to the H.T. circuit. Transformers must be used with ammeters for all circuits carrying over 500 amps., and a value of 5 amps. for the secondary is recommended. The instruments are calibrated with the transformer to read direct. One of the smaller ammeters is illustrated in Fig. 1; this is finished in dead black japan with nickel trimmings in the same style as the firm's well-known D.C. instruments. It is claimed for these instruments that the error, when used for all ordinary frequencies, is entirely negligible; that they indicate the same whether left in circuit for a minute, or permanently; that the error due to ordinary changes in room temperature is negligible; that they are entirely dead beat; and that the divisions are practically uniform on the upper four-fifths' portion of the scale. We have inspected these instruments ourselves, and can vouch for the free and light, and yet quite dead-beat, movement that has been obtained. Figs. 1 and 2 show the uniformity of scale.

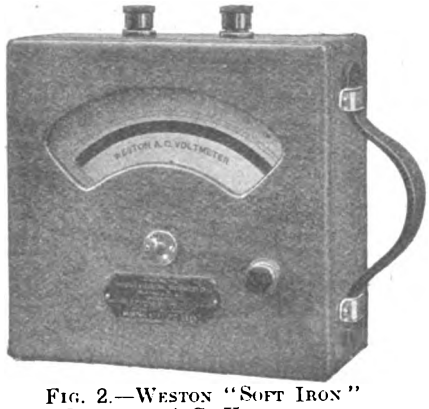

FIG. 2.—WESTON "SOFT IRON" PORTABLE A.C. VOLTMETER.

Besides the switchboard instruments, a group of new portable A.C. instruments have been produced. These include sixteen different ranges of ammeters, five ranges of mil-ammeters, and seven ranges of voltmeters. One of the latter is illustrated in Fig. 2. These instruments have the same properties as the switchboard instruments described above, having practically the same movement. They are light, dead-beat, sensitive, and it is claimed that they can be used on circuits with frequencies of from 15 to 140 cycles without any serious errors. The voltmeters have full scale deflections from 75 to 750 volts, and the ammeters from 1 to 500 amperes. The mil-ammeters range from 75 to 750 mil-ammeters full deflection.

A group of soft-iron instruments for direct-current have also been placed on the market under the name of the "Eclipse" ammeters and voltmeters to distinguish them from the Weston permanent-magnet type of D.C. instrument. These instruments are said to closely approach the permanent-magnet type as regards accuracy, but have not such evenly divided scales. They are, however, much cheaper. The movement is similar to the A.C. instruments, and the same free and dead-beat motion is obtained. They appear to have practically no magnetic lag or hysteresis error, at the normal working pressure, and relatively to the preceding forms of soft-iron instruments, very little lag error at any point of the scale.

In all the above instruments, the pointer is fixed to a spindle pivotted between sapphire bearings, and provided with a vane enclosed in an air chamber. The movement of the spindle is spring controlled, and the zero point is thus unaffected by the position of the instrument.

The appearance of the above instruments is the same as that of the firm's well-known continuous-current instruments, and we are informed that they are of the same class and workmanship. Freedom from friction has been obtained by the use of a very light movement, and by the use of a spindle pivotted between hard jewels, and this ensures sensitiveness and accuracy. The iron cases of the switchboard instruments act as magnetic shields to protect the movements from the influence of stray fields.

BULK SUPPLY AT WILLESDEN

THE Willesden Urban District Council built an electricity works and started supplying the district in 1903. In 1904 they entered into an arrangement with the North Metropolitan Electric Power Supply Co. by which the company bought the electricity works with a view to extending it, and giving a supply over a larger area, at the same time continuing to supply the Willesden Council with electricity in bulk for distribution in their area. This agreement expires in February, 1911, and the Council have already been negotiating a new contract with the North Metropolitan Co., so that in the event of their being unable to arrive at terms satisfactory to them, they would have time to build a new station or make other arrangements for supply. After some negotiations a definite offer was obtained from the company, and this was submitted to Mr. J. F. C. Snell for report.

As the result of this the Council have decided that, subject to satisfactory arrangements being made as to metering the maximum demand, they should continue to take the supply from the company from February, 1911, to February, 1918, at a charge of 20s. per kilowatt of maximum supply demanded per quarter plus £1,000 for the first 4,000 units metered per quarter, plus 0·04d. per unit for all further units supplied. The reason for it being necessary to arrive at some arrangement as to metering the maximum demand is that part of the supply is alternating current and part continuous current. The actual maximum demand may, therefore, be considerably less than the sum of the two maximum demands, as the peaks need not occur simultaneously. It is hoped that a meter will be found which can be connected to the A.C. and the D.C. supply so as to get the actual combined maximum demand.

The Fire on the Metropolitan District Railway.—The report of Mr. A. P. Trotter to the Board of Trade on the fire which took place at Charing Cross Station on the Metropolitan District Railway, on May 24th, has now been issued. It appears that the fire was not of an electrical character, but was due to a spark from a brake block, or from a lighted match or cigarette end, which ignited dust and dirt in a concrete chamber flush with the ballast immediately under the edge of the north platform. The low-pressure mains from the sub-station come out from below the platform into this chamber. The cover of this concrete chamber was made of ordinary plank. It was intended that Jarrah wood should be used, and if that material had been employed, it is probable that the fire would soon have burned itself out, as Jarrah wood is nearly non-inflammable. An iron cover, or indeed a heavy cover, would not be suitable, as it is close to the positive conductor rail, and the space between that and the platform is very limited. The passage between the concrete chamber and the sub-station through which the cables are laid, forms one of the intakes of air into the sub-station, which is powerfully ventilated. The strong draught appears to have fanned the fire and accounts for the fierceness of it. Unfortunately a train running eastward stopped with a motor-car immediately over the feeder supplying the station section. One of the attendants sawed through this cable under great difficulties. If the train had not been allowed to come up to this point, it is probable that traffic might have been resumed after a few minutes. At the time when the current was cut off, no electric damage had been done. The current was cut off for precaution against electrical mishap. No circuit breakers came out either at this sub-station or elsewhere, showing that the electrical arrangements were not interfered with. The fire was fierce enough to melt the lead sheathing of the low-pressure cables, so that the impregnated paper insulation caught fire. Mr. Trotter's conclusion is expressed as follows:—"This accident appears to have arisen mainly from the inadvertent use of ordinary planks instead of Jarrah planks. Owing to the peculiar position of the cover of this chamber I cannot recommend that metal should be used. No danger was involved, and the delay of the traffic was chiefly due to the unfortunate stoppage of a train with a motor immediately over the cable which had to be cut off."

THE SERIOUS CHARGES AGAINST THE WEST HAM ELECTRICITY COMMITTEE

THE Local Government Board inquiry into the application by the West Ham Corporation for sanction to borrow £51,600 for the purpose of the electrical undertaking, was resumed at the Stratford Town Hall on Monday before the Inspector, Mr. H. Ross Hooper. We reported the circumstances of the application, and the evidence at the commencement of the inquiry, in our issue for June 24th, p. 591.

When the inquiry was resumed on Monday, Mr. Elvy Robb put a large number of questions to Mr. A. H. Seabrook, the Corporation's consulting engineer, with the object of arriving at some explanation of the principle adopted at West Ham in charging large consumers, and the manner in which the capital charges are apportioned to each consumer. Mr. Seabrook said that each consumer was charged the capital charges upon the plant appropriated by him, whether the plant appropriated had been installed years ago or specially for the consumer. He could not charge a man next to the works the same as one whose supply involved a £10,000 main. Mr. Seabrook repeated this explanation many times, but Mr. Robb seemed unable to grasp it, although the Inspector did. In the end, after a heated retort and a rebuke by the Inspector, Mr. Seabrook recommended Mr. Robb to read Mr. Pearce's Presidential Address to the Incorporated Municipal Electrical Association at Manchester (ELECTRICAL ENGINEERING, June 24th, p. 581), which, he said, was the latest official declaration on the question of dealing with large power consumers.

With regard to the details of the charge of 0·37d. per unit charged to certain consumers in West Ham, Mr. Seabrook was still unprepared to give the exact details of this, as since the previous inquiry he had been "spring cleaning" with his successor, Mr. Couzens. Asked whether he would be willing to take on further consumers at 0·37d. per unit, Mr. Seabrook said he undoubtedly would; in fact, he was at present negotiating with some firms with this object in view. The boiler capacity of the power-station could be increased by one-half, and the generating plant by 15,000 kw. without additional buildings.

Mr. Robb then touched upon the question of public lighting. According to the published accounts, the net charge for this was 1·36d. per unit. According to the scale for power users, the charge, at the particular load factor should be 0·98d. per unit. The reply was that the conditions of public lighting supply were totally different from anything else on the mains, and to make such an assumption was entirely erroneous.

In order to get at the effect of supplying at 0·37d. per unit, Mr. Robb assumed that all the consumers were 24-hour load people, and worked out the total cost at 0·42d. Upon this reckoning there would last year have been a loss of about £10,000. Mr. Seabrook, however, pointed out that it was incorrect, in the case of such consumers, to estimate the capital charges on the basis of the whole capital expenditure and the costs on the present output. Very much less plant would have been necessary. Throughout Mr. Elvy Robb's somewhat complicated calculation, Mr. Seabrook remarked that he wished to make it clear that he was taking no part in it, as the assumption was quite wrong, and Mr. Robb was getting into a hopeless muddle. The point was eventually left for the Inspector.

Reverting again to supplying at 0·37d. per unit, several questions were asked as to whether a supply had ever been given at a lower figure. Mr. Seabrook said he had not. Mr. Robb, however, took certain figures from the accounts several years ago, which he admitted were incomplete, for the purpose of arriving at the price charged, and, making certain assumptions, got 0·33d. per unit. In this case, it was stated that there were special conditions, but it was not the intention of the Corporation to discuss details of specific contracts, and this answer was repeatedly given to Mr. Robb each time he endeavoured to get such details. The Local Government Board, said Mr. Seabrook, had had all the contracts, and the Council's instructions were that nothing more was to be made public.

In re-examination, Mr. Seabrook said that but for the large power business the price to lighting and smaller consumers would have had to be increased, owing to the reduced revenue in consequence of the use of metal filament lamps. He entirely disagreed with the proposition put forward by the opposition that the capital expenditure should be averaged over all the consumers. It would be the same as a new railway company expecting to cover its capital charges in the first week of running. The general effect of giving such a cheap power supply was that the rateable value of the borough was increased, as works had been specially erected in consequence, whilst, in addition, a considerable increase in employment had been given.

In reply to the Inspector, Mr. Seabrook said the West Ham undertaking had been in existence for ten years. The total capital expenditure was £438,000, and the amount repaid £93,600, or 21 per cent. In his opinion, only a mere nominal reserve fund was necessary after making provision for capital charges, and any other small items in connection therewith. At present it was about £6,000. The Inspector reminded Mr. Seabrook that in Mr. Pearce's address to which he had referred, a reserve and depreciation fund was recommended, in addition to repayment of capital. Mr. Seabrook said the period of loans in West Ham was lower than elsewhere, but on this point, excluding London, the Inspector disagreed, and followed with the remark that already West Ham had been compelled to scrap a power-house, and that the deficits met out of rates in past years, even allowing for the profits this year, amounted to £19,000, for which there should have been a reserve fund. This was admitted, but Mr. Seabrook pointed out that the loss on the original station was part of the capital expenditure, which was now being repaid. This loss, met in this way, was equivalent to writing down capital, which a company in a bad way had to do.

Mr. ROBB, in continuing his speech, which was commenced at the previous hearing, said the opposition of his clients was not in a spirit of hostility to the undertaking, but it was felt there was a very serious error underlying these low estimates for power supply. He did not press for an unconditional refusal of the loan, but asked that the Local Government Board should make it a condition of any sanction that no further contracts at these unremunerative prices shall be entered into; that no existing contracts shall be renewed at existing prices, and that in future contracts for a term of years shall contain proper safeguards in the nature of a sliding scale as to the price of coal, and some further limitations of the liability of the Corporation in the event of failure to supply. The existing contracts were grossly undercut and improvident in their nature, for a single shilling rise in the price of coal might result in very serious losses to the Corporation, who were bound for periods of five and ten years, and in one case for fourteen years. No less than £712 was paid in one year to one company on account of failure to supply, and apparently the statutory liability in this respect had been totally disregarded. The undertaking had been absolutely at the mercy of two extremely able but equally ambitious and sanguine young men, Mr. Littler, the Mayor and Chairman of the Committee, and Mr. Seabrook, the Engineer. It was not right that the ratepayers should be bled to provide a hobby for Mr. Littler or a reputation for Mr. Seabrook. In the absence of the production of the details of the figure of 0·37d., he was justified in assuming that there were no estimates, and that Mr. Seabrook had arrived at it in a haphazard manner. It was admitted by the Borough Accountant that a reserve fund should be provided greater than the present sum available, whilst there should also be some allowance for contingencies. He calculated that the rates had directly contributed £25,000 to the undertaking by the high charge for public lighting, &c., and indirectly many thousands of pounds more in several other ways. For instance, the undertaking had paid no rates, and the full amount during the last five or six years was fully £20,000. West Ham, continued Mr. Robb, was a good example of the worst type of municipal undertaking. It was run on lines of gross irregularity; its financial methods were of the most suspicious and discreditable description; and it was bolstered up by tricks, devices, and shifts at the expense of the general body of ratepayers. His clients were not opposed to municipal trading in the abstract, but they were opposed to this concrete example of it.

Referring once more to his allegation that the sinking fund had been tampered with, Mr. Robb said he challenged the Corporation to give him an assurance that this was not so, and he would at once withdraw the remark.

Mr. MORTEN, K.C., said he would not give any assurances, and was not prepared to discuss the matter.

Mr. STUART RUSSELL, Engineer to the India Rubber, Gutta Percha, and Telegraph Works Co., Ltd., said his company wished to get some assurance that contracts would not be entered into at unremunerative rates. The company was interested in the matter inasmuch as they paid over £7,000 per annum in rates. He accepted the general proposition laid down by Mr. Seabrook that each consumer should bear his share of the fixed and running charges, but he disagreed with the suggestion that large power consumers should only pay the capital charges on the additional plant needed for the power supply. He had worked out what he considered would be the cost of generation at various load factors, and had come to the conclusion that 0·37d. per unit for anything under a 100 per cent. load factor was not remunerative. In his opinion a reserve fund for depreciation to the extent of 2½ per cent. should be made, in addition to interest and sinking fund. In his opinion, if proper provision had been made for depreciation, public lighting had been charged at a proper rate, and rates had been paid upon the undertaking, the profit of £3,800 was in reality a loss of about £12,000.

In cross-examination by Mr. Morten, K.C., witness agreed that the question in relation to the contracts at 0·37d. per unit was as to the proper method of allocating capital charges. If such consumers were only charged the capital charges on their

Digitized by Google

own particular supply, then perhaps 0·37d. per unit might show a profit, but he contended that the capital charge on the whole undertaking must be taken into account.

Mr. W. H. Patchell, late Chief Engineer to the Charing Cross, West End, and City Electricity Supply Co., expressed similar views. A price of 0·37d. per unit could not be substantiated at West Ham, owing to the present capital commitments. It was not fair trading to isolate an extension, and only include the capital charges upon it in estimating the price to the consumer, and disregard the whole of the original capital expenditure. In practical working, 0·37d. per unit was an impossible price. He had worked out that the cost with 8,000 kw. of plant running at 100 per cent. load, would be 0·404d. per unit, even taking certain existing figures to make up the cost, which must of necessity increase with a 100 per cent. load factor. With regard to rates, the Charing Cross Co. were now paying about £4,000 per annum, even though they earned no revenue in the borough.

Cross-examined, Mr. Patchell said he was not aware that the Charing Cross Co. were now supplying a consumer four miles from the power-house with an 80 per cent. load factor at 0·33d. Neither did he know that at Bristol an offer had been made to supply at 0·365d. per unit.

Continuing, he admitted that, in the case of a consumer next to the power-house, he thought it would be legitimate to depart from the principle of making him pay a proportion of the whole capital charges. Some consideration must be had for his position.

Mr. Morten: That is exactly what we have done. When it suits you, you do not mind departing from your principle.

Mr. Robb concluded his case by asking that no part of the loan should be allowed to be appropriated for the purpose of the bankers' overdraft in respect of which litigation was now pending; further, consent to the loan should be conditional upon the sinking fund being put in order and properly invested. No doubt this misapplication of the sinking fund would be explained by saying that the electrical undertaking had been loaned this money out of the Consolidated Loans under the Provisional Order of 1901, but this could not be done without the sanction of the Local Government Board, and this had not been obtained.

On Tuesday, Mr. Drucker, on behalf of the National Electrical Contractors' Association and some local electrical contractors, recalled Mr. Huddleston, manager of Messrs. Siemens Bros. & Co.'s cable department, who produced specimens of his firm's cable to show that that supplied in certain instances by the West Ham Electricity Department as Siemens' cable was, in fact, not so.

Mr. Drucker, in addressing the Inspector, alleged that cable had been sold by the electrical department at prices less than the contractors themselves could purchase it from the makers. With regard to the balance sheet of the sales department, he could not understand why in preparing the profit and loss account the hire of motors had been included, which was the only item showing a profit, whereas the hire of arc lamps, which showed a loss in the detailed accounts, had been left out. A profit of £228 19s. 2d. was shown upon the sales department for the year to March 31st, 1909, and he was told that the hire of arcs, upon which there was a loss, did not come within the sales department, as the price obtained included the supply of current. Neither was any expenditure in respect of the *Electrical Bulletin* charged against the sales department, this being regarded as applying to the undertaking generally, and not to the sales department.

The Inspector, having inspected the profit and loss account of the sales department, said it appeared to him that, had the capital on the hire of motors been borrowed and repaid in accordance with statutory requirements, there was in reality a loss of £543 on the sales department instead of a profit of £228 19s. 2d. for last year.

Mr. Drucker, continuing, referred to the report of Sir Alexander Kennedy upon the wiring department of the Woolwich Borough Council, in which it was stated that this class of business can only be carried out by a contractor with an adequate knowledge of the business and of storekeeping, and that that particular department should be discontinued as soon as possible. This, he said, applied undoubtedly to the West Ham sales department. The real facts and figures they did not know and never would know, but, looking at the matter generally, it was clear that there had been a very great loss. The sum of only £20 had been allocated for rent, rates and taxes in respect of a business with a turnover of many thousands of pounds. Again, no provision was made for bad debts in respect of the 1906 wiring scheme, which it was admitted had entailed a considerable loss. The only part of the sales department which showed a profit was the motors, but for this in reality there was no competition, as the supply of the current and the motors went together, so that the whole of the competing part of the business, so far as the local contractors were concerned, viz., house wiring, and fittings showed a very great loss, which he put at £1,000, for the year to March 31st, 1909.

Mr. H. Holmes, Sales Manager to the West Ham Electricity, said that a good proportion of the cable used in West Ham, both by the Corporation and the local contractors, was of German make. The standard list of quotations issued by the department was for German cable, and the usual profit was 15 per cent. In the case in which it was alleged inferior cable was sold as Siemens, this had arisen through the reference numbers in the stores having got mixed. The original quotation merely mentioned I.R. cable, and was not quoted for as Siemens. The offer to supply Siemens cable was made subsequently.

Mr. Holmes gave his evidence on this point with such readiness, that the Inspector remarked it was peculiar that on the previous occasion Mr. Holmes had a very bad memory with regard to several matters upon which information was required. He even did not know the number of new consumers connected during the year.

Mr. Morten said he thought the remark unjustifiable, as Mr. Holmes had inquired specially into the question of the sale of this particular cable.

Mr. Morten also pointed out to Mr. Drucker, with regard to the charge for rent on the sales department, that the sum of £20 was a special charge for the rent of one room for stores. The general charge for rent was 4 per cent. upon the item for works executed, and was included in this.

A number of ratepayers appealed to the Inspector to recommend the appointment of a Local Government Board auditor to go into the electricity accounts. A member of the Assessment Committee also pointed out that efforts had been made by the committee during the past four years to have the undertaking properly assessed, and that it was not their fault this had not been done.

Mr. Morten, in his speech for the Corporation, said he was quite content to leave the question of the loan in the hands of the Inspector and the Local Government Board, but he was bound to deal with some of the comments which had been made upon the working of the undertaking by the opponents to the application. The opposition of the wiring contractors was solely on the point of competition, and a good deal of aminus had been shown. It would be for the Board to say whether they dealt with the finances concerning motors in the proper manner, and his one comment upon the working of the sales department was that, even if it had been carried out with a far greater loss than had been alleged was the case, the indirect benefit to the electrical undertaking by the additional sales of current had amply justified it. With regard to Mr. Robb's request for a conditional sanction, this really amounted to an endeavour to delay the loan being sanctioned, for it was asked that no portion of it should be used in respect of the legal action now pending between the India Rubber, Gutta Percha & Telegraph Works Co. and the Corporation in respect of the bank overdraft. He had been through the pleadings in this action very carefully, from which it appeared that the action had been commenced as the result of the Local Government Board inquiry, and the suggestion that things should be kept *in statu quo* until this action was settled—which was what it really came to—was startling. The court had to deal with things as they were at the time the action was commenced, and not as they had become afterwards. He ridiculed the suggestion that a sliding scale should be inserted in all power contracts to provide against a rise in the price of coal. This was impossible from the business point of view, and was a risk which all undertakings must take. The question of the proper allocation of capital charges in framing the tariff for power users had been considerably discussed, but to charge an average over the whole of the undertaking was to charge the power user with something which did not relate to his supply at all. The lighting consumer was not hurt in the slightest degree by doing as they had done at West Ham, and even Mr. Patchell's principle of charging every consumer with a proportion of the whole capital costs was to be departed from when a special consumer had to be dealt with. His clients were perfectly satisfied that 0·37d. was a profitable charge. The main point was to look at the accounts of the two years 1907-8 and 1908-9. It was absurd to suggest that there was a loss on 0·37d., seeing that, in spite of the high-priced units having decreased and the low-priced units having increased, a loss had been turned into a profit. This was a full justification for contracts at 0·37d. per unit, apart from the indirect general benefit to the borough of inducing manufacturers to erect works owing to a cheap supply of power being available.

The inquiry then closed.

Improvement in Tramcar Controllers.—The General Purposes Committee of the London County Council have recommended that Mr. T. R. Ireland, rolling-stock superintendent to the Tramway Department, be permitted to take out a patent for an improvement invented by him in the ordinary tramway controller, subject to the condition that the Council do use the patent, should it so desire, without payment. The improvement in question consists of an electrically connected device for interlocking one controller with another, or alternatively arranged to indicate to the motorman any incorrect position and relationship of the reverse cylinders of the controllers, whereby the proper operation of the electric brakes would be affected. The invention has for its object the prevention of accidents such as have occurred recently on one or two tramway systems.

CATALOGUES AND PAMPHLETS RECEIVED

[Readers applying to any of the under-mentioned firms for copies of the catalogues or pamphlets referred to are requested to mention "Electrical Engineering."]

AUTOMATIC TRANSFORMER SWITCH.—A list from the Foster Arc Lamp & Engineering Co., Ltd. (Worple Road, Wimbledon), describes a simple form of automatic switch for saving the no-load losses in auto-transformers by cutting them out of circuit when no lamps are in use. This is claimed to be the only fully automatic transformer switch on the market working without subsidiary batteries. The switching on of the first lamp completes a circuit through the high-tension part of the transformer winding, the lamp and the solenoid which closes the switch and connects the other terminal of the transformer to the mains. This short-circuits the pull on coil, but the switch remains closed as long as lamps are switched on, owing to the action of a holding on solenoid in the lamp circuit.

HOUSE SERVICE BOXES.—A new illustrated list from British Insulated & Helsby Cables, Ltd. (Prescot), gives particulars of a series of T boxes for taking house service connections off street mains. These are made for any combination of concentric twin or three-core main and service cables, and are of the non-disconnecting pattern. Either plummer or ring clamps can be fitted, and all boxes are split to avoid cutting the main cable. Continuity in the sheathing is effected by bonding the lead sheathing of the cables to the cast-iron box by means of a high conductivity tinned copper strip, one end of which is soldered to the lead sheath, and the other end is securely clamped to the box. After all the necessary connections have been made the two halves of the box are bolted together, and the box with the sealing pockets is then completely filled with compound, thereby hermetically sealing the joint.

METERS.—A number of leaflets are being issued by Simplex Conduits, Ltd., dealing with Simplex-Isaria meters of various patterns, of which the company now keep a large stock ready for immediate delivery, and in connection with which they have established at 116 Charing Cross Road a completely equipped testing and calibrating plant. The continuous-current ampere-hour meter is of the motor type, with the field provided by powerful magnets. The movable element is extremely light, and consists mainly of an aluminium disc, which acts as brake, and carries the armature windings. The disc, as well as the commutator, composed of three sectors and suitably connected to the armature windings, are fixed on a vertical spindle. The main current passes through a shunt in parallel with the armature, thus causing the latter to revolve in strict proportion to the load. The alternating-current meters are of very simple construction, and are built on the induction principle, a light aluminium disc being acted on by one shunt and two series coils, and the usual brake magnet being provided. The distance between coils and brake magnet is considerable; besides this the cast-iron wall of the frame acts as a shield. By this means any demagnetising effects are guarded against. From the figures given in the leaflets it appears that the percentage errors at all loads, and the starting currents, as well as the prices, are remarkably low.

ELECTRICAL WORKSHOP APPLIANCES.—The Witton-Kramer Tool and Hoist Co., who have now taken over the manufacture of the electrical appliances formerly made by Messrs. Kramos, Ltd., at their works at Bath, have issued a pamphlet describing some of this apparatus, which includes a series of standard patterns of electric travelling hoist, special forms of electric brake magnets, electric drilling outfits, including single and double magnetic drill posts and flexible shaft tube scrapers for curved boiler tubes, &c.

METAL FILAMENT LAMPS.—A list from Pope's Electric Lamp Co., Ltd. (Willesden), gives particulars of the "Pope" metal filament lamps, which are made in a number of sizes ranging from the 8 c.p. at 16 to 25 volts, to 50 c.p. at 260 volts, and including the popular 16 c.p. (17 watt) 100-volt lamp and the 32 c.p. lamp for 200 to 260 volt circuits.

LIGHTING AND HEATING SUPPLIES.—Three new lists from Messrs. Drake & Gorham (66 Victoria Street, S.W.) deal respectively with Osram lamps, including all the new sizes; the special "Phœnix" series of lanterns for outdoor lighting by metal filament lamps, in which the ample ventilation goes far to prevent undue blackening of the lamps, and the new quartz electric heater, described in another column of this issue.

LOCAL NOTES

ABERDEEN: *Supply to Tramways Company.*—Mr. W. H. Patchell, late Chief Engineer to the Charing Cross, West End & City Electric Supply Co., who was appointed to act as arbitrator to determine the price which the Aberdeen Suburban Tramways Co. should pay the Corporation for electrical energy, heard the case on both sides last week, in Aberdeen, and will give his decision in due course.

BELFAST: *Lighting Abbey Sanatorium.*—An application has been made to the Corporation for a supply of electrical energy for the Abbey Sanatorium, but as this building is outside the municipal area, it would, of course, be illegal to do so. A resolution was proposed at the last meeting of the Corporation recommending that application be made to the Board of Trade for a Provisional Order to include the rural district of Belfast. This was defeated, however.

CROYDON: *Tramway Accounts.*—The accounts of the Tramways Department for the year to March 31st, show a gross profit of £19,693, and after meeting capital charges there is a net balance of £3,294. Reference is made in the report to competition by a service of motor omnibuses which have been started during the year, and in order to counteract this to some extent, 139,112 car miles more were run during the year than in the previous year on one route alone.

DOVER: *Electricity Accounts.*—The accounts of the Corporation's electricity undertaking for the year to March 31st, show a gross profit of £10,047, but after meeting capital charges there is a deficit of £1,980. To this has to be added the adverse balance of £2,147 from last year's accounts, and capital expenditure disallowed by the Local Government Board, bringing the total deficit to £5,318. The number of units sold was 538,270, a decrease of 79,636 over the previous year. The total revenue per unit sold was 4·19d., against 3·96d. in the previous year.

DUNDEE: *The New Generating Station.*—The new station at Stannergate started running last week to supply power to a large jute mill in the town. Owing, however, to delays in the construction of the pumping station at the Fish Dock, the settling tank from which condensing water is taken is not yet complete, and the turbines have had to be worked temporarily non-condensing.

DURBAN: *Free Wiring.*—A scheme for the wiring of private houses, proposed by the Borough Electrical Engineer, has been adopted. The Corporation has recently installed a 750 kw. direct-current turbo-generator, at a cost of £5,240.

EDINBURGH: *Electric Tramways.*—A scheme for the construction of electric tramways between South Queensferry and Edinburgh has been put before the Corporation by private promoters. They point out that owing to the Admiralty operations at Rosyth, some communication of this character is necessary, and that the Kirkcaldy and Dumfermline Councils are willing to extend their systems to Rosyth. The Town Clerk has asked the promoters of the proposed tramways to furnish full particulars, as the Council is disposed to look upon all suburban lines with favour.

GATESHEAD: *Tramway Company's Bill.*—A short time ago an agreement was arrived at between the Corporation and the Gateshead & District Tramways Co. with regard to their Bill now before Parliament, by which the Corporation's opposition was withdrawn. For some reason, however, the Bill has been blocked in the House of Commons, and the Company has asked the Corporation to present a petition to Parliament in favour of the Bill in order to facilitate matters. A resolution to this effect has been carried.

GREYSTONES (IRELAND): *Electric Supply.*—Permission has been granted to the Greystones Electric Lighting Co. to lay their mains underground.

HASLINGDEN: *Electric Lighting.*—The Guardians have accepted an offer by the Rawtenstall Corporation to supply electricity for lighting purposes, at a flat rate of 3d. per unit, subject to five years' agreement, and for power purposes at 1d. per unit, subject to a similar agreement.

HOVE: *Electric Lighting Accounts.*—The accounts of the Corporation Electric Lighting Undertaking in the Aldrington District show a loss of £452 after meeting capital charges.

LEEDS: *Tramways.*—The extension line from Yeadon to Guiseley has now been opened, making complete the extension from Leeds to Guiseley, which was undertaken by the Corporation a short time ago. The extension from the city boundary at Kirkstall first went as far as Horsforth, and afterwards, with the financial co-operation of the district councils of Rawdon, Yeadon, and Guiseley, the extension has been completed to a distance of 9½ miles from Leeds. The line is double track throughout, and has cost £50,000. The three councils concerned have agreed to guarantee the sum of £400 per annum for eleven years.

LONDON: *London County Council: Tramway Employees.*—The Board of Trade having been requested by the London County Council to assist in the formation of conciliation boards covering the employees of the Tramways Department of the Council, it was decided to ascertain by ballot whether a majority of the employees affected are in favour of the scheme. Ballot papers were issued to the employees, and the result of the ballot is as

Digitized by Google

follows:—For, 4,734; against, 759—majority for, 3,975. Steps will now be taken by the Board of Trade to conduct the elections of the employees' representatives for the four sectional boards.

Paddington: Electric Supply Charges.—The General Purposes Committee have decided to forward to the L.C.C. a statement of the negotiations which have taken place with the Metropolitan Electric Supply Co., relative to the transferring of the company's generating station from Amberley Road to Willesden, and to the failure of the effort to induce the company to reduce the price charged for current. The Spring Gardens authority is to be asked if they can assist the Borough Council in any way to obtain the reduction sought for.

St. Pancras: Tramways.—The Works Committee of the Borough Council recommend approval of the plans submitted by the London County Council for continuing the Caledonian Road tramways at Pentonville to Gray's Inn Road, by means of a bridge over the Metropolitan Railway at King's Cross.

Southwark: Electricity Accounts.—The accounts of the Electricity Undertaking for the twelve months ended March 31st last, show a gross profit of £5,939. After deducting interest and instalments of loans, there is a surplus of £849.

LEYTON: *Street Lighting.*—Trials are to be carried out for three months with J. & P., Jandus, Crompton, and Oliver arc lamps.

Metal Filament Lamps.—The Electrical Engineer has obtained from the General Electric Co. a reduction in price from 40s. to 30s. 3d. per dozen for Osram lamps.

MIDDLESEX: *Tramway Extensions.*—The County Council tramways have now been extended from Winchmore Hill to Enfield Town.

MIDDLETON: *Smoke Prosecution.*—The Corporation were summoned last week for allowing black smoke to be emitted from the chimney of the electricity works. Mr. C. H. Norton, the Council's Inspector of Nuisances, gave evidence to the effect that on February 27th black smoke was emitted for 10 min. 31 secs. Notice was served upon the Electricity Committee to abate the nuisance within 14 days, but this was not done, and he had been instructed to take the present proceedings. Mr. S. Pauls, the Corporation Electrical Engineer, said that he was doing all he could to remedy matters, and certain alterations were now being carried out to the condensing plant, which he thought would prevent further trouble. The bench ordered the Electricity Committee to pay the costs of the summons.

OLDHAM: *Electricity Profits.*—The net profits upon the electricity undertaking for the year to March 25th amounted to £3,451.

PRETORIA: *Electric Railway.*—A proposal is to be made to the Pretoria Chamber of Commerce that the Pretoria and Johannesburg Corporations should urge upon the Government the necessity for constructing an electric railway between the two towns.

RIVER PLATE: *Underground Mains.*—The River Plate Electricity Co. contemplate placing all their high tension supply mains underground.

ROSARIO: *New Power-house.*—According to the *Review of the River Plate*, the new electrical power-house of the Central Argentine Railway Co. at Rosario will be inaugurated in August. It will have a capacity of 3,000 h.p. Current will be supplied to the company's workshops for power purposes and also for lighting of stations, &c.

SOUTH AFRICA: *Uitenhage: Electric Lighting.*—The foundation stone of the new electric power station was laid last week, and it is anticipated that the public electric lighting will be completed in about six months.

SWITZERLAND: *Electric Tramway.*—According to the *Board of Trade Journal*, a preliminary committee, represented by M. Antonio Soldini, of Bissone, has been granted an eighty years' concession for the construction and working of an electric tramway from Capolago to Bissone. Work must be commenced within six months from the approval of the plans, and completed within two years. The line will be single-track, and of one metre gauge.

TEWKESBURY: *Electricity Supply.*—The Tewkesbury & District Electric Supply Co. put their new power station into operation last week.

TORQUAY: *Tramways.*—A clause has been inserted in the agreement with the tramway company with regard to the Paignton extension to the effect that if the Paignton Council does not purchase the line in question, the Torquay Corporation may.

WOOD GREEN: *Electric Lighting.*—The scheme prepared by Messrs. May & Hawes, and approved by the Council, under which a supply will be taken in bulk from the North Metropolitan Electric Power Supply Co., involves an expenditure of £31,250, in addition to £2,500 to be expended upon house-wiring. It is proposed to instal 51 public arc lamps, and the estimates of private supply are based upon 450 consumers. The revenue for public lighting is put at £600 per annum, which is £200 more than is at present paid for gas, but there will be five times the light. Upon a basis of 323,000 units sold for private lighting and 74,000 units for public lighting, a gross profit of £2,370 is estimated, with a net profit of £500 after meeting capital charges. Private lighting will be at 4½d. per unit, and other premises, such as shops, public buildings, &c., 4d. per unit. Power will be supplied at 1¾d. per unit. The company's terms are a fixed charge of £1 per quarter per kw. of maximum demand, and 0·7d. per unit for all units up to 25,000 units. There is a sliding scale which brings the price down to 0·35d. per unit for all units in excess of 75,000.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

BATH.—The Local Government Board inquiry into an application by the Corporation for sanction to borrow £11,700 for the purposes of the electrical undertaking, was resumed last week. Upon the suggestion of the inspector the amount applied for has been reduced to £9,470, certain items in the list being regarded as chargeable to revenue account. The details are now as follows: Excess expenditure on previous loans, £2,223; machine tools, £125; new switchboard platform, £162; water-softening plant, £350; automatic stoker, £500; mains extensions, £4,000; house services, £1,500; transformers, £500; meters, £140. In the course of the inquiry Mr. H. R. Hooper, inspector, expressed the opinion that it was a mistake for municipalities to embark upon free wiring.

BIRMINGHAM.—A Local Government Board inquiry was held last week into an application by the Corporation for sanction to borrow £149,350 for the purposes of the electricity undertaking. Of this amount, £100,000 is required for mains, and of this about £20,000 has already been expended; £15,000 is required for high-tension switchgear, £2,000 for transformers on consumers' premises, and the balance for generating plant at the Dale End and Summer Lane station.

BLACKBURN.—The Council have sanctioned the borrowing of £18,000 for the purpose of the electric light undertaking.

DUBLIN.—A Local Government Board inquiry was held last week into an application by the Richmond (Dublin) District Asylum Joint Committee for sanction to borrow £3,800 for the purpose of lighting the asylum by means of electricity. An inspector asked for more figures with regard to the proposal, and the inquiry has been adjourned in order that this may be prepared.

HANDSWORTH.—A Local Government Board inquiry was held last week into an application by the Council for sanction to borrow £4,400 for the purposes of the electrical undertaking. Of this amount £1,000 is required for free wiring. The inspector, Mr. H. R. Hooper, called attention to the speculative nature of free wiring, and questioned the wisdom of the Council in embarking upon it.

ITALY.—H.M. Consul at Naples reports with regard to a project for the employment of the Volturno River for developing electrical energy. A scheme is now before the Naples municipal authorities for the production of about 25,500 h.p. It is proposed to erect a power house at the meeting of the Rochetta and Vandra streams, and a second some nine and a half kilometres further down.

KEIGHLEY.—With regard to the recent application of the Corporation for a loan of £12,800, the Board have indicated their willingness to sanction £2,950 for mains, services, and motors, but with regard to the proposal to erect an alternating-current generating plant, further details are asked for with regard to the prospective demand.

LLANDAFF AND DINAS POWIS.—A Local Government Board inquiry was held last week into an application by the Council for sanction to borrow £2,960 for the purposes of electric supply. An agreement has been entered into with the South Wales Electrical Power Distribution Co. for a supply in bulk at a price varying from 1¾d. to ¾d. per unit, the minimum payment to be £150 per annum.

LONDON: *Southwark.*—Superheaters are to be installed at the Council's power station, at an estimated cost of £570.

Stepney.—The Finance Committee of the L.C.C. recommend the granting of a loan of £7,000 for extension to the Blyth Wharf generating station.

SOUTHAMPTON.—A Local Government Board inquiry was held last week into an application by the Corporation for sanction to borrow £3,000 for the purposes of the electrical undertaking. There was no opposition.

WALTHAMSTOW.—A Local Government Board inquiry was held on Tuesday, into an application by the Corporation for sanction to borrow £1,000 for the electric light undertaking.

YORK.—Mains extensions are to be carried out at an estimated cost of £2,510.

Miscellaneous

ITALY.—The Italian State Railway Department invite tenders by August 10th for a supply of 100,000 linear metres

Digitized by Google

(about 62 miles) of telegraph cable. Tenders, which are open to foreign competition, to Direzzione Generale delle Ferrovie dello Stato, Rome.

PORT OF LONDON AUTHORITY.—Tenders are invited for various materials and stores, including arc lamp carbons and incandescent electric lamps. Particulars from the Secretary, 109 Leadenhall Street, London, and tenders by July 12th.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

E.—Manual training centre at the Roman Road School, Bow and Bromley (£1,196). Builders, J. & C. Bowyer, Ltd., Upper Norwood, S.E.

E.C.—Adaptation of St. Luke's Vestry Hall, 225 City Road, Finsbury, for an insurance company. J. W. Neighbour, agent, 2 Ironmonger Lane, E.C.

N.—Addition to Holloway branch of London & South-Western Bank, Holloway Road, Islington. Architect, A. D. Watson, 34 Great James Street, W.C.

PROVINCES.

BRIGHTON.—Tenders are to be obtained for wiring the Ditchling Road School. The estimate is £225.

CARDIFF.—Proposed new technical institute (£40,000). Education Secretary, City Hall, Cardiff.

EPSOM (Surrey).—Villa hospital (50 patients) at Horton Asylum. W. C. Clifford Smith, Engineer, L.C.C. Asylums Committee, 6 Waterloo Place, S.W.

LEYTON.—Tenders are to be invited by Leyton District Council for the installation of electric light at the Sybourn Street school.

LLANELLY.—Chapel (£2,108). Architect, W. Griffiths, Falcon Chambers, Llanelly.

Y.M.C.A. premises (£3,300). Architect, W. Griffiths, Falcon Chambers, Llanelly.

NORTHAMPTON.—School (£19,500), Billing Road. Surveyor, A. Fidler, Northampton Town Council.

PLYMOUTH.—New church. Architect, Rogers Kitsell, 16 George Street, Plymouth.

SALFORD.—Extensions to the Bradford Dyers' Association works, Liverpool Street, Pendleton.

Tenders are invited for the re-wiring of the Royal Technical Institute. Particulars from Mr. V. A. H. McCowen, Borough Electrical Engineer, and tenders to the Town Clerk by July 12th.

Two New C.B. Telephone Equipments.—The subscribers connected to the National Telephone Co.'s Crosby and Greenock Exchanges have been transferred to central battery equipment, manufactured and installed by Messrs. Western Electric Co., of North Woolwich. The Crosby equipment was transferred at 1.30 p.m. on June 24th, and the Greenock equipment at 4 p.m. on June 26th. Both equipments are of the No. 10 C.B. type, having an ultimate capacity of 1,600 lines; the characteristic features of this type of equipment were outlined in a note on the Great Yarmouth Exchange in our issue of March 11th. The Crosby equipment consists of six subscribers' positions, giving accommodation for 700 lines, and three incoming junction positions; and the Greenock equipment has seven subscribers' positions, accommodating 960 lines, and three incoming junction positions.

Finsbury Technical College Engineering Society.—There was a large attendance of present and past students of the college at the Holborn Restaurant on Tuesday, on the occasion of the annual dinner of the Engineering Society. In the course of the evening, Mr. D. Betts, the Honorary Secretary, read the annual report of the committee. A number of interesting visits were made during the past session, and eleven Papers were read, two of which were by first year students. Among the guests at the dinner was Prof. S. P. Thompson, who, with Mr. P. V. McMahon, replied to the toast of the guests, and referred to the fact that for the third year in succession the chairmanship of the Manchester Section of the Institution of Electrical Engineers had been filled by an Old Finsbury student. Mr. McMahon spoke of the work of the Old Finsbury Students' Association, and in particular of the assistance which had been, and could be, rendered to the younger members by those who were already in responsible positions. The toast of the Engineering Society was proposed by Mr. C. Darling, Lecturer and Demonstrator in Heat at the College, who referred to the service of the society in helping to develop originality in the students. An excellent musical programme had been arranged, and some exceedingly clever rope tricks were shown by Mr. Yaou, a student at the College. The chair was ably taken by Mr. H. D. Gamble, who also contributed to the musical programme.

TENDERS RECEIVED AND ACCEPTED

BURNLEY.—The tender of a local firm has been accepted for the electric wiring of the new Technical School at £1,425.

CHESTER.—The tender of Messrs. Crompton & Co., Ltd., to supply and fix a new switchboard at the Electricity Works has been accepted at £275. This board replaces one which has been condemned by the Home Office.

GRIMSBY.—The tender of Messrs. Sykes & Sugden and Messrs. W. Lucy & Co. have been accepted for the supply of service boxes for two years. The tender of the British Insulated & Helsby Cables, Ltd., has been accepted for a two years' supply of fuse boxes, and that of Messrs. John Wilson & Co. for pipe work.

LONDON: *Metropolitan Asylums Board.*—At the meeting of the Metropolitan Asylums Board on Saturday, the Works Committee reported that the cost of substituting metal filament for carbon filament lamps would be as follows:—North-Western Hospital, £250; Western Hospital, £360; South-Western Hospital, £280; South-Eastern Hospital, £280 (£200 only at present); Children's Infirmary, £480; Downs School, £180; Western Ambulance Station, £30; South-West Ambulance Station, £26; Mead Ambulance Station, £15; South-Eastern Ambulance Station, £40; Central Stores, £60. Prices were obtained for the work from Messrs. Buchanan & Curwen, Speedy, Eynon & Co., and W. J. Fryer & Co. The lowest price, *i.e.*, that from Messrs. Fryer & Co., has been accepted.

Peckham.—The tender of Messrs. R. Bridge & Co. (£135) for the electric lighting installation at the Oliver Goldsmith School has been accepted.

Fire-station Wiring.—The tender of Messrs. G. E. Taylor & Co., of 8 Bush Lane, E.C. (£169) for electric light installation at the Great Marlborough Street fire station has been accepted.

L.C.C. Tramways.—The Highways Committee recommend the acceptance of the tender of Messrs. Dick, Kerr & Co. (£12,055) for the construction of tramways along the Victoria Embankment east of John Carpenter Street, Blackfriars Road, and Southwark Street, exclusive of the supply of rails and special trackwork.

The tender of the Staveley Coal and Iron Co., Ltd. (£7,066), for steam piping tanks, &c., for the final portion of the Greenwich generating station is recommended for acceptance. Ten other tenders, ranging up to £8,495, were received. For the condensing water piping, &c., the tender of the Railway & General Engineering Co., Ltd., of Nottingham, £2,986, is recommended for acceptance. Six other tenders, ranging from £2,617 to £3,236, were received for this section.

LONGTON.—The Council have accepted the tender of Messrs. Tompkinson & Bettelley for extensions to the electricity generating station at £452.

MIDLAND ELECTRIC POWER CO.—The D. P. Battery Co., Ltd., have received an order from the Midland Electric Light & Power Co., of Leamington, to instal and maintain for ten years a storage battery of their LS. 17 type, in replacement of two batteries of another make.

WIGAN.—The following tenders have been provisionally accepted by the Council in connection with the proposed extensions of the power station. Buildings: D. A. Ablett & Sons, £2,475. Constructional steel work: William Park & Co., £720.

The following tenders for cables were received:—Siemens Bros., £8,946; Electrical Co., Ltd., £9,105; Lahmeyer Electrical Co., Ltd., £9,193; W. T. Glover & Co., Ltd. (*accepted*), £9,297; British Insulated & Helsby Cables, Ltd., £9,415; Callenders Cable Co., £9,426; Johnson & Phillips, Ltd., £9,462; Western Electric Co., £9,493; W. T. Henley's Telegraph Works Co., £9,595; Aubert Grenier & Co. (not to specification), £3,918.

The tender of Messrs. Babcock & Wilcox, Ltd., has been provisionally accepted for two boilers, and that of Messrs. Tickle Bros., for pipe-work and condensers, at £1,689.

SALFORD.—The Town Council has accepted the tender of the Tudor Accumulator Co., Ltd., for the supply and erection of a battery, booster, and switchgear, with fittings, cables, connections, and accessories, for £8,809 15s.

WORCESTER.—The tender of Messrs. Heenan & Froude, at £656, for a steel coal bunker and elevator and conveyor at the electricity works, is recommended for acceptance.

Canadian Electrical Association.—The annual convention of the Canadian Electrical Association was held at Quebec last week, where the members and visitors have been entertained by the Mayor and others.

The Imperial Press Conference and Cable Rates.—Mr. Asquith received a deputation of representatives of the Imperial Press Conference on the subject of cable communication between different parts of the Empire. He stated that the attitude of the Government was sympathetic to the reduction of rates, but as regards the cable companies, the means of action at their disposal were very limited. A number of delegates were present at the Imperial International Exhibition on the same day at a demonstration of the Pollak-Virag high-speed telegraph system, when a message was received from Lord Crewe emphasising the benefits of rapid and cheap communication.

Digitized by Google

COMPANIES' MEETINGS AND REPORTS

MEXICAN LIGHT & POWER CO.—A circular has been issued dealing with some reports in connection with the recent accident at the company's water-power station at Necaxa. This accident consisted of a slide into the reservoir of earth and rock, which had recently been sluiced into the dam and had not solidified. No machinery was injured, and the only result of the accident will be to delay the completion of the dam by six months. The operations of the power house have not been affected, nor has the supply to any of the consumers.

NOTTING HILL ELECTRIC LIGHTING CO.—An interim dividend of 3 per cent. and a bonus of 1 per cent., making 8s. per share, is declared upon the preference shares, and 3 per cent. (6s. per share) upon the ordinary shares, for the half-year to June 30th.

ROYCE.—The accounts for the year to March 31st show a gross profit of £1,514, but after meeting debenture charges there is a loss of £925.

ELECTRIC CONSTRUCTION CO.—The balance for the year to May 31st, after meeting debenture interest and crediting depreciation account with £5,000, is £10,730, making with the sum brought forward from last year £12,477. The dividend on the 7 per cent. cumulative preference shares is recommended, carrying forward a balance of £3,687. An increase in the volume of business is reflected in this result, which shows considerable improvement on those of the past few years. The reduced demand for electrical plant owing to the introduction of metal filament lamps, and the general depreciation in trade, has affected the volume of home orders, but this has been counteracted to some extent by an increase in export business.

DELHI ELECTRIC LIGHT & TRAMWAYS CO.—After providing £619 for debenture interest, and debiting the balance of £446 to suspense account, the accounts for the year to October 31st, 1908, show a debit balance of £347.

NORTH METROPOLITAN ELECTRIC POWER SUPPLY CO.—An an extraordinary general meeting on Friday, it was decided to increase the capital of the company by the issue of £200,000 cumulative preference stock at a rate of interest not exceeding 6 per cent. per annum.

PARLIAMENTARY INTELLIGENCE

PROGRESS OF ELECTRICAL BILLS.—The Durham (County) Electric Power Supply Bill was read a third time in the House of Commons on Friday. The Electric Lighting Acts (Amendment) Bill was read a second time in the House of Commons on Friday.

The Gateshead and District Tramways Bill was read a second time before the House of Commons on Tuesday. The Holywood Tramways Bill, the Central London Railway Bill, the North East London Railway Bill, the Folkestone, Sandgate, and Hythe Tramways Bill, and the L.C.C. Tramways and Improvements Bill were read a second time in the House of Lords on Wednesday last week.

WEST KENT ELECTRIC POWER BILL.—The London County Council have withdrawn their opposition to this Bill.

Germany and the New Patents Act.—According to the *Financial Times*, an official representing the Imperial Government in the Petitions Commission of the Reichstag stated during the discussion of the petition presented by the Industrialists Union regarding the new British Patents Law that the Imperial Government had approached the British Government with a view to the removal of the clause enforcing the working of British patents in England, but the British Government had replied that it could only enter into negotiations upon the matter after it had gathered sufficient experience of the working of the new law.

Electricity Supply in Chichester.—In the article in ELECTRICAL ENGINEERING, June 24th, page 569, on the new electricity works at Chichester, the following sentence occurs in reference to the Diesel engine: "Additional interest arises from the fact that the engines are the first designed and made by a British company to be put to work in a public supply station." Messrs. Mirilees, Bickerton & Day, Ltd., the makers of the engines in question, kindly point out that some slight amplification of this is necessary to make the true facts quite clear. They have, as is well known, supplied to a number of public supply stations Diesel oil engines of their own manufacture similar in design to those installed at Chichester, but whereas in these stations, such as those at Birkdale, Oban, and Lewes, the oil engines are used to supplement, or in conjunction with, existing steam engines, in the Chichester station, oil engines are the only prime mover installed, so that it would have been more correct to have said that Chichester was the first public supply station relying entirely on Diesel engines which had been designed and equipped by a British company. We regret that in the same article, by a draughtsman's error, the wrong scale was included in Fig. 1. As will be seen from the dimensions of the engine-room given in the test, the scale should be approximately 1/12th inch equals one foot.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f., port of arrival, quoted on Tuesday night, was £60 to £60 10s. (last week, £60 5s. to £60 15s.).

THE WITTON-KRAMER ELECTRIC TOOL & HOIST CO. This company has recently acquired the entire goodwill of the business of Kramos, Ltd., of Locksbrook Engineering Works, Bath, including their patterns, designs, patents, and trade marks, and are carrying on the manufacture of similar specialities to those of Kramos, Ltd., with the addition of some new designs of monorail electric hoisting machinery, lifting magnets, brake magnets, and portable electric tools.

PLANT FOR SALE.—The Brighouse Corporation have for sale three gas-engine-driven generating sets, a battery of accumulators, and a switchboard. Tenders to the Town Clerk.

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—A petition presented by Messrs. Dick, Kerr & Co., Ltd., for the winding up of the British Aluminium Co., Ltd., will be heard before Mr. Justice Neville in the High Courts on Tuesday next, July 13th.

The petition of Messrs. Harper Bros. & Co. for the compulsory winding up of the North West Electricity & Power Gas Co. was before the High Courts on Tuesday, but was allowed to stand over for a week.

APPOINTMENTS AND PERSONAL NOTES

A presentation was made on Friday last, at the West Ham generating station, of a gold watchchain to Mr. A. H. Seabrook, late Borough Electrical Engineer, on the occasion of his leaving to take up his duties as Electrical Engineer and Manager at Marylebone. Mr. Lloyd-Jones made the presentation on behalf of the Generating Department, and paid tribute to the energy of Mr. Seabrook, and the progress made in many ways under his management.

The salary of Mr. R. M. Carr, Electrical Engineer to the Leek District Council, has been increased from £175 to £200 per annum. It is also recommended that when the electrical undertaking has reached the profit-earning stage, Mr. Carr's salary shall be increased by two further increments of £25 per annum.

Mr. H. F. Foster has resigned his position as Resident Electrical Engineer to the Epsom Council. It is recommended that he should be appointed Consulting Engineer to the Council for one year at a salary of £100.

The Royal Society of Arts.—One of the Society's silver medals for Papers read during the session 1908–9 has been awarded to Herr S. Eyde for his Paper on "The Manufacture of Nitrates from the Atmosphere by the Electric Arc."

The G.B. System on the L.C.C. Tramways.—The G.B. Surface Contact Co. have caused writs to be served on the Star Newspaper Co., proprietors of the *Star* and *Morning Leader*, and also on the proprietors of the *Daily Chronicle*, in regard to alleged libels contained in remarks published in these papers relating to the abandonment of the G.B. surface contact system by the London County Council for the Mile End Road tramways.

The Institution of Mining Electrical Engineers.—The meeting at Glasgow, which had been announced for the purpose of taking steps for the formation of a Scottish section of this new institution, was only very poorly attended, as only seven persons, including the secretary and press representatives, were present. No actual business was therefore transacted. There have, however, been several promises of support in the district. The membership of the Institution up to the present is 221. A further meeting of the Institution is to be held at the Grand Hotel, Manchester, on Saturday next at 7 p.m.

Storage Batteries in Hot Climates.—In view of the exception that has at times been taken to the use of storage batteries in hot climates, D.P. Battery Company, of Bakewell, write calling our attention to a proof of their success in producing plates that will work satisfactorily under these conditions. Cells supplied to the Indian Government some six years ago by this company are still working well, and giving no trouble. No renewals of either positive or negative plates have been required, nor are there signs of deterioration according to the latest accounts.

Electrical Manufacturers and the Electrical Contractors' Association.—At a largely attended meeting of electrical manufacturers of the United Kingdom, held on Thursday, July 1st, at the Hotel Cecil, it was unanimously resolved that the action of the National Electrical Manufacturers' Association in their negotiations with the Electrical Contractors' Association regarding the proposed agreement to give special terms to the members of that Association be endorsed, and that the terms set out in the official *Journal* of the Electrical Contractors' Association, April, 1909, could not be entertained. The meeting was not confined to members of the Manufacturers' Association, manufacturers being invited regardless whether they were members or not.

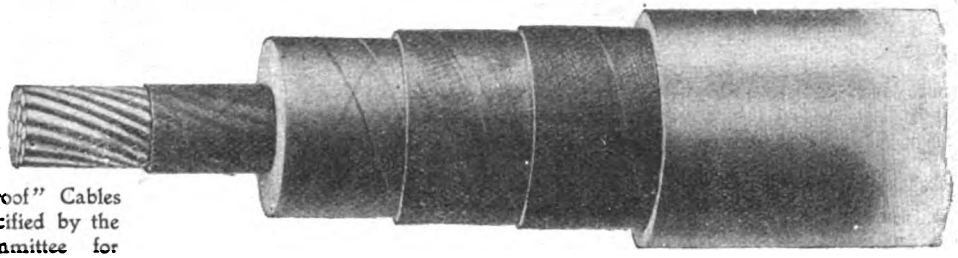
HELSBY CABLES



"OZONE-PROOF" CABLE

FOR HIGH VOLTAGES.

Insulated with Vulcanized Rubber. Either Braided or Lead-covered.

We guarantee our "Ozone-Proof" Cables to stand the pressure tests specified by the Engineering Standards Committee for double the specified period.

For further particulars see Pamphlet H 28.

HARD-CORD BRAIDED TRAILING CABLE

NON-METALLIC COVERING.

Specially designed for Durability and Flexibility.

Made at HELSBY by

BRITISH INSULATED & HELSBY CABLES LIMITED.

Head Office: PRESCOT, LANCASHIRE. **Works: PRESCOT, HELSBY & LIVERPOOL.**

Branch Offices: LONDON, MANCHESTER, GLASGOW, BIRMINGHAM, CARDIFF, NEWCASTLE, DUBLIN, & BELFAST.

"THE STREETLITE"

(The **Ventilated** Street Lantern with **Anti-Vibration** fitting)

IS PATENTED AND MANUFACTURED BY

THE WARDLE ENGINEERING CO., Ltd.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published July 1st, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications. Names in italics indicate communicators of inventions from abroad.

5,781/08. **Insulators for Overhead Construction.** G. W. PARTRIDGE and PHILLIP DAWSON. This invention provides for the indication of the failure of a main H.T. insulator and the insertion of a supplementary insulator to prevent further leakage. The indicator consists of a porcelain tube filled with a bitumen composition, and fitted with insulating plugs at each end. A fuse wire is embedded in the composition, and, when the main insulator fails, the wire fuses and the tube is ruptured or the plugs are blown out to indicate the failure. The device is mechanically fixed to the supplementary insulator, and is connected as a shunt across it, so that when the main insulator fails the shunt is destroyed and the supplementary insulator takes up the pressure. Nine claims, eight figures.

12,326/08. **Speed Regulation of Polyphase Induction Motors.** M. STERN. A method of winding the stator to obtain two speeds by running the motor first as an eight-pole three-phase motor and then as a six-pole two-phase motor, is described. All the elements of the winding are used in each case, but the method is only applicable to motors with eight poles or any multiple of eight. One claim, seven figures.

14,306/08. **Trolley-wire Section Insulator.** A. THODE & Co. The insulating part in alignment with the wires is constructed of wood or other tough material suitable to take up the tension of the trolley-wire, while insulating pieces of hard material such as porcelain are fixed laterally to this. The flanges of the trolley wheel or other collector engage with these pieces so as to lift the groove of the roller from the insulating part to avoid the wear of the latter. Four claims, four figures.

14,695/08. **Collector for Surface-contact and Third-rail Traction Systems.** A. WEST. This collector consists of an endless flexible chain of conducting links run on two sprocket wheels mounted vertically. These wheels are driven at such a speed that the chain runs at the same speed as but in opposite direction to the tramcar or train. Current is collected by contact pieces on the chain, which are pressed on to a live rail by springs, or are drawn down magnetically on to studs in the case of a road tramway. There is no relative motion between the contact pieces and the rail or studs, and so no wear or loss of power due to dragging. To prevent leakage in the case of a surface-contact tramway, the contact pieces are set in a band of india-rubber, which is drawn down and pressed on to the road surface. Two claims, four figures.

5,318/09. **Motor Control.** ALLEGEMEINE ELEKTRICITÄTS-GES. The starting resistances are arranged to be short-circuited by switches operated by solenoids which are connected in parallel across the armature terminals. The resistances are short-circuited successively as the potential across the armature increases. A series solenoid opens a switch in the above control circuit, so that all the resistances are reinserted if an overload occurs. In an alternative arrangement the control solenoids are differentially wound with shunt and series coils, so that the resistances are re-inserted progressively on the occurrence of an overload. Four claims, three figures.

10,057/09. **Cooling of Commutators.** SIEMENS BROS. DYNAMO WORKS and F. F. O'HAGAN. In turbo-generators in which a series of clamping rings are shrunk on to the commutator, it has been found that a blanket of warm air is trapped in the intermediate spaces between the rings, thus checking proper ventilation. To avoid this, the present invention provides for suitably shaped draught-producing passages and recesses in the shrink-rings, which draw out or force in the air more or less radially from or into the spaces between the rings, which thus act as centrifugal blowers. Seven claims, eleven figures.

Opposition to Grant of Patents

7,300/08. **Signalling Lamp.** P. G. SHILSTON. In spite of opposition, the grant of this patent has been allowed. It is for an electric signalling lamp with a shutter consisting of two superposed cylinders, and operated by a solenoid and plunger.

14,554/08. **Vulcanising Apparatus.** P. ALLMAN and G. W. LEESON. The Comptroller has allowed the grant of this patent in spite of opposition, subject to an amendment being agreed to. The invention relates to electrical apparatus for vulcanising tyres, cable coverings, &c. The heating element is a network sheet of resistance wire interwoven with asbestos.

26,588/08. **Wave Length Measurer.** MARCONI'S WIRELESS TELEGRAPH CO., LTD., and H. J. ROUND. Opposition has been entered to the grant of this patent, which is for a wave length measurer comprising a resonating circuit and a crystal with asymmetrical electrical properties. The latter is connected across the condenser in series with a telephone. A variable condenser calibrated in wave lengths is used to adjust the resonating circuit.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. Summaries of some of the more important of these patents will appear in our next issue.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: GRAHAM [Insulator] 15,341/08.

Dynamos, Motors, and Transformers: FYNN [A.C. motors] 10,611/08; MIDGLEY and VANDERVELL [Electromagnetic driving gear for automobiles] 12,738/08; AKT.-GES. BROWN, BOVERI, ET CIE. [Transformers] 13,092/08; ALLMÄNNA SVENSKA ELEKTRISKA AKTIEBOLAGET [Control of compensated repulsion motors] 25,537/08; JOHANNET [Electromagnetic gear for power transmission] 28,438/08; MARCHAL [D.C. machines] 590/09; COUADE [Servo-motors] 2,374/09.

Electric Ignition: LOW [Ignition apparatus] 18,628/08; HOYT and SINSABAUGH [Sparking plugs] 5,895/09.

Electrometallurgy and Electrochemistry: WILLIAMS and GLASSCOCK [Air ozoniser] 17,325/08; BLAGBURN [Fixation of atmospheric nitrogen] 25,535/08; GRUNWALD [Induction furnaces] 5,599/09, and 7,396/09.

Heating and Cooking: BRITISH PROMETHEUS CO., COOPER, and SHARP [Safety devices for liquid heating apparatus] 10,680/08; CUTLER and BARNETT [Liquid heater] 3,028/09; LOWDEN [Cooking apparatus] 12,985/09.

Instruments and Meters: WINN [Meters] 4,666/08; COX [Adjustment of resistances] 18,925/08; BEVIS and PENICUD [Recording instruments] 20,633/08.

Storage Batteries: COWDEROY and REASON MANUFACTURING CO. [Vents for Accumulators or batteries] 2,379/09.

Switchgear, Fuses, and Fittings: HELDBEK [Adjustable lamp suspension devices] 12,736/08; NEWBOULD [Automatic cut-out for tramway systems] 13,048/08; DAVY [Automatic switches] 15,936/08; GARSIDE [Motor Starters] 16,126/08; BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*) [Voltage regulator] 16,299/08; KOE [Switches] 20,708/08; HIRST and COLLINGS [Candle-lamp fittings] 23,116/08; RAASH [Time switches] 27,207/08; DEY [Motor starter] 78/09; WERTHEIM [Sockets for retaining insulating masses] 2,614/09; SCHMAHL and HENDERSON [Fuse-boards] 8,535/09; KRAUSE [Lightning arrester] 9,987/09.

Telephony and Telegraphy: WILLIAMS [Party line selectors and cut-outs] 13,101/08; SMITH and GRANVILLE [Inductance coils for telephone cables] 27,470/08.

Traction: SYKES and W. R. SYKES INTERLOCKING SIGNAL CO. [Operating points and signals] 13,130/08; MUNRO and ROGERS [Operating points and switches] 17,112/08; ROACH [Points and switches] 855/09; O'CONNOR [Rail joints] 3,205/09.

Miscellaneous: KLUPATHY and BERGER [Guiding torpedoes from a distance] 19,825/08; FELTEN & GUILLEAUME-LAHMEYERWERKE AKT.-GES. [Transporting apparatus] 21,957/08; SMITH and HEARIN [Alarm clocks] 22,263/08; BERVILLE [Surgical instrument] 24,815/08; HORST [Electrically heated CO_2 engine] 4,576/09.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

BRÖNDUN [Automatic light ignition] 24,793/08; PONDER and SHOOK [Rail joints] 11,025/09; DELON [H.T. a.c. to d.c. converter] 13,450/09; ALLGEMEINE ELEKTRICITÄTS-GES. [Power transmission systems] 13,798/09.

Expiring and Expired Patents

The following Patents expire during the current week after a life of fourteen years:—

13,380 of July 11th, 1895. **Train Lighting.** M. MOSKOWITZ. To obtain a constant voltage with varying speed, the field-magnets of the generator are provided with differential shunt windings. A change-over device operated electromagnetically maintains the polarity when the direction of rotation is reversed.

13,496 of July 13th, 1895. **Gun Firing on Board Ship.** L. OBRY. A gyroscope, which has a self-contained motor, is arranged to close the firing circuits of the guns when the main axes of the ship are in a horizontal position.

The following are the more important Patents that have become void through non-payment of renewal fees.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: A. HAACKE [Insulating composition] 5,108/00.

Dynamos, Motors, and Transformers: W. YATES and J. B. PENT [Squirrel-cage fan motor] 5,167/00.

Electric Ignition: E. F. BRADLEY and H. EDMUNDS [Electromagnetic switch for engine ignition apparatus] 5,989/03.

Storage Batteries: W. G. HEYS [Charging] 5,918/03.

Switchgear, Fuses, and Fittings: H. BEAU [Conductors and lamp-holders for decorative lighting] 6,315/02; LONDON ELECTRIC SUPPLY CORPORATION and G. W. PARTRIDGE [Oil switch] 6,433/04; C. W. ATKINSON [Overload cut-out] 6,560/04.

Telephony and Telegraphy: H. SHOEMAKER [Transmitter for wireless telegraphy] 6,481/02.

Traction: S. G. BENNETT [Collector plough] 5,154/00.

"ELECTRICAL ENGINEERING," ALTHOUGH THE CHEAPEST ELECTRICAL PAPER (PRICE **1d.** WEEKLY), CONTAINS THE MOST USEFUL AND PRACTICAL ARTICLES, THE BEST ILLUSTRATIONS, AND THE LATEST NEWS. IT IS READ BY THE LEADING ELECTRICAL ENGINEERS, AND IS REGARDED AS A RELIABLE AUTHORITY IN ALL MATTERS CONNECTED WITH THE ELECTRICAL INDUSTRY.

SUMMARY

THE Electric Lighting Acts (Amendment) Bill has been referred to Standing Committee C of the House of Commons. Parties will not be represented by counsel, but a long list of amendments has been sent in by various members of the Committee. (Page 644.)

A DEPUTATION appointed by the Streets Committee of the Corporation of London has visited several Continental towns, and has recommended the use of high-pressure inverted gas lamps, centrally hung, with lowering gear, for the lighting of the City of London. The Streets Committee have not adopted the report, but have merely issued it without offering any opinion on its suggestions. (Page 645.)

ALTHOUGH no announcement has been made, as yet, by the Physikalisch-Technische Reichsanstalt with regard to the recognition of the proposed "International Candle," the German Committee of the International Electrotechnical Commission has expressed the opinion that the Pentane unit cannot be reproduced to the sufficient degree of certainty to render it suitable for an international unit, and have suggested that mutual efforts be made on the part of all countries concerned to establish yet another new unit. (Page 646.)

THE Board of Trade has issued a revised set of regulations under the Electric Lighting Acts in order to avoid overlapping with the recently issued electrical regulations of the Home Office. (Page 646.)

THE chief, and most interesting electrical exhibit at the Imperial International Exhibition is a five-roomed cottage equipped to demonstrate the advantages of electric lighting, cooking, and heating. Other exhibits include a country-house, paraffin-oil-engine lighting installation, telephone apparatus, and an automatic electrically-driven pump for the water supply of large country houses. (Page 647.)

A NEW time limit device for circuit-breakers depending upon the action of an escapement has been brought out. (Page 648.)

AN article on "Bonding and Earthing" by Mr. W. J. U. Sowter deals with the trouble that may arise through not bonding the lead and junction boxes of a H.T. system, and concludes with a plea for absolutely concentric systems and the abolition of tail boxes between concentric cables and transformers or switches. (Page 649).

Digitized by Google

THE following books are reviewed in this issue:—"Heavy Electrical Engineering," by H. M. Hobart; "A Handbook of Wireless Telegraphy," by J. Erskine-Murray; and "Lightning and the Churches," by A. Hands. (Page 651.)

MEETINGS of the Institution of Mining Electrical Engineers have been held in Manchester and Ilfracombe in connection with the formation of local branches. (Page 652.)

THE foundation stone of some new buildings forming part of the Imperial College of Science and Technology was laid by the King on Thursday last. (Page 652.)

OWING to the unsatisfactory condition of the Gillingham electrical undertaking, the Local Government Board have refused to sanction a loan of about £2,000 to cover expenditure incurred since March, 1908. A loan of £2,804 to cover expenditure prior to March 31st, 1908, has, however, been sanctioned. (Page 652.)

WE are able to publish some results of tests of Curtis steam turbines, which show a steam consumption as low as 11·75 and 12·9 lbs. per kw.-hour. (Page 653.)

THE University of Birmingham was formally inaugurated by the King on Wednesday last. The buildings include extensive electrical laboratories. (Page 653.)

THERE is a deficiency of £305 upon the past year's working of the Bristol electricity department.—A gross profit of £279,108 is shown by the accounts of the Manchester Corporation tramways department for 1908–9, and after meeting capital charges, £70,000 are transferred to rates.—Salford Corporation have decided that details of all contracts for electric power shall be entered in the minute books.—The annual report of the Sheffield electricity department for 1908–9 shows a net profit of £2,422.—Swansea Electricity Committee have decided not to entertain a proposal by a company to purchase the municipal electricity works.—A profit of £1,984 is shown by the Wolverhampton electricity department for 1908–9.—A report upon the Cardiff tramway track states that no less than 676 cars per day pass over the central portions of the system. (Page 644.)

CABLES are required at Hereford and Hull; a 500 kw. generating set at Luton; and six double-deck tramcars with equipments, at West Ham, and automatic point controllers at Bradford. The second section of the L.C.C. central car repairing depôt is to be put in hand. An expenditure of £35,000 upon electrical extensions is contemplated at Walsall; and £10,000 upon mains at Wolverhampton. (Page 655.)

A DIVIDEND of $1\frac{3}{4}$ per cent. is recommended upon the ordinary shares of the City & South London Railway Co. After paying 6 per cent. upon the deferred stock for the June half-year, the National Telephone Co. have transferred £150,000 to reserve. At the meeting of the British Electric Traction Co. on Thursday, complaint was made with regard to the depreciation in electrical securities which is likely to follow the passing of the Electric Lighting Acts (Amendment) Bill. (Page 656.)

A LENGTHY report presented to the London County Council on the question of the proper allocation of the cost of street improvements in relation to the tramway accounts, was passed by the Council late on Tuesday night. Hitherto, no definite policy in this respect has been followed, but the report recommends that where the widening is solely necessitated by the tramway, the whole cost of the improvement shall be charged to tramway account. The appointment of a permanent special committee to deal with the question is proposed. An abstract of the report appears on page 659.

THE first of a group of three water-power stations on the Rivers Toce and Devero, in Northern Italy, has recently been put to work. The equipment has a capacity of 20,000 h.p., and the output is taken over a 50,000-volt transmission line to a main sub-station from which a ring of feeders at a lower pressure supply further distributing sub-stations. The two other large stations, when complete, will be connected up to the same main sub-station. (Page 659.)

A LETTER from Mr. A. M. Taylor continues the discussion on cheap units, and Mr. E. Garcke writes complaining of some of the provisions of the Electric Lighting Acts (Amendment) Bill. (Page 660.)

UNDER "Electrometallurgy and Electrochemistry" will be found abstracts of two papers by Prof. S. H. Tucker and Mr. E. G. Thomssen, read recently in America, upon the electrolytic deposition of aluminium, lead, and zinc. (Page 660.)

AMONG the specifications published by the Patent Office on Thursday last, was one by the British Prometheus Co. for a safety device for use in electric-water heating and cooking vessels. When the temperature exceeds a certain amount, a fuse softens and is broken by the action of a weight which also opens the switch. A relay for operating the circuit-breaker in a tramway feeder when the trolley wire supplied by that feeder is broken, is protected by M. G. Newbould, and a continuous-current transformer for supplying constant current from a constant pressure supply is described in a specification by Akt.-Ges. Brown, Boveri & Cie. E. Garside has patented a motor-starting switch of a simple and compact construction, which has some interesting features, and a specification by H. Bevis and J. W. Penicud describes a device for recording the readings of an instrument connected successively by clockwork to a number of different circuits. The appeal by C. H. Stearn and C. F. Topham against the comptroller's decision to refuse their patent for a flat strip support for metal filaments, has been withdrawn. (Pages 650 and 662.)

ELECTRIC LIGHTING ACTS (AMENDMENT) BILL

CONTRARY to the general expectation, the Electric Lighting Acts (Amendment) Bill has been referred to Standing Committee C of the House of Commons instead of a Select Committee. This means that opponents to clauses in the Bill, or to the particular wording of clauses, will not be able to give evidence and be represented by counsel. All amendments must be proposed by the Committee, which consists of sixty-five members. For the consideration of the Electric Lighting Acts (Amendment) Bill the following members have been specially added to the Committee:—Messrs. Bennett, Brocklehurst, Cleland, Cochrane, Conor O'Kelly, James Parker, Samuel Roberts, Esslemont, Falconer, Leverton Harris, Swift McNeill, A. H. Scott, J. M. Henderson, Mr. Tennant, Captain Murray, Sir Edward Sassoon, and the Solicitor-General. Sir Francis Channing is Chairman.

Printed amendments covering four foolscap pages have already been sent in. From these it is seen that several relate to the much-debated wiring clause, the I.M.E.A. having been able to secure a number of members to propose amendments to this clause which would have the effect of allowing municipalities to carry out wiring without the intervention of contractors. A proposed new clause will prevent any electricity supply being given except under the terms of a Provisional Order or special Act. Another aims at preventing the Bill prejudicing any powers at present existing. Notice has also been given of an amendment to exclude electric supply agreements for stamp duty. It will be remembered that although a certain section of the Stamp Act is repealed in the Bill, this is not the section relied upon by the Income Tax Commissioners. The point recently raised that a mortgagee may under the Bill remove electrical apparatus, even though it be on hire, is covered by another amendment. Clause 21 gives the Commissioners of Works power to inspect generating stations to see that proper precautions are taken to prevent the evolution of oxides of sulphur, and generally for the prevention of nuisance from smoke, but an amendment has been handed in exempting the new power station of the Westminster Electric Supply Corporation in Horseferry Road from the operations of this clause.

A letter relating to the Bill from Mr. E. Garcke will be found on page 650.

STREET LIGHTING IN THE CITY OF LONDON

A PECULIAR report has been prepared by a deputation appointed by the Streets Committee of the Corporation of London to inspect the street lighting of some towns on the Continent. The visit was made last March to Brussels, Cologne, Düsseldorf, Berlin, Dresden, Vienna, Munich, and Paris, at a cost of £200, but the Streets Committee prefer not to offer any opinion on the report of their own deputation, nor on the suggestions it contains. This can hardly be wondered at, in view of the remarkable conclusions arrived at, apparently without sufficient data, and on an inadequate knowledge of the subject.

The Deputation consisted of five members, and it was not accompanied by either the City Electrical Inspector or the City Engineer. The conclusions arrived at are as follows:—

(1) That, wherever possible, streets should be lighted by means of centrally hung lamps with lowering gear. This the Deputation think particularly important in the City of London, where the number of obstructions upon the footways in the form of lamp-posts, bins, letter-boxes, &c., is so large

(2) That open spaces should be lighted by means of lamps upon standards, fitted with lowering gear.

(3) That high-pressure incandescent gas lamps with inverted burners should be adopted as the illuminant, but where gas is impracticable, electricity with open arc and flame arc lamps should be installed.

The following note is added:—

We think, however, before suggesting any drastic alterations in the general lighting of the City, that the Streets Committee should be authorised to arrange for some further experimental lighting of the City thoroughfares, and we recommend accordingly.

Thus it is seen that the deputation recommend high-pressure incandescent gas lamps and central suspension with lowering gear, not observing that these two recommendations are irreconcilable. The employment of central suspension with lowering gear for high-pressure gas lamps would, of course, involve the use of flexible tubing, and would be a source of danger to the public; we doubt very much if such a system has ever been tried, except perhaps in the case of one or two isolated instances as an experiment, and it has certainly not been adopted by any of the towns visited by the deputation. The delightful impartiality in suggesting both open and flame arc lamps when gas is impracticable indicates some ignorance of the present state of arc lighting. In these conclusions, it is seen also that no discrimination is made between main and side street lighting, and the claims, both of metal filament lamps and the ordinary low-pressure incandescent gas lamps for this purpose are ignored.

Passing from the conclusions to the more detailed account of the inspection, one naturally endeavours to find the reason for the preference given to high pressure gas. Of the eight towns visited, five have no high pressure lamps, two others have only put in less than a dozen of these lamps on trial, and have no results to report as yet. One town only remains, namely, Berlin, where gas is supplied by the municipality for street lighting at 1s. 4½d. per 1,000 cubic feet, a far lower price than that at which it can be bought by the general public. Electricity supply in Berlin is by a company which has to pay highly for its licence, and it is therefore dear. The following is quoted from the report:—

High-pressure gas lighting is very largely and effectively used in Berlin, 25 miles of streets being lit by 1,531 lamps fitted with upright and inverted burners, two and three burners in each lantern: they are supplied direct from four separate compressing plants at a pressure of about 53 to 78 in. (water-gauge). The newest type of lamps, viz., the "Graetzin" high-pressure inverted lamp, being fitted with three burners per lantern, giving an illuminating value of over 4,000 candles, two burners being extinguished at midnight. The distance apart of these high-pressure lamps is from 90 ft. to 100 ft., and the average height of the lamps above the roadway, measured from the burner, about 19 ft.

Gas manufactured by the municipality is of 12 candle power, unenriched, but tested by the "Metropolitan No. 2" burner, a light equal to 14 or 15 candle-power is obtained—the price of gas was stated to be 1s. 4½d. per 1,000 cubic feet for public lighting purposes. The calorific value (heating power) of this gas is 540 B.Th.U. (British Thermal Units) or 135 calories (gross) [*sic*] This compares favourably with the proposed calorific standard for London gas, viz., 14 candles, 500 B.Th.U., or 125 calories (gross), as inserted in the Gas Light & Coke Co.'s Bill before Parliament this Session.

The gas consumption per hour of a Graetzin three-burner lamp is about 84·8 c. ft., *i.e.*, 28·2 c. ft. per burner. [The other high-pressure gas lamps used vary from 636 c.p. burners at 21·2 c. ft. per hour upwards.] . . . It is stated the mantles at the present time are in use for about nine days. One attendant serves about 50 lamps, that is, he has to clean them, replace the mantles, &c. The extinguishing and lighting are carried out automatically by change of pressure; after midnight, however, it is done by hand.

Very meagre particulars are given of the electric lighting in Berlin. The cost of the largest high-pressure gas lamps is said to be £21 18s. 9d. per annum "inclusive." No corresponding figure is given for the flame lamps in Berlin, and no data sufficient to calculate the resulting illumination for the two classes of lamps.

As regards other towns, the particulars given of the flame arc lighting do not extend very far.

In Brussels and Vienna there were no flame arc lamps, in Düsseldorf only 24, and in Paris the deputation had apparently no time to observe whether the lamps were of the ordinary open or of the flame type. In Cologne 101 out of 426 of the arcs are flames, in Munich 78 out of 900, and in Dresden 301 out of 425. In a few towns the illumination is given, but in no instance is it better than the 0·7 candle foot average with 0·1 minimum recorded for Cannon Street, London; and the illuminations in the gas-lighted streets is not recorded. The costs per annum (including capital charges) are evidently not all on the same basis; for instance, in Cologne this cost per 550- and 690-watt flame lamp is given at £9 6s. 3d., and in Munich the corresponding figure for a 300-watt flame lamp is stated to be £26 19s. 3d.

It is evident that the Street Lighting Committee could have been shown sufficiently good specimens of flame arc street lighting, together with far more useful data as to illumination and cost in London itself and the provinces, if they had put themselves in the hands of their own expert. It is doubtful whether they saw anything better than the arc lighting in Oxford Street for general effect, or than Cannon Street for economy combined with useful illumination. In any case, their recommendation of high pressure gas for main streets as against flame arcs, based only on the Berlin system, where the circumstances are all in favour of gas lighting, will not carry conviction.

The parts of the report relating to metallic filament lamps are chiefly of interest in showing that, with the exception of Dresden, none of the towns visited have yet gone deeply into the question of street lighting with the new lamps.

In Berlin, for instance, out of 198 glow lamps, 177 are Nernst. In Dresden, 437 metal filament lamps are in use, in 30-, 60-, and 330-watt sizes, giving 22, 44, and 260 c.p. respectively. The bulk of the side-street lighting in Dresden, however, is still by low-pressure incandescent gas lamps, giving, it is said, 82 to 109 c.p., and consuming 5 c. ft. of gas per hour.

In conclusion, reference must be made to the unsatisfactory position with regard to the street lighting in the City. While time and money are wasted in waiting for an inconclusive and unsatisfactory report such as this, electric lighting on modern lines is only being carried on in a few hundred yards of streets on a temporary basis, although the test has long ago

Digitized by Google

been sufficient to demonstrate its superiority over any system of gas lighting yet offered to the Corporation when both illumination and economy are taken into account. In the meantime, the Corporation continues to pay £26 per lamp per annum for 380 arc lamps of obsolete design, while a better lamp with more efficient light distribution is being offered them at £17 10s. per annum. As regards the side-street lighting, Mr. Voysey, the City Electrical Inspector, pointed out a year ago that a great saving and better illumination would be obtained by substituting a combination of flame arc lamps and metal filament lamps for the present unsatisfactory gas lighting, but nothing at all has been done.

GERMANY AND THE "INTERNATIONAL CANDLE"

AS we announced in our issue of May 27th, the Bureau of Standards of America has reduced its standard candle by 1·6 per cent., so as to make it the same as the British pentane candle and the French bougie decimale. This alteration was made on April 1st, 1909, and a proposal to call the common unit of light to be maintained jointly by the national standardising laboratories of America, France, and Great Britain the "International Candle" was submitted to the International Electrotechnical Commission.

The German committee, which was formed with the co-operation of the Verband Deutscher Elektrotechniker, were invited to give their opinion on the matter, and have sent a communication to the headquarters of the Commission in London, to the effect that, after consultation with representatives of the scientific and technical interests in Germany, they have come to the conclusion that the proposed unit does not fulfil the conditions that an international unit should do. They state that the latter should be capable of direct and accurate creation with the aid of one definition common to all countries. They admit that the Hefner unit is too small and too red in colour for accurate comparison with modern lamps, but submit that it is easier to reproduce than the other standards. In their opinion, the international light unit of the future must be developed by means of the mutual efforts of the national laboratories of all the countries concerned within the next few years, and they urge the commencement of the necessary experimental work. They point out that international unity in photometry will still be incomplete, even if a common light unit is decided upon, as the units of length will still be different, and illumination will be expressed variously in candle-meters, or candle-feet, according to the standard of length in vogue. They express the hope that, before long, an international system of measurement will be adopted, and in conclusion state that for the present they accept the following figures for the purposes of comparison:—1 Pentane candle=1 American candle=1 Modern bougie decimale=1·11 Hefner candles.

In an article in the *Elektrotechnische Zeitschrift* of June 24th, 1909, is an article by Eugen Brodhun, in which a comparison betwen the Hefner lamp and the 10-c.p. Pentane lamp is made. The author expresses the opinion that the Hefner lamp is a far better unit of light, and that the Pentane lamp lacks the properties of a good unit. Again, in the July 8th issue of the same periodical, in an article entitled "Die Neue Sogenannte Internationale Lichteinheit," the opinion is expressed that the Physikalisch-Technische Reichsanstalt will not be inclined to make further comparisons between the Hefner unit and the new "International" Pentane unit, as suggested by the National Bureau of Standards at Washington, as neither can be reproduced with the certainty required for an international unit. It is pointed out, the new international unit must be capable of definition without referring back to any standard, and it is submitted that all the present units have definitions which do refer back to uncertain standards.

Telegraph Traffic.—The last week has passed without addition to the list of telegraph lines and cables at present interrupted. The conditions of telegraphic communication in Central and some parts of South America are still extremely unsatisfactory; in fact, by now merchants must have become accustomed to "censorship" and "senders' risk," and look upon these telegraphic qualifications as unavoidable. With the unrest in Colombia no doubt further inconvenience will be experienced. It is stated that the Australian Government will shortly introduce a Bill to enable the Commonwealth to seize the shore ends of the Australian cables in time of war.

BOARD OF TRADE ELECTRIC LIGHTING REGULATIONS

AS was indicated during the Home Office inquiry last year into the use of electricity in factories, it has been found necessary by the Board of Trade, in order to avoid dual control in some instances, to amend their own regulations under the Electric Lighting Acts. A revised set of Board of Trade regulations for securing the safety of the public, and for ensuring a proper and sufficient supply of electrical energy, has therefore been issued, which, from July 1st, 1909, except as to so much of any electrical station as was constructed before July 1st, 1908, take the place of the regulations previously made by the Board, and will, after January 1st, 1910, entirely supersede the last-mentioned regulations.

The opportunity has been taken to make a number of verbal alterations, but the most important alteration is that a number of regulations are expressly excluded from applying to "a factory, a workshop, a mine, or a quarry." This addition is made to Clause 1: "Pressure of supply to consumers," (c) 1, where the supply is for incandescent lamps in series; Clause 2: "Introduction of three-wire system into consumers' premises"; and Clauses 9 and 10: "Transformers," where the high-pressure transformer is under the jurisdiction of the Home Office.

Clause 3: "Extra high-pressure supply to consumers' premises" has been reworded, and now reads as follows:—"An extra high-pressure supply shall not be given to any consumers' premises, other than a factory, a workshop, a mine, a quarry, or electric traction works, waterworks, sewerage or drainage works; and no such supply shall be given to electric traction work, waterworks, sewerage or drainage works, except with the consent of the Board of Trade, and subject to such regulations as the Board may prescribe."

The final sentence of Clause 26, "main fuses or circuit-breakers," now reads:—"but no fuse or automatic circuit-breaker shall be inserted in the intermediate conductor of a three-wire system." The words, "where the pressure between adjacent conductors exceeds 125 volts," have been deleted.

It may also be noted that the words, "subject to the concurrence of the Postmaster-General," have been deleted from Clause 34: "Connection of circuits with earth."

The Coal Strike.—In connection with the disturbances amongst the miners in the Midlands, the daily papers state that in some instances colliery property has been surrounded with wire fencing, which will be electrically charged should the men on strike attempt to pass it in order to do damage to the buildings and headgear. It is also stated that most of the electric supply authorities in the affected area have experimented successfully with colliery refuse known as "duff," and have thus been able to avoid a stoppage of their works.

Johannesburg Gas Plant.—The House of Lords last week upheld the decision of the Scotch Courts that the arbitration clause in the agreement relating to the supply of the gas-driven generating plant to the Johannesburg Corporation must be construed according to English law. We gave the full facts of the case in our issue for February 4th, p. 105.

Tests on Metal Filament Lamps.—The results of some tests made by the Physikalisch-Technischen Reichanstalt on some A.E.G. 25 (Hefner) c.p. 110-volt tungsten lamps have been published in the *A.E.G. Zeitung*. It is stated that the lamps had an average life of 3,245 hours, and that after 3,000 hours the candle-power was 80·9 per cent. of the initial value, and the efficiency 1·4 watts per (Hefner) candle. The efficiency at the beginning of the test was 1·15 watts per candle.

New Electric Cars on the North-Eastern Railway.—Six new motor coaches have recently been equipped for the North-Eastern Railway by the British Thomson-Houston Co. The bodies and bogies were constructed at the Railway Co.'s York works. Each coach is equipped with two G.E. 211 motors with commutating poles, both carried on the leading bogie, and controllers, &c., are provided at each end of the cars. A feature of the design of the motors is the way in which it is possible for the armatures to be removed from the shafts in case of damage. Each coach accommodates 64 passengers and weighs 33¾ tons.

Telephone Agreements.—In the King's Bench Division of the High Court last week, the Liverpool Cartowners' Association sued the National Telephone Co. in order to secure a telephone service on the unlimited service rate, whereas the company refused to give a service except upon the message rate system, as is now usual. The action was taken upon an agreement between the Telephone Co. and the Liverpool Corporation, under which the Telephone Co. bound itself to grant unlimited service rates in certain cases; but the Court held that the plaintiffs in this action did not come within the agreement, and dismissed the action with costs.

ELECTRICAL EXHIBITS AT THE IMPERIAL INTERNATIONAL EXHIBITION

ALTHOUGH electrical engineering cannot be said to be well represented at this year's exhibition at Shepherd's Bush, there are one or two exhibits of an electrical nature to which attention should be called. The principal among these is the "Simplex Electric Home," to which we have referred on a previous occasion.

This exhibit, which has been arranged by Messrs. Simplex Conduits, Ltd., of 113–117 Charing Cross Road, London, W.C., comprises a five-roomed cottage, completely equipped to demonstrate the advantages of electric lighting, heating, and cooking. It is situated in the Elite Gardens, and practical demonstrations of electric cooking are given every afternoon and evening. The first and largest room is arranged as a showroom, and contains a representative collection of electrical fittings, including fancy electroliers, standard lamps, table and bracket lamps, and hall lanterns. Among the latest novelties of this class is a neat, adjustable reading lamp, listed at 12s. 6d., with silk shade; a new rose-bowl standard lamp, in which the lamp pillar rises out of a wide rose-bowl, also attracted our attention. This fitting, which is listed at 17s. 6d., inclusive of silk shade, should make an excellent table-centre, and is a most artistic production. A similar fitting with a shallow bowl to act as an ash-tray is also shown. All the lighting fittings are provided with "Simplex" metal filament lamps, for which unusual strength and capability to withstand vibration is claimed. The filaments are supported at the extremity of the loops by coiled carbon springs. A large selection of artistic silk shades, and a number of the effective "Spookie" shades, are also to be seen and bought at the "home." A number of show-boards on the walls illustrate the various stages of the manufacture of "Simplex" conduit and conduit fittings, and some examples of

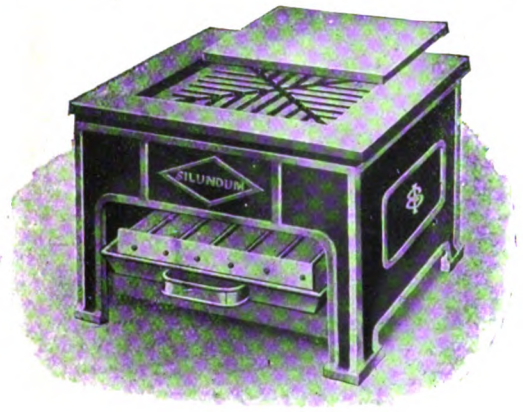

FIG. 1.—SILUNDUM COOKER AND GRILL.

fuse-boards and other wiring accessories are also on view. Among the cooking and heating appliances exhibited in this room are a block-tin kettle taking 400 watts, and said to be capable of boiling its content of 1¾ pints in ten minutes. This is listed at 10s. 6d. A useful egg boiler, or rather steamer, which takes only 240 watts, is also shown. Dental sterilisers, shaving pots, flat-irons (the smallest listed at 8s. 9d., and taking 170 watts), and cigar lighters, are also shown. Among the irons is one adapted for travelling, with one pair of terminals for pressures between 90 and 120 volts, and another for 200 to 250 volts. The heaters exhibited include incandescent lamp radiators of various patterns, and strip convection heaters, in which the heating elements are strips of mica covered with a metallic film. There are also some small motors suitable for driving sewing machines, and examples of the Simplex-Isaria meter, one of those shown is calibrated to read direct in shillings and pence for demonstrating the comparative costs of running metal filament and carbon lamps.

The dining-room and drawing-room are both effectively decorated; the former has a neat central lighting fitting, comprising a pendant cluster for illuminating the table and three lamps near the ceiling for the general lighting of the room. An electric coffee machine, a plate warmer, and a water heater are also to be seen in this room. The drawing-room contains a handsome ceiling fitting with a cut-glass globe, and some pretty candle-lamp brackets. In the bedroom is an electric bed-warmer with a special plug to allow of regulating the heat. A shaving glass with a bull's-eye lamp let into it; a curling-iron heater with an automatic switch, to prevent the heating element being left on; an electric hair-dryer; a water heater; and foot-warmer are also to be seen.

The kitchen, which is wired on the "Simplex" flexible surface wiring system, contains a cooking outfit capable of providing for twenty-five persons, and this is shown in operation every afternoon and evening. The oven, grill, and toaster, which are seen in our illustrations, contain heating elements of silundum, a material consisting mainly of the carbides of silicon and boron. Rods of this material are raised to a cherry-red heat by the passage of the current, and it is claimed that they are entirely unaffected by acids or alkalies, and that they will withstand water, even when red hot. In all cases the rods are protected by cast-iron grids, as shown in Fig. 1, which illustrates a grill made on this principle. When it is not required for boiling water the top is placed over the grid and all the heat is directed on to the grill. This apparatus consumes 1,000 watts, and the toaster illustrated in Fig. 2 also consumes 1,000 watts. The stove shown in Fig. 1 can be fitted with useful side plates to support cooking vessels on. Saucepans, frying-pans, and water heaters with "strip" heating elements are also to be seen. A feature of these is that they can stand on a wooden table without marking it in any way, as all the heat is transferred to the upper portion. The cooking outfit is controlled from one large switchboard with one main switch and a pilot lamp. A hot cupboard for keeping plates warm and an electrically-heated stock-pot are also shown. The oven exhibited

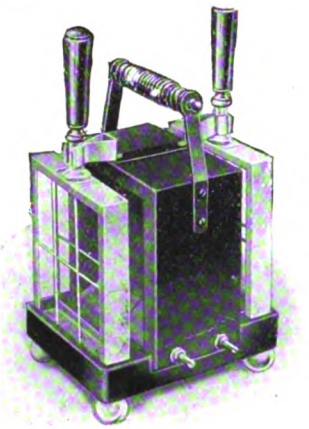

FIG. 2.—SILUNDUM TOASTER.

is of very substantial construction, being of cast-iron, insulated with asbestos packing, and enamel lined. These ovens consume from 1,500 to 3,000 watts. A neat little ceiling fan is also fitted in the kitchen.

Among the very few exhibits distributed about the large building, known last year as the Machinery Hall, are one or two of interest to electrical engineers. Messrs. Tredegar & Co., of 56 Victoria Street, Westminster, S.W., show a complete country-house lighting installation, comprising a paraffin oil engine coupled to a 1½-kw. dynamo generating at 25 volts. A fourteen-cell storage battery and a complete board with charging arrangements is also installed. A large selection of this firm's artistic wooden fittings, both hanging electroliers and wall-brackets, are on view. Messrs. Tredegar supplied all the fittings in the Dutch section of the exhibition, and have also put down a 26-kw. lighting set for the illumination of the "Scenic Aeroplanes," an amusement device not yet opened.

The Western Electric Co. have an exhibit of their well-known telephonic apparatus, and some sample of the "Blue bell" dry cell for local and long distance telephone lines are also to be seen. A new intercommunication telephone fitting for mounting flush with the wall for use in hotels, &c., and a new adjustable telephone bracket for office use are also shown.

A large stand erected for the Norwegian Nitrate Works, Ltd., contains samples of the nitrate fertilisers manufactured at the Notodden works in Norway, and a number of photographs of the power station, the electric arc furnaces, and the absorption plant.

The Pittler Universal Rotary Machine Syndicate, Ltd., have a display of their rotary pumps, steam engines, air compressors, and hydraulic power transmitting gear for motor vehicles. An interesting piece of apparatus shown by this firm is a water pumping set for country houses. This comprises a small 1-h.p. electric motor coupled to a rotary pump. A small quantity of water is always kept in a chamber containing a quantity of air under pressure above the water. When a tap is turned on anywhere in the house the water is forced out of the chamber and the pressure of the air falls; this causes a piston, which is kept up by the air pressure against a spring, to fall, and the motor is immediately switched on. The motor runs so long as the water is kept flowing, but after the tap is closed it only runs long enough (a few seconds) to bring up the air pressure in the chamber to the required amount. The piston then rises and switches off the motor. Another interesting machine exhibited is a combined air compressor and vacuum pump, also electrically driven.

NEW TIME-LIMIT DEVICE FOR CIRCUIT BREAKERS

ON many circuits liable to frequent momentary overloads, it is desirable to introduce a time element before the circuit-breakers shall trip, thus giving continuity of service, without endangering the safety of the plant. A new piece of apparatus for this purpose has been put on the market by the Electric & Ordnance Accessories Co., Ltd., of Cheston Road, Aston, Birmingham, under the name of the "Ordnance" time-limit de-

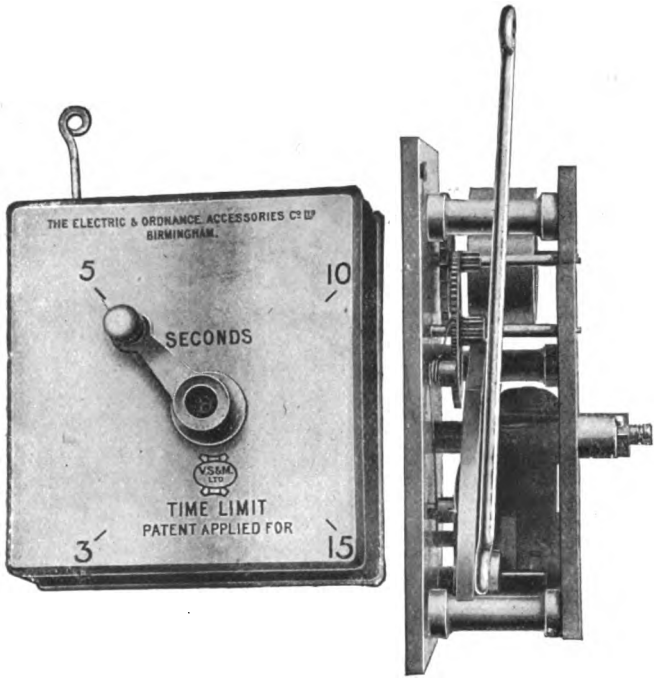

FIG. 1.—THE "ORDNANCE" TIME-LIMIT DEVICE FOR CIRCUIT-BREAKERS.

vice. This consists essentially of a partially toothed quadrant gearing with an escapement, and is illustrated in Fig. 1. The escapement allows the quadrant to move only at a certain speed until it becomes disengaged and so releases the breaker, or until the load becomes normal again. The time element is practically constant for any pull, as can be seen by reference to the characteristic curve shown in Fig. 2, which represents the result of a test taken on the device when set for eight seconds. It will be seen that the best working position is when the pull on the armature is at or above 1 lb. Should it be desirable to release the breaker instantaneously by a dead short-circuit, the

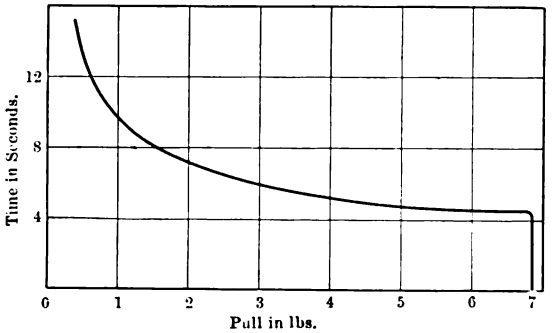

FIG. 2.—TEST CURVE TAKEN WITH THE DEVICE SET FOR 8 SEC.

device can be fitted with an attachment to effect this end. This does not, of course, operate on ordinary overloads when the required time lag is introduced before the circuit-breaker is released. The sudden drop in the curve at just below 7 lbs. pull, represents the point when the attachment for dead short-circuit comes into action. Fig. 3 illustrates a 2,500 amp. circuit-breaker fitted with one of these time limits.

It will be seen by reference to Fig. 1 that the device is calibrated for four time lags, namely, 3, 5, 10, and 15 seconds. This enables the user to choose any time limit the conditions of service may require at the time, and to alter it when he deems it advisable. The instrument can be calibrated for any other periods than those here mentioned. It is claimed that it is extremely simple, compact, and reliable, and that it will always operate after the same interval of time to within a small percentage. The toothed quadrant returns to its original

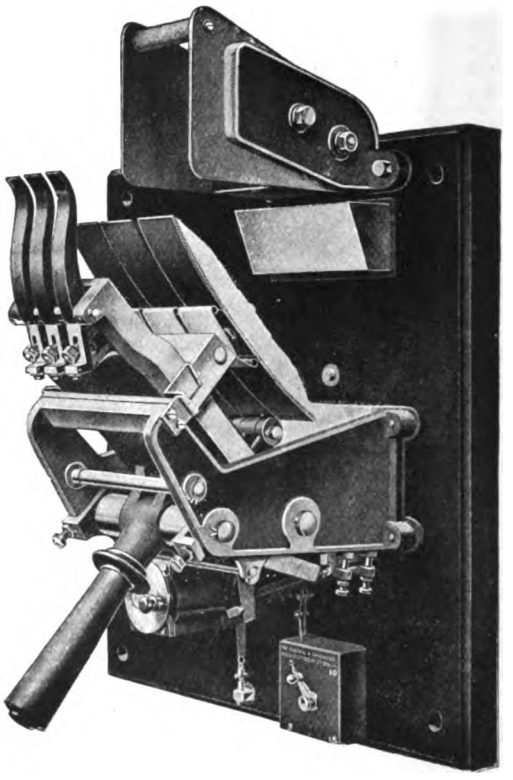

FIG. 3.—2,500 AMP. CIRCUIT-BREAKER FITTED WITH TIME-LIMIT DEVICE.

position immediately any overload has ceased, and is at once ready should a second overload occur, so that the period of the second is not affected by the first.

Proposed Electric Postal Railway in Vienna.—The plans for the proposed underground postal railway in Vienna are now under consideration. This railway will, if constructed, connect up the chief post-office with sixty-four sub-stations and nine railway stations in the city. Letters, newspapers, and parcels will be carried on trains of eight cars running every twenty minutes. The trains will carry no motor-man, but will be operated from the stations, and will travel at a speed of about 20 miles per hour. The subway will be about 25 ft. below the surface, with a height of 5 ft. and a breadth of 4 ft. 6 in. It is stated that a large electrical firm has undertaken to build and equip the line, and lease it to the city and postal authorities.

Electric Traction on the Baden State Railways.—A note on the application of electrical working to the railways in Baden is given in *Le Genie Civil*. The work on the conversion of the "Wiesenthal" Railway, which connects Basle with Schopfheim and Zell, and also comprises a branch to Sächingen, is being taken in hand this year, and both passenger and goods traffic will be hauled by electric locomotives utilising, at any rate at first, the ordinary rolling stock. The system is single-phase, with 10,000 volts, on the overhead conductor, and the equipment is to be supplied by the Siemens-Schuckert Co. Transmission from the generating station at Augst-Wylen on the Rhine is to be three-phase at 6,800 volts 50 cycles, and motor generators at a sub-station in Basle will convert to 10,000 volts single-phase 15 cycles for the supply of the line and its feeders. The two converting sets, which will each be of a capacity of 2,100 kw., will each have a continuous-current machine on their shafts through which the load will be equalised by a buffer battery. Six locomotives have been ordered, which will be employed for both goods and passenger traffic, hauling trains from 200 to 500 tons in weight. These locomotives will have three driving axles with coupled wheels, with loading and trailing axles at the ends. Each will carry two motors of the Siemens compressed series commutator pattern, mounted on the main frame, and thus entirely spring-borne, and driving through cranks and side rods, and an intermediate shaft on to the coupling rods of the driving wheels in the manner employed in a number of Continental designs of locomotive, especially in the three-phase railways of Switzerland and Italy, and more recently copied in America. Each motor will have a continuous rating of 390 h.p., and an "hour rating" of 525 h.p.

BONDING AND EARTHING

By Wm. J. U. Sowter

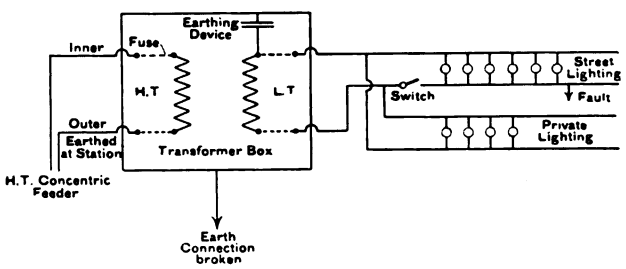
THE necessity of earthing all metal work in proximity to but not forming part of a high-pressure circuit is, of course, well known, but is, nevertheless, a matter which often receives but scant attention. Frequently such connections are made in quite a temporary manner, their existence is afterwards forgotten, and in consequence they are never inspected or tested.

The system in charge of the writer was put down many years ago, when perhaps the necessity of earthing was not fully understood, and the author has, in consequence, had a good deal of trouble to contend with, owing to this omission.

The high-tension concentric feeders are plain, lead-covered paper-insulated, and are laid in puddle clay or marl. This clay is supposed to be a chemically inert substance, and, judging from the condition of the lead covering of the cables, it is so.* Unfortunately, however, the marl has been disturbed in various places at different times, with the result that the lead at such places is badly corroded and, therefore, faults occur from time to time.

If not actually the first paper insulated cables laid for town lighting, these cables were nearly the first.† The section of insulation and lead covering is very much greater than the present standard of the Cable Maker's Association.

The cables are jointed in a great number of places owing to the fact that a good many faults developed soon after laying, due to an unsuitable mixture of oil used in the joint boxes at that time. Since then the boxes have been filled up solid with ordinary pitch. Two mistakes, however, were made: first, the joint was not an ordinary concentric one, but one known—at any rate, locally—as a "butterfly joint"; that is, the core is married and soldered in the usual manner, and the outer conductors are drawn, in some cases, all to one side, and connected by means of an additional piece of copper or cable, and, in other cases, half are laid each side of the inner conductor and jointed; they are then laid in cast-iron boxes, and filled up solid with pitch. The lead covering, where it enters the cast-iron box, is, in some cases, first served with yarn to make a water-tight joint, while, in others, the lead is taken through without, marl being applied to prevent the pitch escaping at the glands while the box is being filled. Here, then, we have two conditions likely to cause, and which have caused, trouble. First, the joint is not truly concentric. Cases have arisen in which the inner has gone to earth in a box, charging the iron casing to full potential above earth. Often such a fault will heal, owing to the pitch melting and re-insulating the defective spot. By this time, however, further damage has resulted. The box has been fully charged, and the lead sheathing has not been properly bonded, making imperfect contact, due, in some cases, to the yarn with which it was originally served, and, in other cases, owing to pitch having run between the iron and the lead when the box was filled originally. There has consequently been a discharge between the iron box and the lead sheathing, burning a hole through the latter. When the paper becomes sufficiently damp, a permanent fault is set up. The writer has known such large currents return to the station, *via* the lead sheathing, that the earth connections (which were then of very small section) were fused.



As no record existed of the number and position of these joint boxes, this state of affairs could only be remedied as the boxes were discovered, and when faults actually occurred. The joints were then re-made and the lead sheathing properly bonded.

Formerly the system was run with an insulated outer, but since the outer conductor has been permanently earthed at the generating station, the system is far safer and cable faults now rarely occur.

The following example shows the danger of neglecting the frequent inspection and testing of earth connections applied to transformers, &c.:—

A transformer in an outlying district was feeding a few private consumers and a circuit of street incandescent lamps, as shown in diagram below.

A short circuit was noticed on the high-tension feeder supplying this and other transformers, which soon cleared itself. An examination revealed the fact that the transformer fuse had blown, due to the breakdown of a lead inside the transformer case which happened to be protected by the fuse. It was also discovered that the whole of the street lamps had evidently been subjected to a very high pressure, as all the lamps were blown to pieces, and the Cardew earthing device had operated. The transformer was tested

for insulation, and found to be in order. The earth connection was examined, and it was found that the earth-wire was corroded away and broken where it entered the pit, and was not readily seen. There was also an earth on the switch wire of the street lighting circuit, and the switch was open at the time.

The inner, when it broke down, evidently charged the case to full potential, and the H.T. current traversed the Cardew earthing device, and passed to earth through the street lamps *via* the fault on the switch wire.

The author has always held that where a concentric system is in use it should be concentric throughout. For instance, concentric cables are often taken into sub-stations or transformer pits, divided up, and rubber tails taken to the transformers. It is surprising the number of distributing centres which are dealt with in this manner, and very few manufacturers of transformers appear to arrange their standard patterns for concentric lead-covered cables. In the former case it is obvious that, should the earth connection of the case of the transformer fail, dangerous conditions may arise without warning; but a proper concentric system entails the occurrence of a short circuit if there has been any failure of insulation, and, at the same time, if the lead sheathing is properly bonded at all joint boxes and at each transformer box, and connected to earth at several points, we have a system which may be regarded as absolutely safe.

* Cases are known in which puddle clay has acted on the lead covering of cables, probably through foreign matter here and there in the clay, the action of which is assisted by the moisture held in the clay.—Ed. *E.E.*

† The famous Ferranti trunk main between Deptford and London was the first, but we believe that the Bray cables were the first lead-covered paper-insulated cables used for town lighting.—Ed. *E.E.*

METAL FILAMENT LAMP PATENT REFUSED

ON January 8th, 1908, application was made by C. H. Stearn and C. F. Topham for a patent for a support for metal filaments consisting of a flat spring attached to the central glass pedestal and provided with a flat hook to engage the filament. A short abstract was published in ELECTRICAL ENGINEERING of October 20th, 1908, after the acceptance of the patent in the ordinary course. The grant of the patent was opposed by the Wolfram (Tungsten) Metal Filament Lamps, Ltd., on the ground that it had been anticipated, and, as we have already announced, the Comptroller, after hearing the evidence, decided to refuse the grant. An appeal against this decision was lodged, but was withdrawn last week.

The number and date of the specification in question is 461 of 1908. It describes and claims a support for an electric lamp filament, consisting of "a spring which is flattened in a plane transverse of the length of the filament, and provided with a

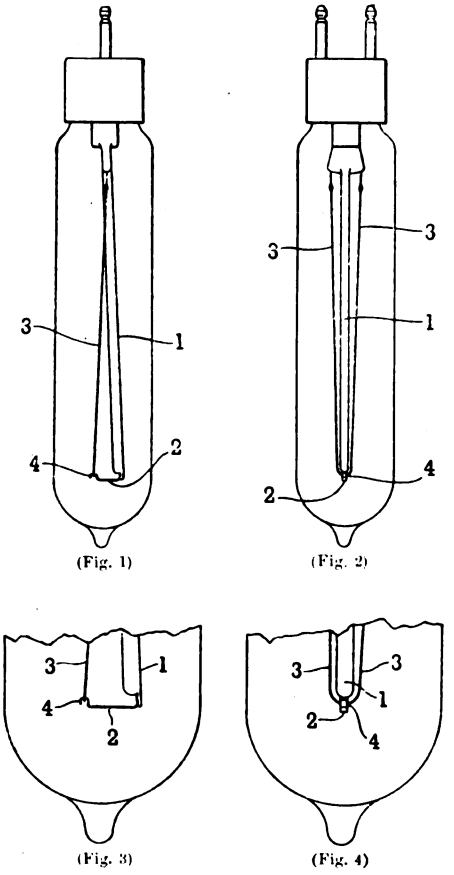

FIG. 1.—THE FOUR FIGURES OF THE STEARN AND TOPHAM SPECIFICATION.

flat hook or loop to engage the filament." The stated objects of this construction, which is illustrated in Fig. 1, are to allow expansion and contraction of the filament consequent upon heating and cooling, while preventing it from moving laterally, and to provide a large radiating surface for the heat passing from the filament to the support. The support is especially applicable to long metal filaments. In the figures, *1* represents the glass pedestal, *2* the flat spring, *3* the filament, and *4* the hook at the end of the support.

In opposing the grant, the Wolfram (Tungsten) Metal Filament Lamps, Ltd., put forward their patents No. 6,803/06 and No. 19,562/07 as anticipations. The first of these claims the use of elastic suspenders for filaments, the dimensions of which are determined by the properties of the filaments and suspenders in question. The suspender may terminate in a hook or eye, and may be made of a thin wire of tantalum or other metal, of several wires twisted together, or of quartz glass. The second specification, No. 19,562/07, claims the method of flexibly supporting a metal filament at two adjacent points. It is stated that the holders consist preferably of a suitable spring material, which readily yields under a pulling strain. In the last two of the figures appended to this specification and reproduced above, the support is shown as a strip *e* of curved section, so that the filament *c* rests upon the edges. Both the patents put forward as anticipations are in the name of the Deutsche Gasglühlicht Aktiensgesellschaft, the patentees of the Osram lamp.

At the hearing before the Comptroller, Mr. P. M. Justice appeared for the opponents, and Mr. G. W. Johnson for Messrs. Stearn and Topham, the applicants. Mr. Johnson pointed out that the Scholvien patent, No. 5,836/05, and the British Thomson-Houston patent, No. 13,596/06 (cited by the opponents in addition to the two patents already mentioned), describe filaments passed over pairs of hooks, and that consequently the Deutsche Gasglühlicht Akt.-Ges. patent could not be considered a "master patent" in this respect. He also contended that the arrangement shown in the last two figures of patent No. 19,562/07 was not specifically mentioned in the claims of that patent. Moreover, the flattening of the spring, the essential feature of the Stearn-Topham invention, was not mentioned in the patent No. 6,803/06.

For the opponents, Mr. Justice argued, in regard to the latter specification, that it would be practically impossible to bend

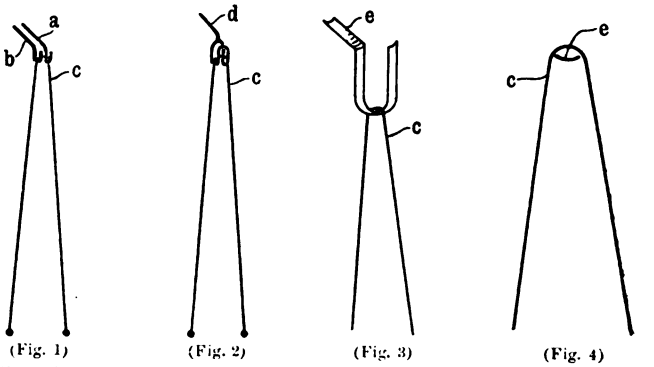

FIG. 2.—THE FOUR FIGURES OF THE DEUTSCHE GASGLÜHLICHT AKT.-GES. SPECIFICATION NO. 19,562 OF 1907.

into hooks the suspenders described without flattening them, particularly when they were made of two or more wires twisted together. The "buckling" referred to in that specification was, he stated, the same as the "lateral torsion," which was to be prevented by the flattened spring described in the applicants' specification. He further stated that as, in practice, a filament supported over a flattened hook would only touch the edges, there was no difference between a flattened hook and the two adjacent supports described in specification No. 19,562/07. The applicants had, he contended, only made a selection of a particular kind of spring.

In his decision, the Comptroller says that his view of the matter is best considered by an inspection of Fig. 4 of No. 19,562/07. He says: "If a straight line is drawn between the points of the lenticular aperture shown at the top of the figure, such straight line would represent a section of the hook the applicants desire to patent. Such a hook would not, in my opinion, be substantially different in construction or function from that claimed in No. 19,562/07. Moreover, it appears to me that, in the process of bending, the section of the hook becomes substantially flattened, and I am of the opinion that it would be difficult to bend it without the occurrence of such flattening. It follows, if I am right, that the hook described in No. 19,562/07 could not be easily made without becoming identical with the applicants' hook." The grant of the patent was therefore refused, and the applicants were ordered to pay to the opponent company the sum of twelve guineas in respect of costs.

Bulk Supply at Willesden.—An error occurred in our article published under this heading on page 634 of our last issue. The price to be paid by the Willesden Urban District Council to the North Metropolitan Electric Power Supply Co. for power in bulk from February, 1911, to February, 1918, will be 20s. per kw. of maximum supply demand per quarter, plus the £1,000 for the first 400,000 units metered per quarter, plus 0·4d. per unit for all further units supplied.

Factory Sites.—The Great Western Railway Co. are doing a good deal to bring before manufacturers the great advantages that are to be gained by the removal of works and factories from highly-rated and congested districts to more suitable places. Amongst the principal factors which have a determining effect upon these migrations may be mentioned the provisions of the new Patent Law; the labour question and rate of wages; and contiguity of ports, coal, and iron fields, and centres of population, and it is claimed that nowhere can more advantageous sites be secured than in the districts served by the Great Western Railway. Those who would obtain further information on sites procurable in the vicinity of London, the West of England, the Midlands, and Wales, are recommended to apply to Mr. T. H. Rendell, Chief Goods Manager, Paddington Station, W.

REVIEWS OF BOOKS

Heavy Electrical Engineering. By H. M. Hobart. 338 pp. 9 in. by 5½ in. 188 illustrations. (London: Archibald Constable and Co.) 16s.

IT is somewhat of a relief to find a work on electrical engineering in general which deals only with the truly engineering aspect of the subject, and does not at the same time endeavour to teach the elementary principles upon which it is based. The book is addressed to engineers and not to students, and its objects are set forth in a most readable preface, which contains an eloquent plea for sound engineering considerations, rather than the "lowest tender" as the governing factor for the details of an electric scheme.

In reviewing so comprehensive a work we can do no more than indicate the general trend of some of its contents, and we will not attempt to give an adequate idea of its completeness. After a short introduction, the general subject of central station economics is surveyed in a chapter entitled "The overall efficiency of generating stations and the relation between coal consumption and outgoing electrical energy," a chapter which, like most of the work, bristles with statistics from actual practice, arranged so that valuable lessons can be drawn therefrom. The succeeding sections deal at some length with steam plant in a thoroughly practical way, and numerous points of importance are insisted upon, which are too often overlooked in central station design.

The chapter on electric generating plant will be read with advantage by engineers who have to prepare specifications of such plant, as the limitations, as well as the capabilities of different classes of machinery are treated in a way much to the point. Mr. Hobart's skill in generalisation from comparative statistics is well shown in the excellent chapter on the design of generating stations, which is suggestive and thoroughly practical, and its interest is greatly enhanced by the many plans and sections of actual power-houses which are reproduced.

One of the most valuable portions of the book is that on high-tension power-transmission lines, where a mass of information of great utility is brought together in both the section on overhead lines and that on underground cables, including an excellent series of curves of approximate costs of lines and cables for different voltages. The data relating to the economics of aluminium as a transmission-line material are particularly instructive, but it is a pity that certain modifications in the figure are required, owing to alterations in the relative cost of copper and aluminium since they were prepared. Following this we have an interesting chapter on the Thury high-tension continuous-current series system, which contains a critical study of Mr. J. S. Highfield's recent Institution Paper on the subject, and points out the serious nature of certain difficulties which may be expected to occur when systems of much larger capacity than those at present at work are equipped. In spite of Mr. Hobart's well-known fondness for continuous currents of higher than ordinary voltages for traction purposes, he is far from favourable to the Thury system for power transmission on a large scale. We naturally turn with some interest to the chapters on electric railway working, in view of the prominent part which Mr. Hobart has played in recent controversy between the advocates of the continuous-current and single-phase systems. Both systems are gone into with the clearness, thoroughness, and wealth of detail which characterise all the author's work; but, welcome as he is to draw comparisons between the two, we certainly think that some of the strong expressions used in the condemnation of single-phase working are out of place in a book of this kind. Thus the use of the expression "single-phase monstrosity" (in bold type), when speaking of the Brighton Railway is a regrettable exhibition of bitter partisanship, which might lead readers who did not know Mr. Hobart to question his impartiality over other matters.

There is one other small matter in which we do not see quite eye-to-eye with Mr. Hobart, and that is, in his use, in the Continental fashion, of the comma instead of the decimal point. We appreciate the author's desire for international uniformity, but we cannot help thinking that the continental reader will not find so much confusion with our decimal point as a British or American reader will on meeting with a use of the comma to which he is not accustomed in a work in the English language.

In spite of these little matters, upon which we have spoken our mind, we have a great admiration for the book before us, including its subject-matter, its arrangement, and—as is almost needless to add, with a technical writer of Mr. Hobart's experience—its indexing.

A Handbook of Wireless Telegraphy. By James Erskine-Murray. Second edition. 370 pp. 8½ in. by 5½ in. 182 illustrations. (London: Crosby, Lockwood & Son.) 10s. 6d.

THE appearance of the second edition so soon after the first, besides speaking eloquently for the popularity of the book, has made it possible for the author to bring the work very completely up to date without altering the general scheme and without making serious breaks in the connectedness of the treatment. One of the chief additions made imperative by recent developments is nearly a whole chapter on the various methods of generating electrical oscillations by means of the unstable electric arc. Another addition consists of an account of Zenneck's treatment of the equations of propagation of electric waves over surfaces of differing conductivity, for example, sea-water, wet ground, and dry ground; together with Hack's interesting diagrams of the electromagnetic field near the earth's surface as waves pass over it. Thirdly, a most important addition is a number of pages descriptive of the measurement of the damping factors of oscillatory circuits. Strange to say, the author gives the reader no indication whatever, how, when, or where a knowledge of the damping factor is useful in real practice—the method of measurement is, as it were, thrown down before the reader for him to pick up and apply to wireless telegraphy if he can. The author has not taken the opportunity of remedying a thing we ventured to complain of in our review of the first edition. "A reader may finish the book with only the very vaguest notions of the size, weight, and electrical dimensions (such as number of turns, &c.) of those parts of a wireless station which are usually concealed in screwed-up boxes." Rough notions of these quantities can easily be obtained by any author, and would prove a great mental assistance to the practically-minded reader.

Lightning and the Churches. By Alfred Hands. 92 pp. 5½ in. by 8½ in. Illustrated. (London: J. W. Gray & Son.) 1s.

IN this little book, which is addressed to the non-technical reader, Mr. Hands gives a great deal of interesting information regarding damage done by lightning to churches, and shows, by an investigation of numerous examples, how, in practically every case, where serious damage has been done, either the building has been entirely unprotected, or such protection as has been relied upon has been obviously faulty. He emphasises the necessity of each case being carefully considered by a man of experience, and points out the advisability of periodical testing of lightning conductors. The author's extended experience as senior partner of a firm of lightning conductor experts gives his views great practical value, but it is a little disappointing not to find more detail in the book regarding the actual good and bad points in lightning conductor construction, about which there is a good deal of difference of opinion; in connection, for example, with iron *versus* copper, solid *versus* stranded conductors, &c. The theoretical considerations as to the discharge are too sketchy; its oscillatory nature is not sufficiently emphasised, nor are such points as the need of avoiding sharp bends in lightning conductors brought out prominently enough.

THE INSTITUTION OF MINING ELECTRICAL ENGINEERS

A MEETING of this Institution was held on Saturday last at the Grand Hotel, Manchester, for the purpose of forming a branch for Lancashire and Cheshire. About 24 persons were present. Mr. H. C. Crawford (General Electric Co., Ltd.) presided, and called upon Mr. J. G. Williams, the General Secretary, to give details as to the progress of the Institution. Mr. Williams said that ten weeks ago the membership was only 30, and now it had increased to over 200. It was the intention to have about six monthly meetings during the winter for the reading and discussion of Papers. The Papers would be read by all the branch secretaries simultaneously, and discussed the same evening, and the discussions printed and issued to members the week following, and the author's reply the week after that. The intention was to complete the formation of branches in each mining centre, to hold a general committee meeting in August, and to commence the first year of the Institution in the first week in September with a general meeting of a holiday character. Arrangements are already being made to visit a group of collieries in the N.E. part of England. Mr. Williams will receive for the time being all subscriptions until the General Committee meeting, at which it will be arranged as to each branch acting independently as regards expenses, and reserve a percentage of amounts received to the General Committee.

It was then decided to approach certain general managers of collieries to act as president, and Mr. J. H. C. Brooking was appointed as vice-president, for Council representative Mr. W. Bolton Shaw was appointed, and for the local secretaryship it was unanimously decided that Mr. P. D. Coates, 55 Ennismore Street, Burnley, Lancs., should continue his kind efforts in this capacity. A Local Committee was also elected, and it was decided to meet again for the first meeting of the session on September 11th, 1909, at the same place, at 6 o'clock.

At a meeting held on Thursday, the 7th inst., at Ilfracombe, under the chairmanship of Mr. H. J. F. Stewart, at which several mining engineers and managers from the Gloucester and Somerset coalfields and the Cornish tin mines were present, it was resolved to form another local branch of the Institution. The chairman gave a detailed explanation of the origin, aims, and progress of the Institution, and referred to the various organising and administrative points which would be settled at the next general meeting. He remarked that the Southern Section would cover a very large district, but as a matter of fact its mineral area was almost entirely confined to the Western counties, and London, therefore, as its centre, was quite out of the question. On the other hand, this part of Devon, was about midway between the Gloucester mines and the wheals of the Duchy. Altogether the number of applications already received was entirely satisfactory, the members and associates showing a total to date of 230. It was agreed that the hon. secretary should be asked to approach Mr. R. Hood Haggie with a view to his election as president of the section. A small provisional committee was elected, of which Mr. H. J. F. Stewart consented to act as chairman until the general meeting in September.

South African Exhibition.—Instead of an international exhibition, which it was proposed to hold in Cape Town on the opening of the first South African Federated Parliament, it has now been decided to hold a South African Exhibition, in which there will be an electrical section.

Wireless Telegraphy.—A large number of new wireless stations are being established by the French Government. Besides those at Ushant and Porquerolles, stations have been erected at Marseilles, Algiers, Boulogne-sur-Mer, and Nice. The Naval Department are establishing stations at Dunkirk, Cherbourg, Brest, Lorient, Rochefort, Portotorres, Ajaccio Cran, and Bizerta.

It is probable that a complete wireless system connecting the Canary Islands with Europe, Cape Colony, and South America, will shortly be installed. Santa Cruz de Tenerife is to be the main station in the islands and communication is to be established with all the adjacent islands; with Cadiz, and thence to Paris; with Casablanca, and thence to Paris direct; with Pernambuco, and thence to Buenos Ayres; with a station in Senegambia, probably Dakar, and thence to Cape Town. The work is to be undertaken by two companies, one in Paris, and the other in Madrid. A site for the installation in Santa Cruz de Tenerife has been granted by the authorities, and Las Palmas has followed suit, not only with a grant of land, but also with a loan of 20,000 pesetas. The conditions of the loan are that it is to be repaid in 10 years, and the station is to be handed over to the Spanish Government at the end of 20 years. It is said that communication between Tenerife and Cadiz will be established shortly. If the distance between Tenerife and Pernambuco proves too great for practical success, an installation will be set up in St. Vincent. The proposal for the establishment of an Imperial wireless system recently published in *The Times*, has been taken up by the press in New Zealand, where the scheme is thought important and practicable.

THE IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

THE new buildings forming a part of the final development of the scheme of the Imperial College of Science and Technology at South Kensington, of which the King laid the foundation stone last Thursday, will make provision for considerable extensions to the mining, metallurgical, geological, and engineering sections in the college. The building will occupy a site at the corner of Exhibition Road and Prince Consort Road, extending from the existing premises of the City and Guilds of London Institute, to the Royal College of Music. As is well known, the Central Technical College of the City and Guilds of London Institute, the Royal College of Science, and the Royal School of Mines, were all incorporated into the scheme for what is now called the Imperial College of Science and Technology, so that the engineering section of the new buildings which are at the end adjoining the City and Guilds Institute can practically be looked upon as extensions to its accommodation.

This portion will include a hydraulic laboratory, 180 ft. by 46 ft., the equipment for which will be provided by Mr. C. Hawkesley, and two large top-lighted courts, 112 ft. by 102 ft., and 112 ft. by 42 ft. respectively, which will be devoted to testing and other engineering plant, besides lecture rooms, drawing and examination rooms for various engineering departments, such as railway and traction engineering, naval architecture, and bridge construction. The mining department will also be very extensive, and will include the equipment for studying methods of ore extraction, supplied by the Bessemer Memorial Committee, and among the laboratories in an adjoining court will be one devoted to electro-metallurgy, as well as roasting and smelting furnaces, and laboratories for wet and dry assay, with balance-room, lecture-room, laboratories for micrography, pyrometry, &c., and the equable temperature room. The geological department will be on the second floor.

The whole group of buildings will be electrically lighted, and current will be obtained from a generating station on the premises, as well as steam and hot water for heating purposes. As was the case with the buildings on the south side of Imperial Institute Road, which accommodate the Physical and Chemical Departments, the buildings are from the designs of Sir Aston Webb.

ELECTRIC LIGHTING LOAN REFUSED AT GILLINGHAM

THE Local Government Board has granted sanction to the Council to borrow the sum of £2,804 for the purposes of its electrical undertaking, but has refused to sanction the remainder of the £5,000 for which application was made. During the recent Local Government Board inquiry Mr. H. Ross Hooper, the Inspector, made some very pointed remarks upon the undertaking generally, and the Board recommends the Council to engage a highly qualified electrical engineer to investigate the working of the undertaking and report upon the best means of reducing the annual loss which is at present being incurred. The loan now sanctioned relates to expenditure incurred during the year to March 31st, 1908, and the greater part of the remainder of the £5,000 has also been spent since that date. If the Local Government Board refuses to alter its decision, the charging of the amount to the rates will, it is said, involve an addition of threepence in the pound.

The consideration of this communication from the Local Government Board was the cause of a very stormy meeting of the Council last week, the result of which was the passing of a resolution asking the President of the Institution of Electrical Engineers to give the names of six gentlemen from whom the Council could select one.

Tax on Electric Lamps in Germany.—The German Finance Bill, which passed its third reading on Saturday, contains, among its provisions the tax on illuminating apparatus which was referred to in a note in ELECTRICAL ENGINEERING of June 24th, page 593. There has been considerable opposition to the tax, which affects both gas and electric lighting, and includes charges upon incandescent lamps, arc lamps, carbons, and gas mantles. It is estimated by the Government that the yield will amount to 20 million marks per annum.

The Brussels Exhibition.—At a meeting last week in Newcastle, at which Lord Lytton and Mr. Wintour were present on behalf of the Royal Commissioners for the Brussels Exhibition, the Newcastle and Gateshead Chamber of Commerce passed a resolution approving the steps taken by the Board of Trade for the organisation of the British exhibits. It was announced that Messrs. Armstrong, Whitworth & Co., would make an important exhibit in the machinery section. Some particulars of the arrangements for the British exhibits were given in ELECTRICAL ENGINEERING, July 1st, p. 621.

TESTS ON CURTIS TURBINES

IN a discussion on Mr. Blackman's recent Paper on "Steam Turbines," reported in our issue of July 1st, some figures were given of steam consumptions of Curtis turbines, differing from those which had previously been quoted by Mr. J. P. Gregory, of the British Thomson-Houston Co., earlier in the discussion. We understand, however, that Mr. Gregory's figures were tests of very recent machines, and practically all of them official tests, whereas those mentioned by the other speakers were on old machines built some years ago. The machines at Chicago, for instance, mentioned by one of the subsequent speakers, were of the old two-stage type, built five or six years ago, and, as a matter of fact, they are now being converted into exhaust steam turbines. As Mr. Gregory mentioned in his remarks, a 9,000 kw. machine at the Chicago Commonwealth Edison Company station, showed a full load steam consumption of 12·9 lbs. per kw.-hour. This machine is a five-stage machine, and was erected and tested in the early part of 1907, the test being taken on site by Professors L. B. Breakenridge and Storm Bull. The actual figures, which we are now able to publish, of the whole range of tests on this machine, are as follows :—

K.W.	Steam pressure lbs. per sq. in.	Super-heat deg. Fahr.	Vacuum (30in. Bar).	Steam consumption lbs. per kw.-hour.
5,374	162	133	29·43	13·15
8,070	197	116	29·55	13·0
10,156	176	147	29·47	12·9
12,108	182	148	29·34	13·05
13,900	198	140	29·31	13·6

Mr. Gregory also mentioned the excellent tests made recently on a 4,000-kw. A.-E.-G.-Curtis turbo-alternator at the Rummelsburg generating station of the Berliner Elektrizitätswerke, Berlin. The tests were made by independent engineers, and we are able to give the following particulars from an article in the *Zeitschrift für das Gesamte Turbinenwesen*. The speed of the set is 1,500 r.p.m., and the three-phase generator is rated at 4,000 k.v.a., 6,000 volt, 50 cycles. The exciter is direct coupled, and has a capacity of 25 kw. The turbine is provided with a surface condenser, and a vacuum of from 97 to 98 per cent. is regularly maintained. All the auxiliaries are driven by 500-volt, three-phase motors from a special transformer. Steam is supplied at a pressure of 180 lbs. per sq. in., superheated to 332°C. The guaranteed steam consumption was 14·3 lbs. per kw.-hour, at full load, with 95 per cent. vacuum, and steam at 180 lbs. per sq. in. and 300° C. For half-load, the guaranteed figure was 15·9 lbs. per kw.-hour.

The steam consumption was measured by collecting the condensed steam. A full-load test with 174 lbs. steam pressure, an admission temperature of 150°C., and a vacuum of 97·3 per cent., gave a steam consumption of 11·94 lbs. of steam per kw.-hour, the total output being 4,252 kw., including 12·7 kw. from the exciter, and 59·4 kw. used by the condensing-plant motors. The consumption per kw.-hour of available three-phase energy worked out at 12·15 lbs. of steam, but as most published figures refer to the total output of the turbine, these must be compared with the figure of 11·94 lbs. The consumption reduced to the guarantee conditions of 95 per cent. vacuum, and admission temperature of 300°C., works out at 13·4 lbs. per net kw.-hour, *i.e.*, considerably less than the guaranteed figure of 15·9 lbs. At three-quarter load, the figure corresponding to the 11·94 lbs. at full load, was 12 lbs. per kw.-hour, and at half-load 11·75 lbs. per kw.-hour. It is remarkable that the consumption was maintained so constant over this very wide range of load; it appears that it was rendered possible by careful design, and steam regulation by closing some of the admission nozzles at low loads.

The British Thomson-Houston Co., Ltd., inform us that repeat orders for vertical Curtis steam turbines have been received from the Liverpool Corporation for their Lister Drive station, where three of these sets have been giving thorough satisfaction. The company have also sent us the following list of orders received for Curtis turbines of the horizontal pattern for exhaust and mixed pressure :—

The Cleveland & Durham E.P. Co. (Teesbridge), a 1,500 kw. 2-stage plain exhaust 3-phase H.C.; Fife Coal Co., two 750 kw. 3-phase mixed pressure; Earl Fitzwilliam Collieries, a 350 kw. mixed pressure A.C.; Wath Main Colliery, a 500 kw. plain exhaust A.C.; Braidwater Spinning Company, Ireland, a 750 kw. mixed pressure A.C.; Bolsover Colliery Co., a 500 kw. A.C. plain exhaust; Lothian Coal Co., a 560 kw. mixed pressure D.C.; Shirebrook Colliery Co., a 500 kw. mixed pressure A.C.; Bolckow Vaughan, a 750 kw. mixed pressure A.C.; Carrongrove Paper Co., a 1,000 kw. high pressure A.C.; Oriental Timber Co., a 750 kw. mixed pressure A.C.; Watford U.D.C., a 500 kw. high pressure A.C.; Hakota E.L. Co., a 1,000 kw. high pressure A.C.

INAUGURATION OF BIRMINGHAM UNIVERSITY BY THE KING

ALTHOUGH the actual ceremony of inauguration of the University of Birmingham by the King was only performed on Wednesday last week, many of the departments, and among them the electrical engineering section, have been practically in full swing for some time. The whole of the engineering department has been equipped within the last five or six years, and is divided into departments for civil, mechanical, and electrical engineering, but as is unavoidable, especially in the last two, there is some overlapping. The civil engineering department is under the direction of Prof. S. Dixon, and its equipment is very complete, particularly as regards the hydraulic and testing branches, the latter of which includes what is said to be the largest testing machine in the world, capable of applying stresses up to 300 tons to specimens 28 ft. in length. The mechanical engineering department, under Prof. F. W. Burstall, includes the power station and various workshops, with a foundry and laboratories. The power station, from which light and power is supplied to the whole of the building, includes five boilers of various types, an independent gas-fired superheater, and a Mond gas producer. Steam engines have been presented by Messrs. Willans & Robinson, Messrs. Belliss & Morcom, and Messrs. Ruston, Proctor & Co. There is also a small steam turbine, several gas and petrol engines, and a Diesel oil engine. A battery complete with a motor-driven charging set, boosters, &c., has recently been installed in connection with the lighting of some of the newer buildings.

The electrical engineering department is under the control of Prof. Gisbert Kapp, and the laboratory equipment comprises junior and advanced laboratories, dynamo-room, photometric laboratory, and testing room. Very complete arrangements are made for the supply of continuous and alternating current at various frequencies, as may be required in the different laboratories. The junior laboratory is 45 ft. by 47 ft., and this adjoins a photometer gallery and a ballistic galvanometer room. Near by are another galvanometer room, lecture rooms, library, a research laboratory, professors' rooms, and stores. In the balcony above this is a photometric equipment for arc lamps, and below is the senior electrical laboratory, containing a large number of machines and apparatus. Two large batteries are provided, and a row of motor generators of about 30 kw. capacity each, by various makers and of various descriptions, from which continuous and alternating currents at various voltages and frequencies can be obtained. There is also an automatic battery booster, supplied by the Compagnie de l'Industrie Electrique, of Geneva. A number of different types of motors, rotary converters, &c., are provided on the test beds, and several transformers are arranged for the carrying out of tests. The switching arrangements are very complete, and the standardising rooms permit of instruments being readily checked.

A "Loaded" Anglo-French Telephone Cable.—The heading of this note does not refer to a new type of submarine mine, but to the decision of the British Post Office to lay across the English Channel a telephone cable fitted with inductance or "loading" coils. In the July number of the *Post Office Electrical Engineers' Journal*, it is stated that by the use of these loading coils it will probably be possible to increase the speaking value of the cable more than threefold. In some general remarks on the subject, our contemporary says that the quality of the iron wire used in forming the coils is not at all in accordance with what, at first sight, might be thought to be the right kind, *i.e.*, soft iron charcoal wire is highly inefficient, wire of the nature of steel being best.

Electric Lighting Provisional Orders.—The Board of Trade report respecting the applications to and proceedings of the Board under the Electric Lighting Acts, during the past year, shows that only 13 applications for provisional electric lighting orders were made. Of these 11 were granted, the refusals being in the case of Chipping Norton & District Electric Light & Power Co., with whose financial arrangements the Board of Trade were not satisfied, and the Skelmorlie & Wemyss Bay Gas & Electric Supply Co., whose application for an order for portion of the parishes of Inverkip and Largs was opposed by the local authorities. At Walton-on-Naze an order was granted to the Coast Development Corporation, in spite of the refusal of the local authority to consent to the application. In one or two cases, the areas applied for were reduced. Since the date of the last report, 12 orders have changed hands.

LOCAL NOTES

BATH: *Electricity Accounts.*—The accounts of the Corporation electricity department for the year to March 31st shows a loss of £384, after meeting capital charges. This brings the accumulated deficit up to £1,660, but as the Corporation have in hand the forfeited deposit of Mr. Schenk of £2,500, they are able to show a balance on the right side of £529.

BECKENHAM: *Council and Wiring Contractors.*—The Electrical Engineer has presented a report dealing with increasing the number of consumers. He suggests that an endeavour should be made to work in co-operation with the wiring contractor in order to arrange for a better system of advertising in the local Press. A suggestion to open a show-room is not to be entertained.

Charging for Electricity Supply.—The Council have under consideration a proposal by the Chairman of the Electricity Committee, Mr. A. H. Dykes, to institute a system of charging a fixed sum per lamp per annum in the case of electrical energy supplied to small houses.

BRIDLINGTON: *Electricity Accounts.*—The accounts to March 31st show that the deficit has been reduced from £275 in the previous year to £188.

BRISTOL: *Electricity Accounts.*—For the twelve months ended March 25th last, the gross receipts were £81,389, and the working expenditure was £38,225. After payment of interest on loans and instalments of principal, and also putting aside £2,825 for renewals, there is a deficiency of £305 on the year's working. The balance at credit of reserve for renewals fund is £18,506, and the unappropriated balance carried forward is now £6,230

CARDIFF: *Report on Tramway Track.*—We reported a few months ago that Mr. Howard Smith, of London, had been retained by the Corporation to examine and report upon the condition of the tramway track. He has now presented his report, and states that the construction of the permanent way has been well carried out on right lines with sound materials and good workmanship. The suitability of some of the paving materials, however, he considers open to question. The physical and working conditions of the Cardiff track Mr. Smith regards as unusually onerous, and not favourable to low cost of maintenance. With regard to the life of permanent way, Mr. Smith does not agree with the period of 25 years, usually put forward, except under extremely favourable conditions. Where the conditions approach the other extreme, the rails might require renewal every two or three years. The average density of car service in Cardiff is greater than that of any fairly comparable system in the kingdom, as many as 676 cars per day passing over the central sections, with the result that in some places the life of the rails had come to an end, and the wheel flanges were rubbing on the floor of the groove. Rail corrugation has been, in Mr. Smith's opinion, responsible for much damage to the permanent way, and he makes a number of recommendations for dealing with the unsatisfactory condition in which the track now is.

CHINA: *Chungkung.*—A Consular report states that the Chungkung Electric Light Co., a Chinese concern which started operations on a small scale last year with 220 sixteen c.p. lamps, is considering tenders for the erection of a larger station, for which a site has been secured outside the Tai Ping Men.

CLECKHEATON: *Gas v. Electricity.*—The Bradford Corporation supply gas in certain outlying portions of Cleckheaton, but there is great dissatisfaction with the price. The Cleckheaton Council has been asked to extend their electric supply mains into these districts.

Electricity Accounts.—The accounts of the electricity department for the year to March 31st show a net profit of £51.

CUCKFIELD: *Electricity Supply.*—The Hayward's Heath Electric Supply Co. propose to apply for an electric lighting provisional order for this district.

DERBY: *Extension of Electricity Area.*—The Electric Lighting Committee ask the Council to apply for a Provisional Order to extend the limits of electricity supply to Littleover, Markeaton, Darley Abbey, Breadsall, Chaddesden, Alvaston and Boulton, Normanton, and Sinfin Moor.

DONCASTER: *Bentley Sewerage.*—The Rural District Council, at their last meeting, approved of a scheme of main sewerage for Bentley Colliery Village, and decided to apply to the Local Government Board for a further loan to carry out the work. Electric pumping will be adopted, current being obtained from the Bentley Coal Co. The engineers for the scheme are Messrs. D. Balfour & Son, of London and Newcastle-on-Tyne.

EASTBOURNE: *Electricity Surplus.*—The Elective Auditors, in their report, say that they are of opinion that the electric light balance in hand on the reserve and depreciation fund is somewhat large, viz., £11,486 17s. 3d., and that some of it should go to relieve the rates, but after an explanation given them thereon by the Borough Accountant, they desired to leave the matter in the hands of the Council.

KIRKCALDY: *Tramway and Electricity Accounts.*—The tramway accounts for the past financial year, show a gross profit of £4,716, as against £4,923 last year, and after payment of interest, sinking fund, and depreciation, there is a deficit of £209. The traffic receipts have fallen £600 during the year, this being due to depression in trade. During the year 3,798,053 passengers have been carried, and by the Wemyss cars 868,310, against 4,264,419 and 609,480 respectively last year. The electric lighting accounts show that the current for the tramways has been charged at 1½d. per unit, as against 1¼d. last year, thus reducing the revenue under this head by £950. The gross profit carried to the net revenue account is £3,599, and after payment of interest and sinking fund charges, there is a net profit of £240. The combined undertakings show a net profit of £30.

LARNE: *Public Lighting.*—The Council have sealed an agreement with the Larne Electric Light Works, Ltd., for the public lighting of the town for three years from August 1st, 1909.

LONDON: *Battersea: Arc Lamps on Hire.*—On June 9th the Council decided to apply to the L.C.C. for a loan of £1,500, for providing consumers with arc lamps and motors and wiring premises therefore on the cash and hire-purchase systems. As to await the sanction of the Central Authority will cause delay, £500 is to be taken out of current revenue to inaugurate the scheme.

LOUGHBOROUGH: *Electricity Works.*—At the last meeting of the Town Council, it was stated that, in consequence of following the recent advice of Mr. J. F. C. Snell in regard to their excessive coal consumption, they had been able to effect a saving of about £300 per annum in this respect. A special sub-committee has been appointed to look after the Electrical Department, instead of having a Joint Gas & Electricity Committee as formerly. The sales for June show an increase of nearly 100 per cent., compared with June, 1908.

MANCHESTER: *Tramway Accounts.*—The report of the tramways department for the year to March 31st states that the aggregate length of single track open for traffic, including the lines over which the Corporation has running powers, is 181 miles. The total revenue was £784,555, against £769,072 in the previous year, and the working expenses £508,071, against £500,022. Adding bank interest, the gross profit is £279,108, against £271,153. Capital charges, &c., absorb £128,267, and the sum of £76,754 is added to reserve, renewals and depreciation account, £70,000 to relief of rates, and the balance to street improvements, &c. The number of car miles run was 17,316,753, against 16,974,955, and the passengers carried were 155,011,884, against 151,477,138. The revenue per car mile was 10·874d.

MONTREAL: *Public Lighting.*—At the end of last year there was a dispute between the Corporation and the Montreal Light, Heat & Power Co. with regard to public lighting, which was then charged at 60 dollars per lamp. The company informed the Corporation that it could no longer supply light at this figure, and offered to make a contract at 75 dollars per lamp. No agreement was come to, however, and it was arranged that the company should continue the public lighting without an agreement, the charge to be temporarily at cost price. The company have now presented a bill for the first five months of the year, in which they state that the cost price of supplying public lighting has worked out to about 95 dollars per lamp, and they offer the Corporation every facility for inspecting the books, &c., to satisfy themselves that this figure is the correct one.

MOTHERWELL: *Electricity Accounts.*—The municipal electricity accounts for the year to May 15th, states that 26 new consumers have been connected to the mains, making a total of 584 consumers, the total connections being equivalent to 94,648 8-c.p. lamps. The number of units sold increased from 1,964,683 to 2,169,267. Works costs have been reduced from ·65d. to ·60d. per unit. Total expenditure amounted to £6,655, against £6,619, and the income to £12,486, against £12,039. After meeting capital charges there is a net profit of £229. Bad trade and metal filament lamps are the causes given for the slow progress.

SALFORD: *Contracts for Power Supply.*—The Special Committee recently appointed to consider the question of whether full details of all contracts entered into for power supply should be placed upon the minute books has now reported. There are two reports, the majority being only six to five. The minority object to being obliged to pass the minutes of the Electricity Committee without knowing what they contain. The minority report was passed.

SHEFFIELD: *Electricity Accounts.*—The annual report of Mr. S. E. Fedden, City Electrical Engineer and Manager, points out that, although the revenue has decreased, there has been an increase in the output. The lighting sales have decreased by 196,175 units (£4,251), of which 113,175 units are traced to the use of metal filament lamps. The total output increased by 728,993 units, whilst the income was less by £819. After meeting all expenditure, and meeting capital charges, there is a net surplus of £2,422, which makes the accumulated surplus £18,751, from which £10,000 will be added to renewals fund. The total income was £77,728, and the expenditure £25,025.

Digitized by Google

SOUTH SHIELDS: *Tramway Energy.*—A dispute arose a short while ago with regard to the account rendered by the Electricity Committee for tramway energy. It was subsequently found that the meters were defective, and after recalibration the amount of energy consumed was found to be 1·37 units per car mile. After negotiations, however, the two committees have agreed upon a basis of 1·52 units per car mile. The result of the rearrangement is that the tramways undertaking will be able to show a profit for the past year, but that the electrical department will show a loss.

STOCKTON: *Power Supply.*—The renewal of the contract with the Forge Works of Messrs. Head, Wrightson & Co. for electric power was the cause of some discussion at the last meeting of the Council. The firm in question take about one-third of the total output of the electricity works, and the Committee agreed to supply at ⅝d. per unit, the works being kept running all day. An amendment was carried, however, fixing the price at ¾d. per unit, in spite of the fact that the firm have definitely refused to entertain this price.

SUTTON: *Electric Lighting Charges Increased.*—The South Metropolitan Electric Tramways & Lighting Co. have given notice of a proposed increased charge for energy in October next. It is stated that the present flat rate of 3½d. will be increased by something like 60 per cent. The Clerk was asked to look into the powers of the company under their order.

SWANSEA: *Offer to Purchase Electricity Works.*—A letter was read from Mr. Edward Harris, solicitor, acting for clients whose names were not disclosed, suggesting proposals for the transfer and reorganisation of the local electric supply service was read at the last meeting of the Electricity Committee. A factor of increasing importance in industrial expansion, the letter pointed out, was the provision of a cheap power for the operation of machinery, and it would be found that the offer of electric power at a low price had frequently been the decisive condition. It was submitted that the Swansea electrical undertaking did not at present contribute in any appreciable degree to the industrial progress of the district, and Mr. Harris's clients were prepared to undertake the financial and other responsibilities of the electric supply, to extend the system of distribution, and substantially to reduce the cost of current to present and prospective consumers, both for lighting and power purposes. The method of transfer suggested was for the company to acquire from the Corporation its present undertaking, and become responsible for the payment of the instalments of loan charges payable in respect of all debts contracted by the Corporation in connection therewith, and undertaking to extend the system of distribution and at the same time substantially to reduce the price of current. It was confidently expected that the important reduction in power rate would check the present unfortunate tendency for local works, &c., to put in their own separate plants, and would stimulate the settlement of new industries in the district. It was unanimously decided not to entertain the proposal.

WEST BROMWICH: *Electric Supply Discounts.*—In future a discount of 2½ per cent. will be allowed to lighting and power users.

WEST HARTLEPOOL: *Supply to Tramway Co.*—The Corporation have objected to the Cleveland & Durham County Electric Power Co. supplying the tramway company within the borough, and the latter have applied to the Board of Trade to decide the point at issue.

WIGTOWNSHIRE: *Trunk Telephone System.*—The County Council has been informed that from the estimates of the cost of extending the trunk telephone system to Wigtownshire, the capital expenditure would only be justified if a larger number of subscribers were forthcoming than seemed likely to be obtained. The Postmaster-General, however, has offered to canvass the district thoroughly before giving his final decision.

WIMBLEDON: *Electricity Supply.*—The Council is to apply for a Provisional Order to supply electricity in Maldens and Coombe.

WOLVERHAMPTON: *Electricity and Tramway Accounts.*—The accounts of the electricity undertaking for the year ended March 31st show a net profit of £1,984, after deducting £1,417 authorised by the Council to be applied in aid of the Improvement Rate. The £1,984 is to be placed to the credit of the reserve fund. The total reduction in revenue on the tramcar service is £1,797; on the other hand, there is a decrease on the working cost per mile on the Lorain surface-contact system of 0·135d. per car mile down to 6·374d. There was a gross profit on the account of £17,048, and a net profit of £5,906. Of this amount £4,505 is to be placed to the credit of the reserve or renewals fund, which now amounts to £26,590.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

HEREFORD.—Mains are to be extended at an estimated cost of £587. The Local Government Board have sanctioned the borrowing of £7,038 of the loan of £8,000 applied for, made up as follows:—£1,190 to defray excess expenditure on buildings, plant, and machinery, repayable in 17 years; £648 to defray excess expenditure on cables, services, and meters, repayable in 24 years; £1,500 in respect of new services, repayable in 15 years; £3,700 in respect of the proposed water-cooling plant (£300) and of the new mains (£3,400), repayable in 25 years. The Board request the Council to keep a separate account for each loan in future, to apply the loans only for the specific purposes in respect of which they were sanctioned, and to pass a formal resolution to this effect.

HULL.—Tenders are invited by July 29th for cables. Particulars from and tenders to the City Electrical Engineer.

LONDON: *Hammersmith.*—Application is to be made to the L.C.C. for a loan of £10,000 in connection with the electricity undertaking.

LUTON.—The Corporation require a 500-kw. generating set with condensing plant. Particulars from the Borough Electrical Engineer, to whom tenders by July 19th.

WALSALL.—The Electricity Joint Committee recommend an expenditure of £35,000 upon extensions at the electricity works and additional mains.

WOLVERHAMPTON.—An application is to be made for sanction to borrow £10,000 for mains.

Miscellaneous

BRADFORD.—Eight automatic point controllers are required by the Corporation. Particulars from Town Clerk, and tenders to Tramways Manager by July 30th.

HELLINGLEY (SUSSEX).—A storage battery is required for the Asylum. Particulars from the Resident Engineer, and tenders by July 20th.

HULL.—Tenders are invited by July 28th for electric fittings at the new Public Hall. Particulars from the City Architect, and tenders to the Chairman of the Property Committee.

ITALY.—The Rome Municipality invite tenders for the supply of rails, Phœnix type, for 20 km. of tramways.

LONDON: *London County Council.*—The Highways Committee recommend that the second section of the central car repairing depôt at Woolwich be proceeded with. The estimates include a sum of £1,500 for electric wiring, and £1,100 in respect of cables for power purposes.

SPAIN.—The Dirección-General de Obras Publicas, Madrid, says the *Board of Trade Journal*, invites tenders for a concession for the construction and working of a system of electric tramways in Barcelona. Tenders, accompanied by a deposit of £1,450, by August 27th. An application respecting this concession has already been submitted by the Compañia General de Tranvías, who have certain preferential rights in the competition.

SWITZERLAND.—Mr. J. Jenny, of Worblaufen, and Mr. F. Leder, of Berne, acting on behalf of a preliminary committee, says the *Board of Trade Journal*, have been granted an 80 years' concession for the construction and working of a single-track metre-gauge electric railway from Berne to Zollikofen, with a branch from the Tiefenau bridge to Worblaufen. Work must be begun within six months from the date of approval of the plans, and must be completed within 18 months. The total cost of the undertaking is estimated at 650,000 francs (£26,000).

WEST HAM.—Six double-deck tramcars, trucks, and equipments are required. Particulars from Tramway Manager and tenders by July 16th.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

E.—Domestic economy and metal-work centres on the "Millwall" site, Poplar (£4,053). Builders, F. & E. Davey, Ltd., Elmer Avenue, Southend-on-Sea.

St. Mary's Hospital, Plaistow (£14,337). Architect, A. Saxon Snell, 22 Southampton Buildings, Chancery Lane, W.C. Builders, F. & E. Davey, Ltd.

N.—School, Barnsbury Park, Islington (£9,541). Builders, Patman & Fotheringham, Ltd., Park Street, Islington.

Domestic economy centre, Nicholay Road, Islington, and alterations to other manual training centres in connection with Duncombe Road School (£1,391). Builders, J. Stewart, 174 West Green Road, Tottenham, N.

N.W.—School, Camden Street, St. Pancras (£12,531). Builders, McLaughlin & Harvey, Ltd., 13 Brecknock Road, N.W.

S.E.—School, Manor Lane, Lewisham (£16,235). Builders, F. & E. Davey, Ltd., Elmer Avenue, Southend-on-Sea.

Temperance hall, corner of High Street and Court Hill Road, Lewisham, for the Temperance Billiard Halls, Ltd.

Skating rink, Loampit Vale, also one in Burnt Ash Hill, Lee, Lewisham. Architect, A. Burr, 85 Gower Street, W.C.

S.W.—Extensions to bank, Wimbledon. Messrs. Rider & Son, c/o the London & County Banking Co., Ltd., Hill Road, Wimbledon.

School on the "Furzedown" site, Wandsworth (£32,767). Builders. J. & C. Bowyer, Ltd., Upper Norwood, S.E.

Blocks of offices in new street from Tothill Street to Prince's Street. Surveyors, Drivers, Jonas & Co., 23 Pall Mall, S.W.

PROVINCES.

DARWEN.—Alterations, Culvert School (£552). Architects, Sames & Green, Knott Street, Darwen.

—ECCLES.—The Health Committee of the Corporation invite tenders for the electric wiring and fitting of 12 houses in Corporation Road.

GLASGOW.—It is recommended that electric lighting should be installed in Queen Margaret College.

GLOUCESTER.—Additions, Council School. Architects, Medland and Pryer, 15 Clarence Street, Gloucester.

HOVE.—Extension at the Sanatorium (£5,477).—Builders, J. Parsons & Sons, 176 Church Road, Hove.

MAIDSTONE.—Class-rooms, Boys' Grammar School (£790). Surveyor, T. F. Bunting, Maidstone.

PLYMOUTH.—Alterations and additions to 14 Frankport Street (£1,294). Architects, Hine, Odgers & May, 23 Lockyer Street, Plymouth. Builder, J. B. Turpin.

St. Martin's Church, Weston Park Road. The Trustees.

REDHILL.—School (£6,620). Architects, T. R. & V. Hooper, Market Hall, Redhill.

ROTHERHAM.—School, Moorgate, for the Rotherham Education Committee.

Skating rink, Drummond Street, for the Sheffield and Provincial Skating Rink, Ltd.

SURBITON.—Isolation hospital. Architects, T. A. Lodge, c/o the Clerk, Surbiton District Council.

TORQUAY.—Palace of Varieties, Market Street. Architects, Bridgman & Bridgman, Bank Chambers Fleet Street, Torquay.

TENDERS RECEIVED AND ACCEPTED

DARLINGTON.—The tender of Messrs. W. E. Dove & Co. has been accepted for a motor-generator set, switchboard, &c.

DERBY.—An arrangement has been entered into with the Chloride Electrical Storage Co. for the renewal of the battery at the power house and its maintenance for ten years. It originally cost about £1,400. The Corporation to pay the sum of £100 down and £100 per annum for six years, and, in addition, £70 during each of the ten years, the company guaranteeing the battery to be in proper condition at the end of that period.

FAREHAM.—The Council have sealed tenders with the British Insulated & Helsby Cables, Ltd., and the Union Electric Co., Ltd., for the supply of cable and lamps respectively.

GLASGOW.—The following tender has been accepted in connection with the erection of a store, and the extension of the boiler house, &c., at the Port Dundas electricity works:—Messrs. Austin & Co., electric goods elevator, £215. For providing and erecting three motors for driving fans for cooling-towers at St. Andrew's Cross Station, the Electricity Committee have accepted an offer by the British Thomson-Houston Co., Ltd., amounting to £425 13s.

HESTON AND ISLEWORTH.—The tender of Messrs. Babcock & Wilcox, Ltd., at £310 has been accepted for the fixing of a chain-grate stoker.

KEYNSHAM.—The Council have accepted the tender of the Keynsham Electric Lighting Co. for public lighting at £260 15s.

LONDON: *Hammersmith.*—The Council has accepted the tender of the Western Electric Co. for the supply of 215 yards of 1·25 extra high-tension single cable and the purchase of 163 yards of 0·8 concentric extra high-tension cable to be replaced at £180 and £85 respectively.

Stepney.—The Council received the following tenders for the supply of carbons for two years:—Sloan Electrical Co., Ltd. (accepted), £1,091 13s. 10d.; Union Electric Co., Ltd., £1,122 16s. 8d.; Crompton & Co., Ltd., £1,144 6s. 9d.; General Electric Co., Ltd., £1,183 11s.; G. Braulik, £1,190 1s. 5d.; Siemens Bros. Dynamo Works, Ltd., £1,434 0s. 3d. The following tenders were received for two years' supply of meters:—Bastian Meter Co., Ltd., £281 5s.; Electrical Apparatus Co., Ltd., £402 10s.; Gillespie & Beales, £422 10s.; British Westinghouse Co., Ltd., £522 10s.; G. Braulik, £545; Electrical Co., Ltd., £577 10s.; Simplex Conduits, Ltd., £590 17s.; International Electric Co., £604; Reason Manufacturing Co., Ltd. (accepted), £671 10s.; Siemens Bros. Dynamo Works, Ltd., £712 15s.; British Thomson-Houston Co., Ltd., £761 10s.; Bat Meter Co., £765 3s.; Chamberlain & Hookham, Ltd., £878 10s.; General Electric Co., Ltd., £933 9s.; Ferranti, Ltd., £878 10s.

MANCHESTER.—Considerable discussion took place at the meeting of the City Council last week, concerning a proposal to accept a tender by Messrs. Siemens Bros. & Co. for the supply of service cables for twelve months at £1,998 10s. Messrs. Connolly Bros., who have had this order for many years, tendered at £2,033, and the Electricity Committee recommended the acceptance of Messrs. Siemens' tender in order to prevent any possibility of a "ring" being formed, if it became the policy to accept tenders only from Manchester firms. After a long discussion, a resolution to refer back the proposal was negatived, and Messrs. Siemens' tender was accepted.

ROTHERHAM.—The Council have accepted the tender of Felgate & Storey, Reading, for the installation of electricity at the High School for £225.

WARRINGTON.—The Council has accepted the following tenders for annual supplies:—Brush Electrical Engineering Co., transformers; Mawdsleys, Ltd., direct-current motors, ¼ h.p. to 5 h.p.; British Westinghouse Co., direct-current motors from 7½ h.p. to 20 h.p.; British Thomson-Houston Co., alternating-current motors.

WEST HARTLEPOOL.—The tender of Messrs. Cox-Walkers, Ltd., has been accepted for wiring the Henry Smith Schools at £192.

WOLVERHAMPTON.—The Council has accepted the tender of James Hodgkinson (Salford), Ltd., at £750, for a coal-conveying plant and coking stokers for the generating station.

COMPANIES' MEETINGS AND REPORTS

ELEKTRIZITATSWERKE LUZERN-ENGELBERG.—The accounts of this undertaking for the past year show a gross profit of 341,097 francs and a net profit of 195,781 francs. Dividends of 4½ per cent. on the preference shares, and 4 per cent. on the ordinary shares have been declared. A sum of 10,000 francs has been transferred to the reserve fund, and the balance, 630 francs, has been carried forward.

BERLINER ELEKTROMOBIL-DROSCHKEN (ELECTRIC CAB) AKT.-GES.—The revenue for the year 1908 amounted to approximately £104,000, and the expenses £79,000, leaving a net profit of approximately £25,000. Interests, writings off, &c., reduce this to a surplus of £550, which reduces the loss carried forward from the previous year to £12,100. The Company now owns 198 electric cabs, 28 private cars, and 5 repair vans, and in the past year the total number of miles run amounted to over 3,000,000.

KRAFTUBERTRAGUNGSWERKE RHEINFELDEN.—This German power company had in December, 1908, 19,103 kw. connected, which is 1,271 kw. more than at the end of the previous year. It it expected that the new water-power station at Wyhlen will be in operation before the end of this year. The total output in 1908 amounted to 102,500,000 units, of which 61,200,000 units were taken by two electrochemical firms, the Aluminium Ges. and the Griesheim-Elektron Ges., but the Company was obliged to purchase a further 28,000,000 units from other electricity works, in order to meet the demand. The capital of the Company was raised last year from 6,000,000 to 10,000,000 marks (approximately £500,000). The report for the past business year shows a net profit of 667,815 marks (approximately £33,400), which enables a dividend of 8 per cent. to be paid on the 6,000,000 marks, and a dividend of 5 per cent. on the 4,000,000 marks for the half year.

ELECTRIC & GENERAL INVESTMENT CO.—There was a gross profit of £11,565 on the trading for 1908. After meeting the interim dividends on the preference shares and providing for the final dividend to May 31st, 1909, there is a balance of £4,095, which has been carried to contingencies fund, raising this to £71,651. At the meeting last week, the report and accounts were adopted. Mr. J. B. Braithwaite, who presided, said the past year had been one of comparative stagnation, and there had not been the opportunity of employing the company's capital that there had been in former years. Nevertheless, they had been able to reduce their liabilities. In reply to a question as to a dividend on the ordinary shares, the chairman pointed out that the ordinary shareholders had already received a return of £4 16s. per cent. on every £1 share, and that, in the present position of the electrical industry, it was felt wiser to add the profit this year to contingency account. He thought, however, that there was every prospect of an early improvement in the present state of things, especially as the London Electric Supply Act had materially improved the position of the London supply companies.

EDMUNDSONS' ELECTRICITY CORPORATION.—The net profit for the year to March 31st, after payment of interest on the debenture and prior lien debenture stocks, amounts to £597. Adding to this amount the balance of £20,417 brought forward from the previous year, less the expenses of the issue of prior lien debenture stock, there remains the sum of £14,809, which the directors recommend should be carried forward to the next account. The dividends and interest received have increased by £2,871, the loss on working the Local Authorities' undertakings is reduced by £997, and the Urban Co.'s guarantee is less by £387.

VICTORIA FALLS & TRANSVAAL POWER CO.—The report for 1908 states that there is a surplus of £84,863, including the surplus from 1907 of £36,685. New issues of preference shares and debentures to the extent of £1,800,000 have been

Digitized by Google

made in connection with the formation of the Rand Mines Power Supply Co., Ltd., and its absorption into the Victoria Falls Co. As a remuneration for carrying through the difficult negotiations by which this amalgamation was carried out, the Board have voted a special sum of £7,500 to be divided between the Chairman and the Special Committee. By this absorption a competitor has been eliminated, as the Rand Co. had already entered into a contract with the Rand Mines, Ltd., for the supply of electrical energy. The original station at Brakpan, purchased from the Rand Central Electric Works, Ltd., is now mainly used as a reserve for the new 8,000-h.p. installation which was put to work in September. A contract to supply energy to the municipality of Johannesburg expired in June, 1908, and the plant released was at once employed for the power requirements of various mines. About half of the plant has been installed at the 16,000-h.p. station at Simmer Pan. The new transmission lines along the reef have been used since October. The construction of the necessary plant to fulfil the obligations of the Rand Power Supply Co., Ltd., in connection with fifteen mines, is now being put in hand. Mr. A. Hadley has been appointed Managing Director, with powers to be exercised in consultation with the Chairman, and owing to the increased work placed upon the Chairman in connection with the business of the company, the Board recommend that his remuneration should be fixed at £3,000 per annum. The Chairman and Managing Director will in future form an executive committee.

ANGLO-ARGENTINE TRAMSWAYS CO.—At an extraordinary general meeting last week, certain alterations in the Articles of Association were sanctioned. These have been rendered necessary by the reorganisation of the company consequent upon the fusion of the various tramway interests in the Argentine. The alterations deal principally with financial matters.

BRITISH ELECTRIC TRACTION CO.—Sir Charles Rivers Wilson presided over the annual general meeting on Thursday, when the report and accounts given in our issue for July 1st were adopted. He expressed the disappointment of the Board that the result of the heavy work during the last 13 years had not been more profitable in recent years. They had unfortunately fallen on evil times, having been subjected to unnatural competition and opposition by local authorities. The result had been a serious reduction of fares, representing a loss of something like £200,000 per annum. Their difficulties were now aggravated by the exceptional trade depression. They had been unable to make legislators realise the unnecessary obstacles and difficulties which were placed in the way of private trading concerns, and a general movement was springing up amongst those concerned that some steps must be taken to arouse public feeling in the matter. He hoped that with a revival of trade receipts would again increase, but he confessed his inability to predict when such a revival might be expected. For the current year, whilst they had been able to hold their own compared with 1908, there had been no marked improvement. A number of undertakings, however, were not yet fully developed, and as they had been able to arrest the constant pressure to reduce fares, there were hopes that the end of the year would show better results. With regard to the position of the Brush Co., a very small measure of tariff reform would make an enormous difference to the prosperity of the electrical industry generally. Mr. E. Garcke, who seconded the adoption of the report and accounts, said that no industry in the country laboured under such onerous legislative conditions as the electrical industry. The Electric Lighting Acts (Amendment) Bill had been referred to a Standing Committee instead of a Select Committee, so that parties like the B.E.T. could not appear and give evidence. One clause of the Bill gave local authorities power to compete in companies' areas without consent, whereas companies could not compete in municipal areas. There were other obnoxious clauses in the Bill, which, if passed, would still further depreciate the securities of electrical companies. It was impossible to read the Bill without feeling that it had been drafted with intent to prevent private enterprise from further engaging in the electrical industry; and it applied not only to future undertakings, but also to those already in existence. Mr. J. B. Braithwaite suggested that a new coin should be minted, of ten to the shilling, in order to increase the receipts, such a coin to be paid for the present penny stage. This proposition had already been considered by the Board, and they were advised that a special Act would not be required; it could be done by an Order in Council.

GENERAL ELECTRIC CO.—The report for the year ended March 31st last, states that the net trading profits and income from investments, &c., amount to £78,200, and, after deducting depreciation and debenture interest £26,987, there remains a balance of £51,213. The directors recommend a dividend on the ordinary shares of 5 per cent. for the year, transferring to reserve account £16,144, making a total reserve account of £136,488. Further ordinary shares to the number of 1,342 have been allotted during the period covered by the accounts to the directors and staff at par. Mr. H. Bevis tendered his resignation as director, which was accepted by the Board. The meeting is on the 19th inst.

NATIONAL TELEPHONE CO.—The report for the half-year to June 30th, 1909, states that the income amounted to £1,546,837 as compared with £1,452,569 for the corresponding period of 1908. The working expenses were £893,767, compared with £828,969. The net result for the half-year (after deducting the Post Office royalties amounting to £148,951) is a profit balance of £504,119, compared with £484,068. The rentals carried forward for unexpired terms of running contracts amount to £1,366,283, compared with £1,314,591. Out of the available balance of £379,850 the Board recommend the payment of a dividend at the rate of 6 per cent. per annum on the first and second preference shares, 5 per cent. per annum on the third preference shares, 6 per cent. per annum on the preferred stock, and 6 per cent. per annum on the deferred stock, less income tax in all cases. The Board also propose to transfer £150,000 to the reserve fund account, and to carry forward the balance of £11,100. The meeting is on the 22nd inst.

UNITED RIVER PLATE TELEPHONE CO.—The report for the year ended March 31st last, states that there is a profit of £89,233, to which must be added £4,904 brought forward from the previous year, making an available balance of £94,138. After applying £32,000 to reduction of special replacement account and £25,000 to reserve, the directors recommend a final dividend of 5 per cent. on the ordinary share capital, making a return of 8 per cent. for the year, free of income tax, that a sum of £2,000 be voted towards a staff provident fund, and that the balance of £5,138 be carried forward.

THE CITY & SOUTH LONDON RAILWAY CO.—The accounts for the half-year to June 30th, after providing for debenture interest and preference dividend, and the transfer of £1,500 to renewal fund, shows a balance out of which a dividend of 1¾ per cent. is recommended. A balance of £1,411 is carried forward. Last year the dividend on the ordinary shares was 1½ per cent.

BOMBAY ELECTRIC SUPPLY & TRAMWAYS CO.—At the annual general meeting on Tuesday the report and accounts given in our issue of July 1st were adopted. Sir Edward Sassoon, who presided, dealing with certain reports that had been circulated with regard to the financial stability of the company, stated that the past history of the undertaking was one of uninterrupted progress, its future prospects were very promising, and its financial position sound and free from any embarrassment. With regard to fares, the company had come to the conclusion that to carry passengers six miles for 1d. was unremunerative, and a proposal in this connection was to be placed before the municipality.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night was £59 5s. to £59 15s. (last week £60 to £60 10s.).

ELECTRIC RADIATORS AND COOKING DEVICES.—Messrs. Gillespie & Beales, of Amberley House, Norfolk Street, Strand, have been appointed selling agents for the Bastian electric heating and cooking devices. The radiators are of novel construction, and consist of quartz tubes or glowers, in which are mounted wire spirals, so arranged that the glowers and spirals within them are brought to a bright red heat within 15 seconds of the current being switched on. Cooking and heating stoves, water-boilers, irons, and other like devices are being rapidly perfected, and will shortly be placed on the market.

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—The business of Messrs. Mountain & Gibson, Ltd., is to be wound up voluntarily. Mr. H. H. Bowden, 77 King Street, Manchester, is liquidator. A meeting of creditors will be held at the Chartered Accountants' Hall, 60 Spring Gardens, Manchester, on Monday next at 3 p.m.

W. T. Harris, trading as W. T. Harris & Sons, electrical engineers, 460 and 464 Commercial Road, and 47 Emmanuel Street, Portsmouth, Hants, has been adjudicated bankrupt. The first meeting of creditors will be held on July 19th, at 3 p.m., at the Official Receiver's offices, High Street, Portsmouth, and the public examination on July 26th, at 11 a.m., at the Court House, St. Thomas Street, Portsmouth.

A meeting of the Chipping Norton Electric Light & Power Co. will be held at 1 West Street, Finsbury Circus, London, E.C., on August 11th, at 12 noon, to receive the Liquidator's account of the winding up.

The petition of Messrs. Harper Bros. & Co. for the compulsory winding up of the North-Western Electricity & Power Gas Co. was again before Mr. Justice Neville in the Chancery Division on Tuesday. It was stated, however, that negotiations are proceeding, and the motion was allowed to stand over.

In the Chancery Division of the High Court on Tuesday, Mr. Justice Neville allowed the petition of Messrs. Dick, Kerr & Co. for the compulsory winding up of the British Aluminium Co. to stand over. A further petition for the compulsory winding up of the company has been presented by Messrs. A. Schonfield & Co., 21 Hope Street, Glasgow, and will be heard by Mr. Justice Neville on Tuesday.

The Rex Electric & General Supplies, Ltd., is to be wound up voluntarily. Mr. W. Mackintosh Whyte, 11 Queen Victoria

Digitized by Google

Street, London, E.C., is liquidator. Particulars of claims by July 31st.

A general meeting of the Conduit & Insulation Co., Ltd., will be held at 23 Queen Victoria Street, London, on Wednesday, August 4th, at 2.30 p.m., to hear the liquidator's account of the winding up.

Mr. F. Geoghegan has ceased to act as Receiver and Manager of the Lowden Electric Co., Ltd.

A meeting of the Electric Taxicab Co. will be held at 7 Hertford Street, Mayfair, London, on August 19th, at 10.30 a.m., to receive the liquidator's account of the winding up.

VICKERS' ATHLETIC MEETING.—The second annual athletic meeting of the various Vickers, Sons & Maxim's works was held at the Vickers' Sports Club Ground, Carbrook, Sheffield, on Saturday afternoon, July 10th, teams from the following works taking part: Vickers, Sons & Maxim, Sheffield, Barrow-in-Furness, Erith, and London Office; the Wolseley Tool & Motor Car Co., Ltd., Birmingham; and the Electric & Ordnance Accessories Co., Ltd., Birmingham. Prizes to the total of £60 were offered, and in addition a 30-guinea Silver Challenge Cup was competed for, to be held for one year by the works whose representatives secured the highest number of points. The holders of this cup for the ensuing year are the Barrow works of Messrs. Vickers, Sons & Maxim, who scored a total of 17 points out of a possible 36. The winners of the cup last year were the Electric & Ordnance Accessories Co., Ltd., Birmingham.

AGENCY.—Messrs. W. T. Glover & Co., Ltd., of Trafford Park, Manchester, inform us that they have appointed Messrs. Haslam & Schontheil, of Western Mail Chambers, Cardiff, to represent them in South Wales, for the supply of electrical wires, cables, and accessories.

MISCELLANEOUS CITY NOTES

LONDON UNITED TRAMWAYS.—Although the earnings for the first six months of the year show a surplus sufficient to pay the dividend on the 5 per cent. cumulative preference shares at the reduced rate of 2½ per cent. per annum, the directors consider that until they can see their way to the resumption of the full dividend at the rate of 5 per cent. per annum, it will be better to postpone any distribution until the accounts for the whole year are before the Board. The registered office of the company has been removed to the company's principal office, High Road, Chiswick, London, W.

IMPERIAL TRAMWAYS CO.—The directors have announced that, owing to the 5 per cent. cumulative preference shares of the London United Tramways Co., Ltd., of which they held a large quantity, only being able to pay 2½ per cent. per annum for the first six months of the year, they regret that they are obliged to forego the distribution of the usual interim dividends, and await the results of the complete year.

HOBART ELECTRIC TRAMWAY CO.—A dividend of 5 per cent. free of tax has been declared.

FIFE TRAMWAY LIGHT & POWER CO.—Subscriptions have been invited during the week for 109,700 cumulative preference shares of £1 each. The list closed yesterday. This company is a consolidation of the Dunfermline & District Tramways Co., and the Fife Electric Power Co., and Messrs. Hawtayne & Zeden are acting as consulting engineers.

TELEGRAPH CONSTRUCTION & MAINTENANCE CO.—An interim dividend of 12s. per share, less tax, has been declared for the half-year to June 30th.

HASTINGS & DISTRICT TRAMWAYS CO.—The directors have announced that they are unable to pay any interim dividend on the preference shares.

NORTH MELBOURNE ELECTRIC TRAMWAYS CO.—The accounts for the year to September 30th, 1908, show a loss of £7,388, increasing the debit balance £16,285.

ORIENTAL TELEPHONE & ELECTRIC CO.—An issue of £50,000 four per cent. redeemable debenture stock at 86 per cent. is being made. The issue is to enable the Bengal Telephone Co. to meet the increasing demand for telephone communication.

MELBOURNE ELECTRIC SUPPLY CO.—Mr. David Finlayson has joined the Board.

INTERBOROUGH RAPID TRANSIT CO.—This company, which operates the Subway and Manhattan Elevated Railway systems in New York, is making an issue of $10,000,000 five per cent. 45-year gold mortgage bonds at the price of £214 19s. 3d. per $1,000 bond.

DIRECT UNITED STATES CABLE CO.—A final dividend of 4 per cent., with a bonus of 1s. per share free of income tax, is recommended, making 4¼ per cent. for the year to June 30th. The sum of £5,000 is placed to reserve, and £3,596 carried forward.

UNITED RIVER PLATE TELEPHONE CO.—A final dividend of 5 per cent. on the ordinary shares has been declared, making 8 per cent. for the year. The sum of £5,138 is carried forward.

APPOINTMENTS AND PERSONAL NOTES

The Sydney Municipality propose to advertise for a chief assistant electrical engineer, at a salary of £500 per annum, rising to £600 per annum by yearly increments of £50.

Mr. P. Storey, the Borough Electrical Engineer at Torquay, has been granted an honorarium of 100 guineas for his work in designing the plant to provide the tramway supply. The cheapest suggestion by Messrs. Kincaid, Waller & Manville, who were called in by the Corporation, for dealing with this supply, was at a cost of £16,000, but Mr. Storey has carried out the work at £13,599, which is actually £277 less than his own original estimate.

Mr. A. J. Brooks has been appointed Electrical Station Superintendent at the Avonbank power station of the Bristol Corporation at a salary of £175 per annum, rising to £200 after six months' service, and then to £250.

The Hammersmith Council received 220 applications for the position of fourth assistant engineer of the electricity undertaking. Mr. E. Taylor, of West Ham, was appointed.

Mr. W. L. Brown, chief assistant electrical engineer to the Morley Town Council, has resigned.

PARLIAMENTARY INTELLIGENCE

PROGRESS OF ELECTRICAL BILLS.—The Greenock Corporation Bill, the Oxford and District Tramways Bill, and the Edgware and Hampstead Railway Bill were read a second time in the House of Lords on Wednesday last week.

UNOPPOSED BILLS.—The following Bills, particulars of which have already been published in our columns, were passed by the Unopposed Committee of the House of Lords on Tuesday:—Oxford and District Tramways; North-East London Railway; Folkestone, Sandgate, and Hythe Tramways; Torquay and Paignton Tramways; Electric Lighting Provisional Order Confirmation Bill (No. 1); Tramways Provisional Order Confirmation Bill (No. 1)

NEW COMPANIES

FAIRBANKS, MORSE & CO.—Registered on June 14th, with a capital of £5,000 in £1 shares, to carry on the business of selling agents and salesmen of oil engines, motors, steam pumps, pumping, electrical and other plant and machinery. Private company. Manager, A. L. Cole, 87 Southwark Street.

CHARLESTOWN ELECTRIC LIGHT & POWER CO.—This private company was registered in Dublin on June 16th, with a capital of £1,500 in £1 shares.

ELECTRIC ORDNANCE CO.—Registered on June 24th, with a capital of £10,000 in 8,000 cumulative participating 10 per cent. preference shares of £1 each, and 40,000 ordinary shares of 1s. each, with objects as indicated by the title. Registered office, Ingram Court, Fenchurch Street, E.C.

ADNIL ELECTRIC CO.—Registered on June 29th, with a capital of £10,000 in £1 shares, to carry on the business of electricians, electrical and general engineers, ironmongers, makers of and dealers in electric tramcars, motor-cars, flying machines, aeroplanes, cycles, carriages, and other vehicles, manufacturers of and dealers in dynamos, motors, telephones, electroliers, arc, and other lamps, electric light fittings, &c. Private company. Registered office:—Adnil Building, Artillery Lane, E.C.

MEXICO STEEL & CHEMICAL CO.—This company has been formed, with a capital of 1,000,000 dollars, to manufacture steel and chemical products by the use of electrical power.

E. M. REDFERN.—Registered on July 5th, with a capital of £2,000 in £1 shares, to adopt an agreement with E. M. Redfern, and to carry on the business of electricians, electrical engineers, &c. Registered office: 9 Ethel Street, Birmingham.

GAVEN INRIG.—Registered on July 6th, with a capital of £2,000 in £20 shares, to acquire the business and assets of G. Inrig, of Great Eastern House, 20 Bishopsgate Street (Without), E.C., to develop and work the foreign patents granted to him for France, Belgium, Spain, Italy, Germany, Switzerland, Portugal, Canada, and U.S.A., and to carry on the business of electrical and general engineers, manufacturers of insulating material and rubber substitutes, &c.

L.C.C. TRAMWAYS AND COST OF STREET IMPROVEMENTS

A JOINT report by the Finance, Improvements, and Highways Committee of the London County Council upon the question of the allocation of the cost of street widenings, in relation to tramways, has been prepared. The question of charging any portion of the cost of improvements to the tramways account has only arisen of late years, viz., since 1899, which was the year when the Council first began to work its tramways. Prior to that date, the whole cost of street improvements was charged, without question, on the rates. From 1899 onwards, however, the allocation of the cost of each improvement has been considered on its merits, with the result that up to the year 1908, in 29 cases of important county improvements along tramway routes the Council decided to charge a portion, usually one-third, of the cost, to tramways account. The total number of improvements of all descriptions, part of the cost of which is to be charged to the tramways account, is 52. This method of dealing with the question, however, was felt to be somewhat haphazard, and on June 23rd, 1908, the Council passed a resolution referring to the three Committees mentioned above the duty of reporting upon the matter. These Committees appointed a sub-committee, who, after prolonged deliberations, arrived at certain conclusions. A joint meeting of the three committees was subsequently held, and the following recommendations are now made:—When the widening of a thoroughfare is entirely necessitated by the construction of a new tramway, or the doubling of an existing single line of tramway, and would not otherwise have been undertaken within five years from the time of such construction or doubling, it is recommended that the whole cost of the improvement shall be charged to the tramways account. Where an improvement is partly necessitated by the tramway, the balance of the cost shall be charged to the tramway accounts in certain proportions according to the benefit accruing to the general traffic and the tramway traffic. Other recommendations deal with various circumstances, in which street widenings and improvements may have to be carried out, the general effect of which would be that a larger proportion of the cost of street improvements will in future be charged to the tramway account. In all cases, however, the matter will be dealt with by a special committee consisting of nine members, three each from the Finance, Highways, and Improvements Committees, and before submitting any recommendation, the Committee is to obtain reports from the Comptroller, the Chief Engineer, the Valuer, and the Chief Officer of Tramways. This Committee will also decide whether certain of the recommendations should be retrospective.

A LARGE WATER POWER SCHEME IN NORTHERN ITALY

A GROUP of water-power stations, which together will form the largest electric power undertaking in the Alpine region, is now unders construction by the Società anonima per Imprese Elettriche Conti of Milan. Power is obtained from the Rivers Toce and Devero at three points in the vicinity respectively of Foppiano, Goglio, and Verampio, in the north of Italy. From these three generating stations energy is taken over high-pressure transmission lines to a transforming and distributing station at Novara, whence is fed an extensive network in the surrounding neighbourhood. The following details of the installations will give an idea of the nature and magnitude of the work, including that under construction and projected.

In the case of the power house in the neighbourhood of Foppianio on the Toce, the water is taken by a canal nearly a mile and three-quarters in length, and a delivery of about 46,000 gallons per minute with a fall of 1,115 feet is available. The generator station, at Rivasco, contains three main units of 3,500 h.p. each, in addition to the necessary exciting sets, &c. This station is practically complete, and was put to work during the third week in April. The construction of the station at Goglio, on the Devero, is in a very advanced state, and will be ready for the commencement of supply by the end of this year. The canal, which is a little less than a mile in length, and the pipe line will permit of the utilisation of 53,000 gallons per minute at a head of 1,740 ft. The station equipment, consisting of four main sets and two exciter sets, will aggregate 20,000 h.p.

With regard to the Verampio station, the company have already obtained a concession for a second deviation of the River Devero, and the designs for this third power house are all completed. This installation, the construction of which will be commenced next year, will utilise a fall of 1,840 ft. with a delivery of 53,000 gallons per minute, producing about 20,000 h.p. In order to equalise the flow of water available, which, coming originally from the Alpine snows, is reduced to less than half the normal in the winter, the company have been obliged to provide for a considerable amount of storage. This is being done by means of a dam about 43 ft. in height, which will increase the capacity of the lake of Codelago to an extent enabling over two thousand million gallons of water to be stored. The work on this dam has been commenced, and it is expected to be completed during next year.

The electrical power generated at these stations is transmitted at 50,000 volts by overhead lines to the main sub-station at Novara. The line from Foppiano to Novara is about 68 miles in length, and is supported on a double line of iron poles, each carrying six copper wires, and two intermediate sectionising points are provided at Gravellona and Borgomanero respectively, where switchgear is placed for cutting out sections of either line when required.

The sub-station at Novara is a large building, and contains provision for transforming the whole of the output of the power stations on the Toce and the Devero, and received at 50,000 volts down to 25,000 volts, at which pressure it is supplied to the distributing network. Adjoining the sub-station itself is an auxiliary steam station, in which plant to a capacity of 6,000 h.p. is already installed, but foundations are provided to accommodate extensions aggregating 18,000 h.p. From Novara a duplicate ring feeder of six wires passes through Mortara, Garlasco, and Vigevano, a total distance of about 50 miles, with distributing sub-stations at Mortara, Garlasco, Vigevano, Cerano, and Trecate. From these sub-stations radiate the distributing lines throughout the extensive district of the companies' activities, which comprises the greater part of the provinces of Novara, Alexandria, Pavia, and Milan. The detailed distribution of the energy supplied is in the hands of a group of six companies, whose combined capital amounts to about £200,000, of which a large portion is held by the Conti company. The total cost of the installations of the Toce and the Devero will be about £800,000, of which about £600,000 has been expended on the work that is already in hand.

In addition to the scheme which we have outlined above, the Conti Company have for some time been running the water-power station of Brembo. This station produces about 8,000 h.p., and, in conjunction with a steam station of about 4,000 h.p., and a like amount of power derived from the stations on the Rivers Adda and Adamello, supplies the rich and populous district of Brianza. Other installations worked by the same company include that of Boffalora Ticino, which supplies 6,000 h.p. to the Società Generale Italiana Edison di Elettricità di Milano, and ten important water-power undertakings at Cerano and Trecate, as well as the steam station at Magenta, which together produce 1,500 h.p. for distribution in the district between Trecate and Abbiategrasso.

The American Street and Interurban Railway Association.—We have received a copy of a circular letter, enclosing some particulars of this association, which is being addressed to officials and others interested in electric railways all over the world, inviting membership of all interested in electric railways, outside as well as inside the United States. The association has a number of active committees, who have done a good deal in the direction of collecting, recording, and discussing results of traction experiences, and in furthering the standardisation of equipment. A very large number of the railway companies in the United States are connected with the organisation, as well as individual members and associate members.

Finsbury Technical College Heat Laboratory.—Some interesting pieces of apparatus have recently been installed in this laboratory, which is under the direction of Mr. Charles R. Darling, Lecturer on Heat, and is open to both day and evening students. An electric furnace is used in many experiments, including one on the recalescence of steel. This furnace consists of a quartz tube, about 12 in. long, wound with nickel wire, and enclosed in an asbestos packed case. A temperature of 1,000° C. is obtained with an expenditure of about 500 watts Experiments with radiation pyrometers are also carried out with this furnace. Thermo-junction pyrometers consisting of iron-nickel couples enclosed in iron tubes are made and calibrated by the students, and experiments are also performed with a platinum resistance pyrometer. The laboratory is well equipped with reflecting galvanometers, and a four-meter wire potentiometer and bridge is employed. Another interesting experiment is an electrical test for the heat radiation from steam pipe and boiler lagging. A closed cylinder, covered with lagging, contains a large incandescent lamp in the centre, and thermo-couples are placed in the lagging at various depths (about every $\frac{1}{8}$ in.). The temperature gradient in the lagging is obtained in this manner, when the temperature has reached a constant value, and an accurate value of the surface temperature is found. The watts input to the lamp being known, the total radiation and the radiation per unit of area for any surface temperature are easily obtained.

CORRESPONDENCE

CHEAP UNITS.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—There are one or two points in connection with the discussion on the above subject to which, with your permission, I should like to make reference.

I was very glad that one or two engineers emphasise the desirability of avoiding all difficulties about the consumers' load factor by the method of making a fixed charge per annum per kw. of maximum demand, coupled with a low price per unit, and I would like particularly to call attention to the importance of taking account of the diversity factor in a systematic way in making the fixed charge. With your permission I shall give you my views as to how the diversity factor should be applied in reducing the fixed charge.

The effect of the diversity factor may be taken account of in two ways; (1) it may be expressed as the new ratio of the sum of the maximum demands of the various consumers (including the new consumer under consideration), to the new maximum demand at the station; or (2) it may be expressed as the *increment* of the sum of the existing maximum demands of the various consumers to the *increment* of the maximum demand at the station. The corresponding analogy in the matter of load factor would be that: (1) a consumer would only get the benefit due to the percentage improvement that he conferred upon the load factor of the station; or (2) he would get the whole benefit due to his own load factor. I contend that in the matter of diversity factor the consumer ought to be treated under the second method.

In the case which I cited at Manchester, the ratio obtained under the first method (assuming, for the sake of argument, that the existing maximum demand at the station was 20,000 kw., and that the sum of all the maximum demands of the power consumers amounted to, say, 40,000 kw.), would be

$$\frac{40{,}000+4000}{20{,}000} = 2{\cdot}2,$$

whereas in the second case it is :—

$$\frac{4000}{0} = \text{infinity}.$$

In other words, in the first case the consumer is only given a 10 per cent betterment upon what he would get if he came on at the time of peak, the same as the other consumers, whereas in the second case he would be *entirely* relieved of his capital, and other fixed charges, owing to his only coming on in the small hours of the morning, as in the case considered by me at Manchester.

If this principle be granted, and I cannot help feeling that it is the right one, then the allocation of the fixed charges becomes an easy matter, and it is only necessary to add a percentage of profit on to the true running cost to cover all cases. My point is that a consumer coming on in this way in the dead of night is just as profitable to the station if he is charged in the above manner as the ordinary consumer would be, and in some cases even more so. In the one case the station incurs a very big expenditure for the sake of getting a consumer; it has to pay heavy charges on account of that expenditure, and my contention is that there is no advantage to the municipality in the mere spending of greater capital sums of money and paying back the interest on these sums to the Government, but that the real advantage comes in the question of what is the *net profit* after all the other expenses have been met. It is this which goes to relieve the rates, or to reduce the cost of energy to future consumers. I do not therefore agree with the suggestion that has been made by some speakers, that a consumer with a maximum demand occurring between midnight and six a.m., should contribute something towards *capital* charges, but suggest that it is quite sufficient that he contributes towards *net profit* charges.

It also appears to me that in the desire to be scrupulously fair towards the old consumers, some of our friends are overshooting the mark, and are grossly unjust towards the new consumers. Really, we are hardly to expect that the old consumers started supporting the station from purely philanthropic motives, any more than we are to expect that the new consumers are going to be enormously more generous in *their* philanthropic motives. Anyway, the existing consumer has his remedies; he, too, can become a "restricted-hour" man if he chooses! Lastly, I am not at all sure that if the restricted hour system could be applied in the way I suggest, and carried up till reasonably late in the afternoon, a considerable amount of business might not be done in heating and cooking, as well as in power. Surely there can be no harm in offering the terms, if the station is properly protected against spurious peaks? There is at least the *chance* of capturing some new consumers, and that is worth something.

Yours faithfullly,

A. M. TAYLOR.

Avondale, Ashfield Road, King's Heath.
July 6th, 1909.

ELECTRIC LIGHTING ACTS (AMENDMENT) BILL.

To the Editor of ELECTRICAL ENGINEERING.

DEAR SIR,—May I direct the serious attention of electrical companies to the grave danger of allowing this Bill to pass in its present form. The Bill does not give effect—as might be inferred from the memorandum accompanying the Bill—to the recommendations of the Joint Committee of 1898, nor does it carry out the promises made by a former President of the Board of Trade. On the other hand, it imposes fresh conditions of a very onerous kind on electrical companies.

The effect of Clause 6 is to empower the Board of Trade to authorise a local authority to supply outside its area, and to compete with a company without the consent of such company, while a company can only be authorised to supply outside its area and compete with a local authority with the consent of such local authority.

Clause 13 relates to the audit of companies' accounts. Under this clause a company may be compelled to comply with the recommendations and requirements of the Board of Trade auditor in regard to matters affecting the interests of the authority empowered to purchase the undertaking. In view of the fact that many electric lighting companies have agreed with the local authorities on special terms of purchase, this clause is exceedingly dangerous to the interests of such company.

No one doubts the impartiality of the Board of Trade officials, but they cannot be expected to do more than fairly interpret the law, and if this Bill becomes law, many electric lighting companies are certain to suffer grievous injustice. It is safe to say that there is no precedent for this kind of legislation in the law affecting any other industry in this country.

Does anyone still doubt the urgent necessity of the electrical industry possessing some organisation which will protect its interest in these matters?

Yours faithfully,

E. GARCKE.

Electrical Federation Offices, Kingsway, W.C.,
July 12th, 1909.

ELECTROMETALLURGY AND ELECTRO-CHEMISTRY

AT the recent meeting of the American Electrochemical Society at Niagara, Prof. S. A. Tucker and Mr. E. G. Thomssen contributed a Paper on the "Deposition of Metallic Aluminium from Aqueous Solutions." From experiments with copper and other metals with rotating electrodes, it has been shown that the current density can be very greatly raised and yet a fine tough deposit be obtained. It was thought that by using a very high speed of rotation and a very high current density that it might be possible to deposit aluminium from aqueous solutions. With a speed of 20,000 r.p.m., and a pasty electrolyte of aluminium chloride, it was actually found possible to deposit aluminium. But on exposure to air it rapidly blackened. It was, however, possible to burnish it on a buffing lathe with rouge. The best temperature for the deposition was between 30° and 40° C.

The same authors read a paper on the "Electrolytic Deposition of Lead and Zinc." They have repeated the work of Classen in which he recommends the addition to the electrolyte of liquorice root or liquorice extract. The deposits obtained were in all cases very good, and adhered firmly to the cathode if it was perfectly clean at the start, and if the current density was not too high. Lead does not show a polished surface, but if the cathode is first polished then the zinc is obtained bright. When the plated articles are heated the lead adheres until it fuses, but the zinc becomes brittle and peels off. The fact of zinc peeling off on heating is objectionable, and is probably due to its containing carbon, which is deposited along with it owing to the liquorice, which is, of course, composed of carbon compounds. The authors have analysed the deposited metals and found in all cases the presence of carbon. The method does not appear to be so satisfactory as the older weakly acid bath, from which very good results can be obtained. Dr. H. E. Patten and Mr. W. R. Mott have deposited the metals sodium and strontium from saturated solutions of the iodides in acetone. They also deposited tin, antimony, cadmium, bismuth, and arsenic from solutions of their chlorides in acetone.

The New 3,000-kw. Set at the Glasgow Corporation Tramways Power Station.—In reference to the article on this set in our last issue, we are requested to state that, in accordance with the existing arrangements between Messrs. Richardsons, Westgarth & Co., Ltd., and Messrs. Brown, Boveri & Co., Ltd., the turbine part of this set was built according to the latter firm's designs, and is, in fact, interchangeable with similar machines built at their different works by Messrs. Brown, Boveri & Co., who are the Continental licensees of Messrs. C. A. Parsons & Co.

CATALOGUES AND PAMPHLETS, &c., RECEIVED

[READERS APPLYING TO ANY OF THE UNDER-MENTIONED FIRMS FOR COPIES OF THE CATALOGUES OR PAMPHLETS REFERRED TO ARE REQUESTED TO MENTION "ELECTRICAL ENGINEERING."]

COPPER-CLAD STEEL WIRE.—A pamphlet from British Insulated & Helsby Cables, Ltd. (Prescot) deals with Monnot copper-clad steel wire. This is manufactured by a process which may be briefly described as welding a coating of copper to a steel ingot. The copper-clad ingot is rolled into a rod and then drawn to the desired size of wire by the usual methods. The permanence of the weld between the two metals is conclusively demonstrated by the fact, that the proportion of copper and steel existing in the original ingot remains practically constant throughout the drawing process, even to the finest sizes. Monnot copper-clad wire combines the advantages, both of copper and steel. As compared with hard drawn copper, it is of great tensile strength, and at the same time its electrical conductivity is considerably higher than that of steel. In addition, the value of this wire for constructional line work is considerably enhanced by its immunity from corrosion, and for the same size, copper-clad wire is lighter than pure copper wire, giving a greater length for any given unit of weight. A special grade is manufactured for electrical purposes with a conductivity of 40 per cent. of pure copper; this is suitable for the equipment of overhead lighting, tramway, power transmission, telephone and telegraph lines, and all cases where maximum conductivity with minimum diameter is not essential. In many instances where copper wire is used, a much larger size is employed than is necessary for conductivity in order to give the required tensile strength, and for many overhead lines copper-clad wire may be used with considerable advantage, as longer spans are permissible with a consequent saving in poles. This wire can also be advantageously used for small telephone, telegraph, and other underground cables whose cores do not possess the tensile strength necessary to withstand the straining to which a cable is subjected during the process of laying or drawing in. For example, it should be used in every telephone cable having four conductors or less.

ELECTROLYTIC BLEACHING.—A pamphlet from Messrs. Siemens Brothers & Co., Ltd. (Caxton House, Westminster), contains a reprint of an article in a chemical contemporary upon "Electrolytic Plant for the Preparation of Sodium Hypochlorite." A series of tanks with electrodes of platinum iridium wire net are used in the process described.

ELECTRIC LOCOMOTIVES.—A new pamphlet from Messrs. Siemens Brothers' Dynamo Works, Ltd. (Caxton House, Westminster), deals with electric locomotives, both for mining and surface use, and gives particulars of a large number of locomotives of Siemens' manufacture in use in various parts of the world, exemplifying all classes of driving, namely, continuous-current supplied from an overhead line or accumulators, and those supplied with three-phase, or single-phase current from an overhead line. The first part deals with mine locomotives, following which is a section devoted to freight, goods, and mineral railways. Particulars are here given of locomotives for outputs up to 640 h.p., and for three-phase current or continuous-current up to 2,000 volts, including data of the locomotives supplied to or under construction for the Consett Iron Co., Ltd., co. Durham, and for the Harton Coal Co., Ltd., of South Shields. The remaining sections deal with locomotives of various descriptions, suitable for speeds up to 130 miles per hour, for branch and main lines. The number of single-phase locomotives in this section is 39, having a total capacity of 24,830 h.p. The company inform us that on a certain large railway system, the adoption of electric shunting locomotives at a roadside station, where the shunting operations amounted to about 30 miles per day, a saving of one-third of the cost of shunting with steam locomotives was effected, all capital charges being taken into account.

SPEED INDICATORS AND COUNTERS.—Mr. Jens Orten-Böving (72 and 74 Victoria Street, S.W.), is issuing a catalogue of tachometers, tachographs, engine counters, &c. made under the patents of Dr. Horn. These instruments are widely used on the Continent, and their manufacture in this country is contemplated. Special attention is called to the hand tachometers, which are made in a variety of useful forms, and for which great reliability is claimed. Other patterns listed include vertical and horizontal belt-driven engine tachometers, special high-speed instruments for steam turbines, locomotive tachometers, tramcar speed indicators, and several varieties of tachographs, giving continuous records on a paper drum, among which is a special instrument for accurate testing work, and a pillar instrument designed for winding engines, rolling mills, &c. An electrical excess speed indicator is also included.

PUMPS, FANS, &c.—We have received a collection of leaflets from the Albany Engineering Co. (Ossory Road, S.E.), embracing a considerable range of pumping and ventilating plant. The company make a speciality of a patent rotary pump, with an arrangement of grooves in the rotor, which give an effective water seal. These are tested for belt and electrical driving, and in various forms for special purposes. A high lift centrifugal pump is also made. The company's fans are fitted with a special form of blade calculated to give great efficiency.

AERIAL CABLES AND WIRES.—One of the latest lists from British Insulated and Helsby Cables, Ltd. (Prescot) gives particulars of braided aerial cables and wires, with a special weatherproof covering, consisting of one, two, or three layers of braiding direct on the conductor, thoroughly impregnated with a preservative compound. These coverings are for protection, and not insulation, and do not dispense with porcelain or other insulators.

SINGLE-PHASE MOTORS.—Messrs. T. W. Broadbent, Ltd. (Victoria Electrical Works, Huddersfield), have sent us a leaflet calling attention to their latest designs of single-phase induction motors, which, with their improved type of phase-splitting starter, can be started, on the loose pulley, without exceeding full load current. We have also been given particulars of a considerable number of orders for continuous-current as well as three-phase plant and switchgear which the firm have in hand.

SWITCHGEAR, &c.—A number of items of interesting switchgear and controlling apparatus are included in a new collection of leaflets from Messrs. Cowans, Ltd. (4 Queen Victoria Street, E.C.). Among these may be noticed the Cowan-Still variable regulating transformer, useful for a variety of purposes, and various patterns of instrument transformers and step-up testing transformers for voltages up to 75,000 volts. Resistances and field regulating rheostats are dealt with, as well as a considerable range of quick break and other switches, circuit-breakers, fuses, &c., for continuous currents, much of which is in accordance with Admiralty requirements. The alternating-current switchgear includes oil switches, with and without automatic releases, and relays and transformers used in Andrew's patent inductive balance protective system. Other leaflets describe the Andrew's current direction indicator, referred to on page 619 of ELECTRICAL ENGINEERING of July 1st, and the Andrew's and Glass patent service joint box.

MOTOR-STARTING AND CONTROLLING APPARATUS.—Particulars of a large range of "Igranic" rheostats and other motor-controlling apparatus, made by the Adams Manufacturing Co., at their works at Bedford, are contained in a comprehensive list just issued. Lever type starters and multiple switch type starters are listed with or without various forms of release, slow-motion gear, &c., both separately and as parts of complete motor panels. Perhaps the most interesting feature is the long range of automatic starting equipments, embracing special gear for pump motors, air compressors, hydraulic accumulators, &c., up to large sizes. Full reversing starters are also included, and compound starting and speed-regulating rheostats, as well as separate shunt speed regulators. Other special starters include three arm starters for slip-ring induction motors, automatic solenoid switches for alternating currents, auto-transformer starters, &c., and special controlling equipments for organ blowing, goods lifts, passenger lifts, including a complete push-button system and printing presses.

CONTROLLERS.—A picture postcard from the Electric and Ordnance Accessories Co. (Birmingham) reminds us that the controller for the 100 h.p. motor which drives the "Flip-Flap" at the "White City" was supplied by that firm. A description of the system of control was given in ELECTRICAL ENGINEERING, Vol. IV., page 180 (July 30th, 1908).

MEASURING INSTRUMENTS.—Two new publications from Messrs. Siemens Brothers & Co., Ltd. (Caxton House, Westminster), contain reprints of illustrated descriptive articles on switchboard instruments and current transformers respectively.

STEAM VALVES.—A coloured wall-sheet from Messrs. Alexander Turnbull & Co., Ltd. (St. Mungo Works, Bishopbriggs, Glasgow), gives a coloured section showing details of the firm's "Excelsior" patent full-bore parallel slide-valve, in which a positive closing effect is obtained by forming the valve-block in halves, with oppositely-inclined planes sliding upon each other in dovetail grooves, thus introducing a wedge action.

ENGINEERING PLANT AND MANUFACTURES.—The announcement was made recently in our columns of the establishment in London of a branch of the Machinenfabrik Augsburg-Nürnberg A. G. (M. A. N.), and a copy of this firm's English edition of their general catalogue gives an idea of the scope of their operations. After some historical and descriptive notes of the three works of the company at Augsburg, Nuremburg, and Gustavsburg, together employing about 11,000 workmen and officials, an outline is given of the principal manufactures, commencing with various types of boilers, superheaters, mechanical stokers, and large steam engines, with copious illustrations. The company also manufacture steam turbines under the Zoelly patents. Even better known than the steam plant are the Nuremburg gas-producer plants and gas engines, the latter of which are extensively used in large sizes with blast furnace, coke oven, and producer gas. During the last 12 years the company have turned their attention to the manufacture of Diesil oil engines for both land and marine work. Water turbines are also manufactured extensively, and other products of the works include printing machinery, refrigerating plant, hydraulic and testing machinery, vacuum plant, cranes, traverses, &c., and rolling stock for tramways and railways, besides the construction of bridges, roofs, and steel structures generally, for which some 30,000 tons of steel are consumed annually.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published July 8th, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

10,680/08. **Safety Device for Electric Heating Apparatus.** British Prometheus Co., Ltd., G. Cooper, and F. C. Chester. A knife switch which tends to open by gravity or by the tension of a spring, is normally held closed by a strip of soft fusible metal with enlarged ends, which engage slotted holders on the heated bottom of the apparatus and the switch arm respectively. When the temperature of the apparatus rises above the softening point of the strip, the latter is broken, and the switch is released by the action of the spring or a weighted lever. Three claims, eight figures.

10,948/08. **Automatic Circuit-breaker for Tramway Systems.** M. G. Newbould. This is an automatic relay for cutting off the supply to any section of a tramway system in the event of the overhead wire breaking. The relay comprises a plunger attached to a switch arm at each end, and under ordinary conditions kept in a state of equilibrium with neither switch closed by the opposing action of two solenoids. Each solenoid is connected in series with a resistance between the extreme end of one of the two trolley wires and earth. Upon the breakage of a trolley wire, the current ceases through one of the coils, the plunger is drawn over by the other coil, and the lever upon that side closes the solenoid circuit of the circuit-breaker, causing the latter to cut off the supply to the broken wire. Three claims, four figures.

15,092/08. **Continuous-current Transformer.** Akt.-Ges. Brown, Boveri & Cie. In this transformer, there are two D.C. machines coupled together; the exciting windings of each machine are in series with the armature of the other machine, and the fields are at right angles. If a constant pressure is applied to one side of the combination, a constant current will be supplied from the other side. In a modified form of the invention, the excitation of the field system is effected by the armature currents; for a two-pole machine, four-pole pieces are provided, not connected by any yoke of magnetic material, but the adjacent poles of the two armatures are connected so that a flux flows parallel to the shaft. The fluxes produced by the two armatures are at right angles. Four claims, four figures.

15,541/08. **Insulator.** C. M. Graham. The glass or porcelain insulator itself is provided with an outer thread and a large internally threaded cavity into which is threaded a treated wood support. The latter is transfixed by the fixing bolt, which has a counter-sunk head and a nut for fixing to the cross-arm. An inverted cup shaped protector of any rigid material, such as hard, impregnated wood, is screwed over the top of the insulator. Before screwing together, all the parts are coated with paraffin wax, and the outer wooden protector is coated with boiling tar. Five claims, three figures.

16,126/08. **Motor Starting Switch.** E. Garside. The switch arm is pivoted at its lower end in a vertical position, and arranged so as to open by gravity when released. In the operation of pushing the arm towards the switch contacts, a moving bridge is slid up a row of vertically arranged contacts, and the series resistances gradually cut out. A dash-pot is provided to prevent too rapid movement. The armature of the no-voltage release coil is attached to the upper end of the switch arm, and so the switch is held closed so long as the coil is energised. The sliding bridge is engaged by a detent pivoted on the switch arm, and is released directly the switch is closed. If the switch is opened it cannot be closed again without first pulling it out so far that the sliding bridge is engaged by the detent and again pushed up the contacts. Two claims, two figures.

20,635/08. **Recording Instrument.** H. Bevis and J. W. Penicud. This is a device for recording successively on one chart and by the use of one measuring instrument, the pressures or currents in a number of different circuits. The pointer, which carried an inking attachment and is fixed to the moving element of the instrument, is, in its normal position, free to move, without touching the paper, which is driven past the pointer by clockwork. The instrument is connected by means of rotating switches to the various circuits in succession, and different resistances are inserted if the values to be measured are approximately the same, so as to space out the markings. While the instrument is connected to any one circuit, an electromagnet attachment depresses the pointer so as to mark the paper, after a certain interval has been allowed for the pointer to become steady. Four claims, three figures.

Opposition to Grant of Patents

461/08. **Support for Metal Filaments.** C. H. Stearn and C. F. Topham. The appeal against the decision of the Comptroller to refuse the grant of this patent as a result of opposition has been withdawn. Full particulars are given on page 650 of this issue.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad. Summaries of some of the more important of these patents will appear in our next issue.

Arc Lamps: British Thomson-Houston Co., and Pollock [Regulation of supply to large arc lamps] 23,070/08.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: Taylor [Transformation of electric power] 15,522/08.

Dynamos, Motors, and Transformers: Lancashire Dynamo & Motor Co., and McLeod [Rotors] 13,504/08; Hartenheim [Motor control] 13,520/08; Midgley and Vandervell [D.C. machines] 21,936/08 and 21,938/08; Vickers, Sons, & Maxim, Ltd., and Williamson [Electric driving of planing machines] 23,908/08; Storer [Armature windings] 3,831/09; British Thomson-Houston Co. (*General Electric Co., U.S.A.*) [Motor-generator sets] 5,119/09.

Electric Ignition: Payne [Sparking-plugs] 17,912/03; Hay [Switch for ignition gear] 6,105/09.

Electrometallurgy and Electrochemistry: Richmond [Batteries] 9,900/08; British Thomson-Houston Co. (*General Electric Co., U.S.A.*) [Aluminium electrolytic cells] 1,345/09; Feltes & Guilleaume-Lahmeyerwerke Akt.-Ges. [Sterilisation of water with azone] 6,013/09.

Instruments and Meters: Hardingham (*Hartmann & Braun Akt.-Ges.*) [Speed indicators of the resonance type] 13,243/08; British Thomson-Houston Co. and Martin [Meters] 13,788/08; Ashington Coal Co., and McKie [Leakage indicators and recorders] 17,161/08; Siemens Schuckertwerke Ges. [A.C. meters] 27,343/08; H. Aron Elektricitäts Zählerfabrik Ges. [Single-phase meters] 28,271/08.

Storage Batteries: Van Raden & Co., and Metz [Accumulators] 15,388/08

Switchgear, Fuses, and Fittings: Sunderland and Pillinger [Automatic transformer switches] 13,185/08; Venner, Griesbach, and Morris [Electromagnetic switch] 13,327/08; Cooper and Sharp [Power switchgear] 14,773/08; Gott [Regulating switch] 19,757/08; Snook [H.-T. rectifying switch] 23,489/08.

Telephony and Telegraphy: Tyer and Dobson [Telegraphy] 17,143/08; Murray [Multiplex telegraphic printer] 26,918/08.

Traction: Zohrab and Biggs [Signalling] 12,957/08; Baldwin [Magnetic brakes] 13,781/08 MacDonald [Points and switches] 15,829/08; Helsing [Rail-joints] 16,189/08.

Miscellaneous: Electric & Ordnance Accessories Co., and Jacobsen [Blades of centrifugal fans] 25,175/08; Rapid Magnetting Machine Co., Thompson, and Davies [Magnetic separators] 335/09; Fairless and Dixon [Electro-magnetic door locks] 4,863/09; Plato [Converting series of contacts to continuous contact] 6,646/09.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Langbein-Pfanhauser Werke Akt.-Ges. [Rapid electroplating] 14,091/09; Siemens & Halske Akt.-Ges. [Signalling installations] 14,213/09; Siemens Schuckertwerke Ges. [Non-interchangeable safety fuses] 14,622/09.

Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: J. E. Kingsbury (*Western Electric Co., U.S.A.*) [Flexible conductor for telephone plug-circuits] 6,818/02; E. A. Carolan (*General Electric Co., U.S.A.*) [Apparatus for coating paper with insulating oil] 6,499/03; F. Everhart and J. J. Dossert [Conduit-pipe joints] 7,011/04, and [Cable-joint casing] 7,012/04.

Dynamos, Motors, and Transformers: E. A. Carolan (*General Electric Co., U.S.A.*) [Transformer connections] 6,484/03, and [Variable speed polyphase induction motor] 6,491/03.

Electric Ignition: G. Lentschat [Electromagnetic gas valve] 7,299/98.

Electrometallurgy and Electrochemistry: R. A. Hadfield [Use of electrical pyrometer when hardening projectiles] 6,091/01.

Instruments and Meters: E. Weston [Dynamometer measuring instruments] 6,990/98; W. Phanhauser [Electrolytic meter and automatic switch] 6,936/04; J. T. Armstrong and A. Orling [Electro-capillary detector and recorder] 7,044/04.

Storage Batteries: J. Diamant [Protection of positive plates from effects of electrolysis, sulphuric and carbonic acids] 6,954/03.

Traction: E. W. Rice [Motor-operated controllers] 21,551/98; A. J. Boult (*J. D. Price* and *W. D. Council*) [Block signalling] 5,964/01

Miscellaneous: R. W. Boyd [Incandescent lamp radiator] 5,906/01.

"Electrical Engineering," although the Cheapest Electrical Paper (Price **1d.** *weekly), contains the Most Useful and Practical Articles, the Best Illustrations, and the Latest News. It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.*

SUMMARY

A DEMONSTRATION was given on Saturday of the working of the Suchostawer Patent surface contact system on a short experimental track. In this system the switches in the studs are held off by a heavy iron plunger, which is lifted by the car magnet. No springs are used, a long break is secured, and there is no continuous conduit to require ventilation. (Page 665.)

THE accounts of the London County Council tramways for the year to March 31st show a net profit of £107,570 after meeting capital charges. The whole of this has been added to renewals account, £18,785 being in respect of the amounts which ought to have been added to this account in past years. The total expenses were 6·74d. per car-mile, and the total receipts 11·81d. per car-mile. (Page 666.)

THE report and accounts of the Poplar electricity undertaking record increased load in all departments except public lighting, where there has been a slight decrease, due to the introduction of metal filament lamps. The costs per unit sold have also decreased, and are now 1·42d. per unit, or without capital charges, 0·799d. (Page 666.)

AT an inquest last week upon the death of two men who were killed by electric shock, it was elicited that the shock was obtained from an electric coal-cutter working at 550-volts three-phase. An abrasion in the insulation of the stator winding caused contact to be made with the frame of the machine, and although the trailing cable contained a fourth wire for earthing, the connection between this and the machine was defective. (Page 667.)

IN his annual report upon the working of the West Ham electricity undertaking, Mr. A. H. Seabrook, late Electrical Engineer and Manager, and now Consulting Engineer to the Corporation, points out that there has been an improvement of £8,522 during the year, the accounts now showing a net profit of £3,854, against a loss of £4,669 in 1907-8. Since 1905, when Mr. Seabrook took over the management, the output of the undertaking has been quadrupled, the load nearly trebled, the number of motors increased six-fold, and the horse-power of same twelve-fold. The works costs are 0·52d. per unit, and the total costs, including capital charges, 0·977d. per unit. (Page 668.)

AN account is given of the present position of the street lighting in the City of London. (Page 669.)

Digitized by Google

WE give the final arrangement officially agreed by the Board of Inland Revenue in regard to allowances for depreciation in electrical undertakings for the purpose of income-tax assessment. (Page 670.)

A SERIOUS fire occurred last week at the Dundee generating station, entailing a stoppage of supply for some hours, and damage, principally to cables, amounting to about £1,400. (Page 671.)

THE report of the German Physikalisch-Technische Reichsanstalt for 1908, of which we publish a short summary, records a considerable range of research and testing work of an electrical nature, including some interesting tests of metal filament lamps, some of which appear to show a better life at an angle than hanging vertically. (Page 671.)

THE Electric Lighting Acts (Amendment) Bill was considered and passed by Standing Committee C of the House of Commons on Tuesday. A large number of amendments were made, a noteworthy one being the rejection of the addition made by the House of Lords that municipalities may only undertake wiring, &c., through a contractor. (Page 672.)

OUR Correspondent sends us some interesting particulars of the arrangements made by the Southend-on-Sea Corporation for supply for temporary decorative lighting during the visit of the Fleet. The load on the station has been increased by between 300 and 400 kw. (Page 673.)

The accounts of the Carlisle Electricity Department show a net profit of £2,222 for the past year.—Mr. H. Richardson, the City Electrical Engineer at Dundee, has complained to his Committee that the new power station is ready for work, but that the City Architect, who has had in hand the circulating-water arrangements, has failed to complete this portion.—The Ilford tramway accounts show a loss of £1,431 for the past year.—There is a debit balance of £3,930 upon the Marylebone electricity accounts for 1908–9.—It is stated that the Victoria Falls Power Co. have been offered a bonus to expedite the power supply to certain mines.—The Electrical Engineer at Southampton recommends his Committee to take up a wiring scheme. (Page 673.)

TWO 1,000-kw. turbo-alternators and water-tube boilers are required at Keighley; a 500-kw. steam dynamo at Pontypridd; mains extensions have been decided upon at Darlington, Aston Manor, and Yarmouth, and an expenditure of £14,000 is proposed on new sub-stations at Southend. A private telephone installation for 100 lines is required at the Edmonton Infirmary. (Page 674.)

THE accounts of Messrs. Crompton & Co. for 1908 show a net profit of £10,051, against £31,320 for the previous year. At the annual meeting of the General Electric Co. Mr. G. Byng again urged a revision of our fiscal system as an aid to British manufacturers. It was stated at the annual meeting of the Victoria Falls Power Co. that the greatest difficulty was not to find consumers, but to connect them up quickly enough. (Page 676.)

RECENT Papers read before the Physical Society deal with the measurement of high frequencies, calorimetry, and magnetic testing. (Page 677.)

WE publish figures of some very moderate bills for the electric lighting of private houses at West Ham. (Page 677.)

AMONG the specifications published by the Patent Office on Thursday last was one by Leo Sunderland and G. C. Pullinger, for an automatic transformer switch, and a switch for remote control operation by a clock switch or otherwise, is protected by R. F. Venner, R. C. Griesbach, and D. K. Morris. A method of short-circuited rotor construction is described in a patent by the Lancashire Dynamo & Motor Co., and R. S. McLeod, and G. Cooper and F. C. Sharp have patented a switch which can be only held closed when a current above a certain value is passing. Other patents include a leakage-recording system for mines by the Ashington Coal Co., and a peculiar form of double-armature generator by A. W. Midgley and C. A. Vandervell. (Page 678.)

THE particulars which we are able to publish in another column of the fatal electrical accident at the Clifton Colliery should be carefully read both by the designer and user of electrically-driven coal-cutting machinery. The first point that arises is particularly one for the designer. A machine which has to work under conditions as severe as those which usually obtain at the coal face in a pit must clearly be very highly tried, and therefore it is of the first importance so to design the electrical parts as to admit of their easy inspection, cleaning, and overhaul. A second consideration, and one almost of equal importance, is the necessity of efficiently earthing coal-cutter frames; of the methods of effecting this the best we have yet seen is that described on page 528 of our issue of June 10th, in the course of a Paper read by Mr. R. Nelson, H.M. Electrical Inspector of Mines. Had a "gate-end" box of the "Fisher" type been in use at Clifton Colliery the accident would have been impossible. We notice that in the jury's opinion there had been an "oversight" of some kind. The whole circumstances of the case emphasises the desirability of employing men underground upon whose technical knowledge and skill reliance may be placed. We venture to think that wherever else that class of person vaguely referred to as "the handy man" may be relied upon, he is out of place in responsible charge of electrical apparatus in coal mines.

The Telephone System.—Replying to a question in the House of Commons last week, the Postmaster-General stated that he was in negotiation with the National Telephone Company with regard to an earlier purchase of their undertaking than 1911, but it was not an easy matter to settle. In reply to a memorial sent him by the Associated Chambers of Commerce of the United Kingdom, the Postmaster-General said it was not possible to alter the present system of charging for telephone service. No final settlement of the question could be arrived at until some experience of the results of the transfer had been obtained. Any Parliamentary inquiry at the present time would be premature.

Telegraph Traffic.—The Trinidad-Demerara cable is again working, but the cable between Assab and Perim, which gave out on the 8th inst., is still down; messages must still be sent *via* Malta-Halfa-Kassala. Telegraphic communication between Barranquilla and Bogota, Republic of Colombia, is down, and messages can only be accepted at sender's risk. The cable between Bissao and Bolama was down for a short while on the 15th inst., the trouble apparently being near shore. The cable from Cayenne to Salinas is now working. The Dakar-Conakry cable came out of hospital on the 18th inst. The Chinese Government notifies that the cable between Chefoo and Dalny, which is jointly owned by China and Japan, and is worked by the former country at Chefoo, will not be open to international correspondence, but that the date on which this takes place will be notified later.

Damages for Electric Shock on Tramcar.—The West Ham Corporation have appealed against the judgment awarding £500 damages to a passenger on one of their tramcars who was injured through receiving an electric shock by coming into contact with the trolley standard, which was "alive." The case which the Appeal Court had to deal with was whether the Corporation was legally entitled to limit its liability for accidents to £25, by exhibiting a notice in the cars to this effect, on account of passengers being carried below the maximum fares. The appeal Court now upheld the judgment for £500 damages against the Corporation on the ground that passengers were not offered the option of paying the maximum fare.

THE S. P. SURFACE CONTACT SYSTEM

A DEMONSTRATION was given on Saturday, on an experimental track at the works of the J.-L. Manufacturing Co. at Southall, of a new surface contact system of tramway traction, with which Mr. David Suchostawer and other engineers associated with him have been experimenting for some time past. The system, which is to be known as the S. P., or Simplex Surface Contact System, is being developed by the Suchostawer Patents Syndicate, Ltd., and possesses several features of interest distinguishing it from the attempts of other designers.

In common with all surface contact systems, the method of current collection is by means of a long contact piece, in this case flexible, under the car, which is attracted down to and makes contact with metal studs placed at intervals in the road between the metals; and each stud is provided with a switching mechanism which, when influenced by a magnet carried on the car, connects the stud-head with the live underground conductor only when the car is over it.

The distance apart of the studs is, of course, settled by the size of the car and the length of skate which it is convenient to carry. Fig. 1 gives a general idea

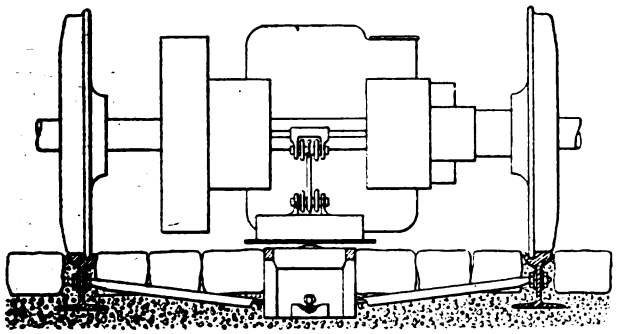

FIG. 1.—SECTION OF TRACK, SHOWING POSITION OF STUD AND COLLECTOR MAGNET.

of the relative positions of the stud-boxes, track, and car collector, and details of studs, &c., are shown in Fig. 2. Each stud is contained in a cast-iron box sunk in the ground and held to the track rails by tie-bars, which also act as earthing connections. The actual stud itself, with all its moving parts, is carried by an inner iron box, as shown in Fig. 2, which can

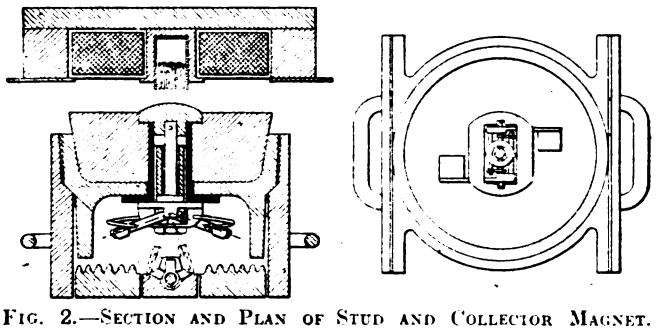

FIG. 2.—SECTION AND PLAN OF STUD AND COLLECTOR MAGNET.

be easily withdrawn after chipping out the pitch joint between the outer box and the paving blocks on either side. This pitch joint prevents excessive surface leakage from the stud to the earthed box. At the bottom of the box lies the live cable clamped into a special shaped contact piece of galvanised iron. The cable runs between the boxes in asphalte troughing or laid on any suitable solid system, and it is important to notice that there is no continuous underground pipe or conduit to require drainage or ventilation. The stud-boxes can be made watertight, and provision for draining them has not so far been found necessary in the experiments. On each side of the contact block on the cable in the box are corrugated tile insulators to increase the leakage surface as much as possible. It should be remarked here that even were the leakage from the conductor excessive across these insulators, the whole leakage current would go to earth through the cast-iron box, which acts as a guard ring, and the stud-head cannot possibly become live from this cause. Very little excavation is required for the stud-boxes, as their vertical overall dimension is only 9 in.

The stud-head itself is of iron or steel, sunk into the cover of the box, which can be of any material according to the paving. Under this is a brass stem connected to the switches, and round this stem fits loosely an iron sleeve or plunger, which normally bears on pins in the pivotted switch arms, and holds them up by its weight. When the car magnet passes, the iron sleeve or plunger is lifted and the switch arms fall one on each side of the contact block on the cable, thus making the stud live. There are no springs of any kind in the stud, and the switches are held off by gravity alone. The switch arms are provided with renewable carbon contacts, but under normal conditions the main current is not broken by them, so that they should last for an extended period. Flexible copper connections are provided as in a brush-holder, so that no current passes through the pivots. Attention should be particularly drawn to the long break obtainable, which is fully $1\frac{3}{4}$ in., and is ample to break currents due to leakage across the surface of the street without the necessity of condensers or other devices to extinquish the arc. Indeed, we ourselves saw a stud made to break eight amperes at 500 volts, which is considerably more than is likely to pass as leakage even under the worst conditions of mud, snow, or even salt. Another point that should be noticed is that there is purposely not a great deal of margin in the strength of the magnets, so that if there is a tendency for the plunger to stick, it will not lift at all, which is better than its being too forcibly drawn up and sticking in the "on" position. Again, the weight of the plunger and the suddenness of its descent when the magnet is removed are sufficient to ensure knocking off the switches even if they on their part show a tendency to stick. It is thus seen that several of the causes which might cause live studs have been either eliminated or, at any rate, reduced to a minimum.

The most important feature in the construction of the collector magnet on the car is the shortness of the magnetic circuit, which conduces to great economy in excitation. In fact, in the experimental equipment, which is provided with a 9-foot magnet weighing 1,400 lbs., the excitation required is only 180 watts. The arrangement is shown in Fig. 2. The magnet is virtually an elongated "pot" magnet, with the winding fully protected, and the return magnetic circuit is through the cast-iron stud-box and the outside of the magnet. The inner pole contains the flexible collector in a groove; being of magnetic material, it endeavours to complete the magnetic circuit, and descends to make contact with the stud. The collector is made up as a sort of brush of steel staples fixed in a strip of wire cloth, supported with adjustable tension from the ends only, and not held up with springs in any way. The collection is extremely steady, as could be seen by the lamps on the experimental car, which was run at speeds up to about 16 miles per hour. The groove within which is the collector is lined with insulating material, and the whole magnet is also insulated. The magnet is excited by a few accumulator cells when the current is off, but, when the car is running, the battery and the

Digitized by Google

magnet winding are in parallel in the main circuit, so that when the current is sufficient the drop across the magnet charges the cells. The usual arrangement of a trailing wire brush to detect live studs is provided, but otherwise the car equipment does not call for further remark.

In the experimental track at Southall the studs are placed alongside the track instead of between the rails, and the collector is supported on brackets at the side of the car. This was simply done for convenience, and does not affect the working of the system or the value of the experiment. The studs are exactly of the design that would be used in an ordinary roadway, except that the top of the boxes are of wood, and they are not covered in flush. Thus the reliable working of the studs in most respects has been demonstrated, but experience has not yet been gained under actual road conditions of mud, traffic, &c.

Both Mr. H. M. Sayers (Consulting Engineer to the Syndicate) and Mr. H. C. Furniss have reported favourably on the system, especially as regards the remote likelihood of trouble with live studs, and we must congratulate the inventor and those associated with him on their perseverance at a time when there is much prejudice against surface contact systems in general.

L.C.C. TRAMWAY ACCOUNTS, 1908-9

A REPORT has been prepared by the Highways Committee of the London County Council dealing with the financial results of the tramways during the year ended March 31, 1909.

The tramways system on March 31, 1909, extended over a total length of 127⅝ street miles, being 85⅝ miles of electric lines and 42 miles of horse lines. The capital expenditure on the undertaking amounted to £9,483,561 18s. 1d., of which £1,068,971 2s. 2d. represents expenditure during the year 1908-9.

The total debt repaid up to the same date amounted to £1,074,345 4s. 11d. out of revenue, and £282,519 12s. 8d. from the proceeds of sales of horses and old materials, &c. The debt outstanding on March 31, 1909, was £8,126,697 0s. 6d., or deducting £83,558 for the value of surplus land, £8,043,139 0s. 6d. The Council decided on June 23, 1908 (p. 1413), subject to the approval of his Majesty's Treasury, to repay the debt (estimated at about £960,000) on the capital which will be obsolete at March 31, 1914, owing to the electrification of horse tramways, within fifteen years from that date. The amount of obsolete capital, less proceeds of sales, on March 31, 1909, was £1,344,093 17s. 3d. Deducting the debt in respect of such capital repaid out of revenue, viz., £302,637 13s. 5d., the outstanding debt is £1,041,456 3s. 10d.

The total receipts from the undertaking during the year and the working expenses were as follows:

	Electric traction.	Horse traction.	Total.
	£ s. d.	£ s. d.	£ s. d.
Total receipts ...	1,572,251 8 7	275,199 1 7	1,847,450 10 2
Working expenses	896,286 4 7	305,402 0 2	1,201,688 4 9
Surplus on working	675,965 4 0	30,202 18 7 (deficiency)	645,762 5 5

After meeting capital charges, income-tax, &c., there is a net balance of £107,570 7s. 2d. Provision for renewals at the rate of two-thirds of a penny per car mile, amounting to £88,785, has been made, and the balance of £18,785 has also been transferred to the renewals fund towards deficiencies for past years. The "General Reserve Fund" now stands at £35,270.

The total operating expenses for electric traction was 6·74d. per car-mile run, as compared with 6·79d. per car-mile in 1907-8. The receipts were 11·81d. per car-mile, against 11·95d. in the previous year. The total number of passengers carried during the year was 412,913,841, and the number of car-miles run 39,119,472.

L.C.C. and Fires on Tube Railways.—The Fire Brigade Committee of the London County Council reports that the various tube railway companies in London have agreed to allow the chief officer of the L.C.C. Fire Brigade to make annual inspections of the fire appliances. There are seven tube railways in London, with 80 stations, and it is proposed to appoint an additional station officer to assist in carrying out the inspection. A proposal by the Fire Brigade Committee that all tube railways should have upon the platforms, and also on the street level, an illuminated sign which would show when the current to the live rail is cut off, is not considered reasonably practicable by the Board of Trade, and the Committee have decided to take no further action in the matter.

ACCOUNTS OF THE POPLAR ELECTRICITY SUPPLY UNDERTAKING

THE annual report of Mr. J. Horace Bowden, Chief Electrical Engineer and Manager to the Poplar Borough Council, records both an increase in the revenue and a decrease in the working costs per unit as compared with the previous year. The total income for the year ended March 31st, 1909, was £37,810, an increase of 7·08 per cent. over the figures for the previous year, and the working expenses £19,468 have only increased by 5·85 per cent. Of the gross profit, £18,342, interest and repayment of loans absorbed £14,662, leaving a balance of £3,680, which, with the deduction of certain minor charges, leaves a final net balance of £3,218, which is 20·5 per cent. higher than for the previous year. To this must be added £665 unappropriated balance from last year, giving a total available surplus of £3,882. Of this, £2,179 had to be devoted to certain purposes of a capital nature payable out of revenue, including mains, leaving an unappropriated balance of £1,703 to be carried forward to the next account, this being an increase of £1,038 over the corresponding figure for last year. The capital value of the undertaking now stands at £252,523.

An idea of the magnitude of the undertaking, and its progress during the year, can be gained from the following figures:—

	Year ended March 31, '08.	Year ended March 31, '09.
Units sold for public lighting	847,808	789,690
Units sold to private consumers ...	4,448,232	5,056,002
Total Units sold	**5,296,040**	**5,845,692**
Units used on works	413,906	428,965
Units expended in distribution, &c...	754,551	889,551
Total Units generated ...	**6,464,497**	**7,164,208**
Maximum supply demanded...	2,600 kw.	2,800 kw.

The increase in the output is made up as follows:—Private lighting, 6¾ per cent.; power, 15¾ per cent.; while public lighting has decreased 6⅞ per cent., due to increased use of metal filament lamps, making a net increase of 10½ per cent.

With regard to the change over from carbon to metal filament lamps, in the year prior to changing over, the cost for current supplied was £5,343, and last year £4,935, a saving of £408. The cost of lamp renewals was in the first instance £162, and in the second instance £497, an increase of £334, thus showing a net saving of £74, without taking into consideration the number of lamps converted from gas in the interval. By the change the Borough has gained in efficiency of street lighting from an initial 24 candle power per post and a steady diminution during use, to 50 candle power per post without any material reduction during life of lamps.

The following table analyses the cost per unit sold:—

	Pence.
Generating expenses:	
Coal	0·354
Water, stores, &c.	0·016
Wages	0·089
Repairs and maintenance	0·060
Total	**0·519**
Distributing expenses	0·054
Rent, rates, and taxes	0·100
Management	0·126
Total Costs (excluding capital charges)	**0·799**
Capital charges	0·621
Total (including capital charges)	**1·420**

The total, including capital charges, for last year was 1·429d., or, without capital charges 0·833d.

The Electrical Installation at the Worthing Theatre.—Judgment was given by Mr. Justice Bucknill on Wednesday of last week in the action by Mr. C. A. Seebold, lessee of the Worthing Theatre Royal, against Messrs. Page & Miles, to recover damages for alleged negligence in putting in an electric lighting installation worked by a suction gas plant. The defendants counter-claimed £25 for work done. A good deal of trouble had been experienced with explosions in the exhaust of the engines, which had damaged the exhaust silencers. After a long hearing, judgment was given in favour of the defendants, both on the claim and the counter-claim, with costs in both cases. Leave to appeal was refused.

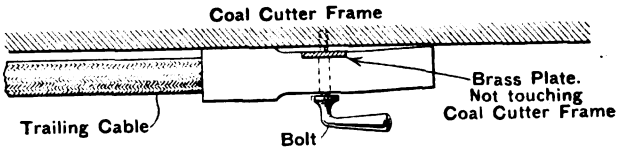
FATAL ACCIDENT IN A COAL MINE

AN inquest was held last week at Nottingham concerning the deaths of two men (Daniel I. Eyre, aged 29, and Samuel Higgs, aged 36) killed by electric shock on June 28th at the Clifton Colliery, Nottingham. There was no doubt as to the cause of the death, which was through the men touching the case of an electrical coal-cutter which had become charged. The coal-cutter was supplied with current at 550 volts three-phase (centre point not earthed), and the stator winding had come in contact with the case. Evidently there was sufficient earth on one of the other phases to give the fatal shocks. Artificial respiration was tried without success. There was a fourth wire in the trailing cable for earthing the frame of the machine, but the evidence showed that the connection between this and the machine was defective.

Mr. R. Nelson, the Electrical Inspector of Mines, and Mr. W. Walker, the District Inspector of Mines, were present at the inquest, and a memorandum by Mr. Nelson was handed in to the coroner.

At the colliery in question, they explained, electricity is used for driving coal cutters in the form of three-phase alternating current at 550 volts pressure. Though the Home Office Special Rules for Safety in Working Electricity in Coal Mines do not provide for the "earthing" of coal cutter frames, nevertheless at Clifton Colliery the machine frames were, very rightly, connected to earth by a special wire as a precautionary measure. Connection from the supply main to a coal cutter is made by what is known as a trailing cable—a flexible cable with three or more cores, usually kept in a coil and unwound as the coal cutter recedes from the supply control switch (called the gate-end switch), fixed at the end of the supply main. At Clifton Colliery this trailing cable had in fact four cores, the extra or fourth core being for the purpose of providing the earth connection above referred to for the machine frame.



The insulation of the wires joining the motor-winding had become worn through, probably by rubbing caused by vibration of the machine in working, and in this way live metal touched the inside of the machine casing; and as the earth connection was imperfect in spite of the fourth wire in the cable, the machine frame became charged to a dangerous pressure.

Taking the failure of the motor winding first, the memorandum pointed out that such a failure through abrasion is uncommon, and that there was therefore some excuse for the electrician-in-charge not having realised that a dangerous condition was gradually arising. Nevertheless, it was added, attention must be directed to the fact that had Electricity Special Rule 39 been closely observed, the accident might have been avoided. The wording of this rule is as follows:—

"The casings or inspection doors of all portable motors used underground, and the casings of their switches and other appliances shall at least once a week be opened by a competent person appointed by the manager, and the parts so disclosed shall be cleaned and examined before the coverings are replaced."

The object of the rule is to provide for periodical inspection of the windings of the motor where any danger exists of abrasion; and to provide that the interior shall be kept clean and free from oil. An inspection of this kind should have disclosed the fault before it became actually dangerous; but, the memorandum continued, it must also be said that the design of the motor casing in question is such as to make an inspection of the kind indicated difficult; and, more than this, there is a not inconsiderable risk of actually causing, in the act of replacing the casing, such damage to the motor winding as it is sought to avoid. The remedy lies in the direction of using only such machines as can conveniently be inspected without the danger last referred to, and no great practical difficulty exists in designing machines of this kind. The fault occurred in that part of the winding where three wires are led to the motor control switch. Special attention should therefore be given to the substantial support and fixing of these wires, so as to remove the possibility of abrasion at this part through vibration.

The second failure of the earth connection was due to an oversight in using a faulty piece of apparatus. The trailing cable above referred to was fitted with a wooden plug or "pommel" containing three sockets, which sockets were designed to fit over three prongs in the coal cutter motor terminal box. The earth wire, forming the fourth wire in the trailing cable, was fastened to a small brass plate on the side of the timber pommel, and connection between this brass plate and the machine frame (upon which the earthing of the latter depended) was made by a § in. diameter bolt, provided with a lever handle for screwing into the machine frame. In ordinary circumstances these arrangements should provide a sufficient earth, but in the present case an oversight upset them. The brass plate to which the trailing cable earth wire is attached was fixed on one side only of the pommel, and unfortunately, as regards the particular coal cutter with which it was being used, on the *wrong* side. The result was that the bolt was bearing on dry wood only, so that the earth wire was at least partially insulated from the machine frame. This fact would not necessarily have been fatal had the brass plate on the other side of the pommel been pressing against the coal cutter, but this again was not so. The brass plate stood very little, if anything, above the flat side of the pommel, but in any event the rounded end of the pommel, where the trailing cable entered it, served to keep the plate from contact with the machine frame. This point will be made clear by reference to the sketch below:—

It is understood that the coal cutters in the pit differ somewhat in design at their terminal boxes; and that the pommel in use at the time of the accident, though unsuitable for the coal cutter with which it was being used, was suitable for other coal cutters. Pommels had always been regarded as interchangeable, but they were not actually so, constituting an oversight on the part of the electrician-in-charge.

The memorandum concludes as follows:—

Where men without knowledge of electricity, and of what may be termed its properties, are placed in charge of the running of a motor, a special responsibility devolves upon those whose duty it is to provide for safety by maintaining the electrical apparatus in safe condition. In the present case, the precaution of earthing the coal cutter frame had been very rightly introduced, and it was this safeguard that failed. Had it been possible with the arrangements in use to make the earthing effective, and had the accident been due to some subsequent neglect on the part of the deceased men, it might have been possible to say that the accident was such as could hardly have been foreseen. But in the circumstances *it was not possible* to make the earthing effective, and therefore, however reluctantly, some degree of responsibility must be awarded the person responsible for the safe condition of the coal cutter on the day of the accident. Though that degree of responsibility cannot, in my opinion, be a very heavy one, in view of the fact that the failure to secure a good earth connection was due to the use of apparatus which, *though it apparently fulfilled its object*, was defective, the defect being one which only appeared upon close investigation.

To sum up the recommendations mentioned above so as to provide against such an accident in the future, they are four in number, namely:—

(1) Coal cutter motors should be of such design as to readily admit of the weekly inspection called for by Electricity Special Rule 39, without introducing the possibility of damage as in the case under notice.

(2) The wires inside the motor case forming the windings, and especially the end connections, should be substantially fixed and supported, so as to remove the possibility of the insulating material wearing away through abrasion caused by vibration.

(3) Machine "pommels" should be provided with a brass plate all over both sides to remove the possibility of bad connection between earth wire and machine frame.

(4) Some easy means (say a few cells and an electric bell) should be readily available *for occasionally testing the efficiency of such earth connections* as that between a cable pommel and a portable machine frame, so that after overhaul the latter may be left *beyond doubt* in safe working order.

The jury, after a few minutes' consideration, returned the following verdict:—

"The two men met their deaths by an accident caused by an oversight in the inspection of the machine, and by the pommel not being in working order to carry the escaped current away."

WEST HAM ELECTRICITY ACCOUNTS

MR. A. H. SEABROOK, the consulting electrical engineer to the West Ham Corporation, has issued a report upon the working of the electricity department for the year ended March 31st, 1909. In reporting a credit balance of £3,854 on the year's working, Mr. Seabrook points out that the improvement as compared with the previous year is £8,522, mainly due to the increased power business of four million to eight million units, and to the fact that the sales department has had a complete year under proper organisation, with successful results. The result of the reorganisation of the generating station has been that five and a half million units more have been generated than for the previous year, at an additional cost of only £700. The total expenditure for the year amounted to £39,123, as compared with £39,326 for the previous year, yet over four million units more have been sold. The total cost per unit was 0·52d., a reduction of nearly 33⅓ per cent. upon the previous year, and it is about the second lowest in the whole country.

On the question of assessment, Mr. Seabrook points out that the Corporation has nothing whatever to do with rating or assessments. These are fixed by an altogether independent and quite unsympathetic body, the Assessment Committee of the West Ham Guardians; but, continues the report, the fact that the undertaking has not been fully assessed at March 31st, 1909, does not alter the fact that an improvement in the results of working has been obtained to the extent of £8,500, as compared with the previous year.

As regards the revenue account, the most noticeable item is the reduction in the receipts from private lighting, which are only £22,784, as compared with £23,996 for the previous year. There is, however, an increase in revenue from power to the extent of nearly £8,200. Mr. Seabrook deals with the recent criticism of his power contracts as follows:—"This increase in power is practically all due to the contracts which were so violently condemned by opposing trade interests about a year ago at the Local Government Board inquiry. In spite of the fact that the amount of high-priced units, viz., lighting, has actually decreased, and the low-priced units, power, have increased enormously, there are still people who have the effrontery to say that the price at which we are supplying power is unremunerative, and figures are brought to prove that statement. Of course figures may be made to prove anything, but it appears to be a difficult matter to explain away the improvement in the department of £8,500, bearing in mind the class of supply from which the increased output has been obtained. I am perfectly certain that in view of the impossibility, owing to metal lamps, of rapily increasing the lighting business, that the position of this undertaking would be most serious if we had not had the benefit of a large increased business in the direction of power."

After expressing the opinion that the electric supply department of a corporation should take in hand not only the actual supply, but also the fitting up of works for electric driving, Mr. Seabrook deals with the sales department. This, he states, has made a profit of £500, after having charged up against it the whole of its own materials and labour, clerical work, canvasser's wages and commissions, supervision, printing, advertising, stationery, and 4 per cent. is charged also on all works carried out, to cover general establishment charges, &c. It is also pointed out that a great deal of the advertising carried out, although charged against it, does not benefit the sales department in particular, a considerable amount of advertising being done in the way of bringing the advantages of the borough before manufacturers, and inducing them to erect factories in the borough. Non-repayable work is also charged up against the sales department, mainly on the compulsory overhaul and putting in order of consumers' installations to induce them to re-use electricity which had been disused in the early days of high charges. The cost has been as much as £60 in one instance alone. This expense formerly came on the general undertaking, but is now carried by the sales department.

Attention is called to the fact that the net revenue account contains several special items amounting to £750, some of which are strictly capital expenditure, and others amounts written off, which do not refer to this particular year, and have therefore been charged to net revenue account. During the year there have been many other items, such as fixing new meters, &c., perfectly legitimate capital charges, but which have been charged to revenue. At recent Local Government Board inquiries a great deal has been heard about the over-capitalisation of the undertaking. To show that this is a most incorrect statement, Mr. Seabrook points out that the total capital expended per kilowatt of plant installed at the generating station is, at the time of writing, the lowest in the country. Taken on another basis, the capital expended per million units sold is also the lowest. Another point which has been made a great deal of is the fact that there is only a small reserve fund. From the statistics in the report it is seen that out of the total capital expended, £438,000, £93,000 has been repaid and in sinking fund. This repayment amounts to over 21 per cent. of the capital expended, and Mr. Seabrook thinks it is idle to argue in face of these figures, bearing in mind that the undertaking is only ten years old, that a substantial reserve fund is necessary. The report repudiates the suggestion that items have been charged to capital account which ought to have been charged to revenue; in fact, it is claimed that the reverse is the case. With regard to the allegation that the stores contains obsolete plant and apparatus, and is over-valued, it is stated that the total value of stock on a valuation would be found to be more than the book figure, owing to the very low prices at which the department has purchased materials—prices obtained in many cases by private negotiation, and lower than those the suppliers would put in a public tender.

Mr. Seabrook gives a comparison of the position of the undertaking at the end of the first completed year under his management, in March, 1905, and that at the end of March, 1909. From this it is seen that the output has been quadrupled, the load on the generating station nearly trebled, the number of motors increased by six times, and the horse-power of same by twelve times. The capital expenditure, on the other hand, has only increased by about one-third, and even now the full result of that one-third increased capital expenditure has not been felt. The Silvertown mains, for example, are not more than half-loaded, and a great deal more business can be taken on there, and also at the generating station, without increasing the capital charges appreciably.

There was a loss of £740 in 1905, as compared with a surplus of £3,853 in 1909, while at the same time the average charge to consumers was considerably less than half, being 1d. as against nearly 2½d. The charge for power is now only one-third of what it was in 1905; the total cost of production has been reduced from nearly 1¼d. to ½d., cost of management, &c., by two-thirds, cost of wages and repairs by half, and the cost of coal by half.

The total revenue for the year was £67,202, and the gross profit £33,365. Interest and special charges absorbed £14,904, and sinking fund a further £14,607. The details of the costs of generation, distribution, and establishment expense per unit are as follows:—Coal, 0·25d.; oil, stores, &c., 0·81d.; wages and repairs 0·17d.; rents, rates, taxes, management, 0·09d.; capital charges, 0·457d.; total 0·977d. The number of units sold was 15,522,065, the maximum demand being 6,100 kw.

In conclusion, Mr. Seabrook congratulates the Corporation upon having secured so able a man as Mr. H. H. Couzens as manager of the undertaking.

Turbo-alternator and Converter for Generating Continuous Current.—A somewhat unusual arrangement of generating plant which has been adopted by the Albert Lea Light and Power Co., of Minnesota, U.S.A., is described in the *Electrical World* (New York). The 300-kw. turbo-generator set is a low-voltage machine, and is connected to the alternating-current terminals of a 200-kw. rotary converter, which gives 250 volts direct-current at its commutator. The alternator will also supply step-up transformers giving 2,300-volt, three-phase current for general distribution. This will make a very flexible combination, and one which it is believed will operate more satisfactorily as regards direct-current output than would a direct-current generator of sufficiently high speed to be mounted on the turbine shaft. The turbo-generator when in operation can supply alternating current to the alternating-current distribution system, and also can feed into the direct-current distribution system through the medium of the rotary converter. When the turbo-generator is not running, direct current from the other generators in the plant will operate the rotary converter, which can feed alternating current through the step-up transformers into the alternating-current distribution system.

L.C.C. Tramway Extensions.—The Highways Committee have prepared a list of tramways for which it is recommended Parliamentary sanction should be sought next session. The total length is 23 miles 5 furlongs 9 chains, and the total estimated cost, exclusive of cars, car sheds, sub-stations, &c., is £417,000. The list of proposed tramways is as follows:—(1) Marble Arch to Harrow Road *via* Edgware Road. (2) Harrow Road to Cricklewood *via* Edgware Road, Maida Vale, High Road, Kilburn, and Shoot-up Hill. (3) Chalk Farm to Childs Hill *via* Chalk Farm Road, Adelaide Road, Upper Avenue Road, and Finchley Road. (4) Seven Sisters Road to Hanley Road *via* Fonthill Road to Tollington Park (double line), and single loop line *via* Evershot Road, Hanley Road, Regina Road, and Tollington Park. (5) Herne Hill Station to Brixton Hill *via* Dulwich Road and Water Lane. (6) Putney Bridge to Wandsworth, *via* High Street, Putney, Putney Bridge Road, and High Street, Wandsworth, to join the tramways in Garratt Lane. (7) Wood Lane to Harrow Road, *via* proposed new road between Wood Lane and Latimer Road, Silchester Road, Lancaster Road (double line), and a single line in Lancaster Road, St. Luke's Road, Cornwall Road, and Ledbury Road, and a single line in Ladbroke Grove, Cornwall Road, Powis Terrace, and Talbot Road, and a double line in part of Talbot Road and in Westbourne Park Road and Porchester Road and on Lord Hill's Bridge. (8) Extension of existing tramways in Tooley Street to near London Bridge. (9) Single diversion line along Archer Street and Bond Street, Vauxhall. (10) Additional double line of tramways on Dog Kennel Hill, Camberwell. (11) Diversion of a portion of one of the lines in Green Lanes.

STREET LIGHTING IN THE CITY OF LONDON

IN reference to our article on this subject in our last issue, the following account of the present position of the street lighting in the City of London (given as an appendix to the report referred to) will be found of interest. It is to be noted that the candle powers, consumptions, &c., of the gas lamps are not our own figures, but are simply quoted from the report.

ELECTRIC LIGHTING.

The total number of electric arc lamps in the City of London is 450. 380 open arc lamps and 20 flame lamps are fixed upon columns and brackets [in addition to the "experimental" lamps mentioned below]; the average distance between the open lamps is 126 ft., the average height of the lamps being about 18½ ft. The cost of each of the open lamps is £26 per annum, and of each flame lamp £17 10s.

In accordance with the Resolution of the Court of Common Council of July 25th, 1907, permitting the two electric lighting companies having statutory powers in the City to experiment with the newest form of electric lamps for street lighting in the thoroughfares of Holborn, Holborn Viaduct, Old Bailey (part of), the lamps being placed about 20 ft. from the ground, Cannon Street (between St. Paul's Churchyard and Dowgate Hill) at a height of 28 ft., and Farringdon Street at a height of 14 ft., the Charing Cross and Strand Electricity Supply Company proceeded with the lighting of their portion, viz., Cannon Street, by erecting 11 "Oliver" magazine flame arc lamps, centrally hung, and suspended over the roadway by wires attached to the buildings on either side. The lamps were put into lighting in November, 1907, and £17 10s. per lamp is the price paid for the experimental running. This is the price quoted by the company for a contract for not less than 250 of such lamps.

The City of London Electric Lighting Company also proceeded with the carrying out of their experiment by substituting 21 "Oliver" flame arcs for a similar number of the original "open" arcs, adapting the existing standards in Holborn, Holborn Viaduct, and part of Old Bailey, whilst in Farringdon Street 18 enclosed arcs of the "Reason" type were fitted up on special short columns in lieu of the 12 original "open" arc lamps and columns in that thoroughfare. The installation of this area was completed in November, 1907. The cost of the "Oliver" flame arcs in the Holborn area is £17 10s. each per annum, being equivalent to the charge for similar lamps in Cannon Street. The cost of the enclosed arcs in Farringdon Street is £12 10s. each per annum.

The "Oliver" flame arc lamps at Ludgate Circus and Ludgate Hill, put into lighting this year, are fixed at a height of 18·5 ft. above the roadway, as against 20·5 ft. with the experimental lamps of the same type at Holborn.

It is seen that the bulk of the electric lighting is by means of the old inefficient open arc lamps and lanterns unsuitable for diffusing the light to the best purpose, in continuance of the original system started in 1891. The "experiment" with the flame arc lamps was started in November, 1907, for a period of six months, and is being continued in periods of three months. In the meantime, a series of experiments are being made with gas lighting:

HIGH-PRESSURE INCANDESCENT GAS LIGHTING.

There are 119 high-pressure Keith gas lamps in the City thoroughfares, 42 upright single-burner lamps being fixed in the neighbourhood of Billingsgate on brackets. These lamps consume 10 cubic feet of gas per hour, and give an illuminating value of 300 candles each, at a cost of £7 5s. per lamp. They are from 60 ft. to 70 ft. apart on the diagonal, the height of burner from roadway being about 12 ft. They are fixed upon the house fronts, the roadway being about 50 ft. to 60 ft. wide. The lamps burn at 10 in. pressure from a special water-compressing plant placed in the adjacent pipe subway. The Corporation provided the compressing plant, services, lamp brackets and lanterns.

Forty-five upright two-burner lamps are fixed in Queen Victoria Street, each consuming about 20 cubic feet of gas per hour, and giving a light equal to 600 candles, the annual cost per lamp being about £13 2s. 3d. per annum. The lamps are fixed upon columns on the footpaths, about 100 ft. apart on the diagonal. The burners are 13 ft. 6 in. above the roadway, the street being about 70 ft. wide. The lamps burn at 10 in. pressure from a high-pressure trunk main direct from the gas-works, the Corporation providing the standards and lamps.

Seventeen high-pressure single-burner lamps (inverted mantles) have been fixed in Fleet Street and Chancery Lane upon brackets on the house fronts. These lamps each consume 25 cubic feet of gas per hour, and give a light of 1,500 candles, at an inclusive charge of £16 10s. per annum. They are supplied from a special 6 in. high-pressure main connected with a compressor house in the immediate neighbourhood, the pressure being 54 in. (water-gauge). These lamps are about 103 ft. apart on the diagonal, the height of the burners from the roadway being 13 ft. to 16 ft., the street being from 45 ft. to 70 ft. wide, the Gas Company providing the necessary compressing plant, mains, services, brackets and lanterns.

There are also several other "Keith" and "Sugg's" high-pressure lamps, fitted with upright 2, 3, 4 and 6 burners, on rests at the junction of roadways, of 1,000, 1,300, 2,000, and 3,000 candles, making 119 in all. In addition to the above the four City bridges are lighted with "Sugg's" high-pressure upright burner lamps, some 135 in number, giving 30 candles to the foot of gas; they are single-burner lamps with clusters on the centre of the bridges, and have been in lighting for about eight years, having been installed and maintained by the South Metropolitan Gas Company. The gas is compressed by separate gas and water-driven machinery on the bridges, except at Blackfriars, where the gas is taken direct from the high-pressure main of the Gas Light and Coke Company. The aggregate length of the four bridges is about one mile, the widths of the roadways varying from 45 ft. to 70 ft.

An experimental three-burner inverted "Keith" high-pressure lamp has been fixed in Fleet Street, consuming the same amount of gas as the single burner, and gives, it is stated, a like illumination, viz., 1,500, but with a better diffusion. Its improvement is that, if one mantle breaks, the remaining two will give a good light until a new mantle is put on, instead of the lamp being out. The annual cost of the lamp would be the same as the single burner.

In Queen Victoria Street, on the rest by Queen Street, an experimental four-burner "Keith" high-pressure inverted lamp has been fixed in one of the existing high-pressure lanterns in place of the two upright burners. The consumption of the four burners is the same as the upright burners, viz., 20 cubic feet per hour. It is claimed that the candle power is increased about 50 per cent., viz., 45 instead of 30 candles per cubic foot of gas, giving a total of 900 instead of 600 candles. The maintenance cost would be the same.

The "Keith" Lamp.—For the purpose of comparison, the "Keith" inverted lamp gives 60 candles per foot of gas consumed, against 51 to 53½ candles and 25 ft. consumption against 28 ft. of the "Graetzin," therefore:—"Keith" single burner, 25 ft. per hour at 60 candles per ft. as tested on photometer, equals 1,500 candles. "Graetzin" single burner, 28 ft. per hour at 51 to 53½ candles per ft., as claimed by Berlin figures, equals 1,400 to 1,500 candles.

A specimen of the newest form of "Graetzin" lamp with three burners has also been fixed in Fleet Street on the existing compressing plant, giving an illuminating value of about 4,400 to 4,555 candles with a consumption of about 84 cubic feet of gas per hour. [For description of this lamp see page 645 of our last issue.]

LOW-PRESSURE INCANDESCENT GAS LIGHTING.

The number of gas lamps, principally single burners of the upright type, at the end of the year 1908 was 2,640—each consuming 4¼ cubic feet of gas per hour—the illuminating power being 65 to 70 candles. Owing to the narrowness of the side streets the lamps are nearly all fixed on brackets about 60 ft. to 70 ft. apart at a height of about 12 ft. from roadway to burner, the annual cost of each lamp with gas at 2s. 5d. per 1,000 cubic feet being £3 10s. 2d. This cost includes maintenance of mantles, &c., but does not cover capital charges. A few 2, 3, and 5-burner lamps are fixed upon standards on the rests in the main roads and squares.

Low-pressure Inverted.—The only low-pressure inverted gas lamps in the City are a few "Carpenter" 1 and 2-burner lamps on trial, with a stated consumption of 4 and 8 cubic feet per hour, and 100 and 200 candle power respectively, being a claimed efficiency of 25 candles to the foot of gas consumed.

The price of gas for public lighting up to Midsummer was 2s. 5d. per 1,000 cubic feet, but this amount was then reduced by 1d., and a further reduction of 2d. per 1,000 cubic feet will be made as from January 1st, 1910, when the Gas Light and Coke Company will reduce the illuminating value of their gas from 16 to 14 candles, under their Bill now before Parliament, which has passed the third reading of the House of Commons. The effect of these reductions will be to decrease the annual cost of the newest type of high-pressure inverted gas lamp, as in Fleet Street, from £16 10s. to £15 2s. 6d., and all other gas lamps proportionately.

INCOME-TAX ASSESSMENT OF ELECTRICAL UNDERTAKINGS

THE question of the proper allowance for depreciation of electrical undertakings for the purpose of income-tax assessment has been under discussion with the Board of Inland Revenue for some time, the Tramways and Light Railways Association having taken it up on behalf of tramway undertakings, and the Incorporated Municipal Electrical Association on behalf of municipal electrical undertakings. In the July official circular of the Tramways and Light Railways Association, the final arrangements come to with the Board of Inland Revenue are published, and we give them below. It may be mentioned that this applies to both municipal and company undertakings. In the annual report of the Incorporated Municipal Electrical Association (ELECTRICAL ENGINEERING, July 1st, p. 610), it will be seen that the proposals, so far as electric supply undertakings are concerned, are dissented from. A point worthy of mention in this connection is that, whereas the tramway authorities seem to have been consulted on the matter and were successful in impressing their opinions on Mr. E. S. London, the Superintending Inspector of Taxes, managers of electric supply undertakings were not apparently made aware of the proposals until they were in draft form, and it was then stated that the matter had gone too far to be reopened.

TRAMWAY PERMANENT WAY.

1. The life of the permanent way is to be taken as 12, 14, or 16 years, according to the traffic thereon. The classification is to be based on the average car mileage per mile of track per annum of the financial year preceding the year of assessment, viz. :—

(1) Not exceeding 50,000 car miles per mile of track—16 years.
(2) Over 50,000 and not exceeding 75,000 car miles per mile of track—14 years.
(3) Over 75,000 and not exceeding 125,000 car miles per mile of track—12 years.
(4) Over 125,000 car miles per mile of track—special consideration.

2. Where there are special circumstances, such as exceptional gradients, and the compulsory use of wood-paving, &c., tending to show the car mileage does not fairly represent the wear and tear of the track, each such case is entitled to special consideration.

3. The cost of renewals, including setts or other paving, but excluding concrete foundations, should be taken at £4,400 per mile of single track until the general renewal of the track takes place.

4. No allowance should be made in computing the assessable profits in respect of any expenditure on repairs or maintenance of the permanent way, but the allowance for depreciation should be computed at such a sum per annum as will in the aggregate over the determined life of the permanent way be equal to the cost of renewal as above fixed plus the estimated repairs for that period :—

Cost of renewal per mile as above	£4,400
Add for example :—	
Estimated cost of repairs at £100 per mile per annum, for an undertaking with a life of 16 years	£1,600
	£6,000
Amount to be allowed per annum in lieu of depreciation, 1-16th	£375

5. The amount to be added in respect of ordinary repairs should be determined by taking the actual average expenditure as shown in the accounts of the undertaking for *the last three years*, or such period less than three years, as the undertaking has been in existence.

6. Repairs under this head should be understood to include renewals of special track work at junctions and cross-overs, which occur at frequent intervals.

7. Inasmuch as the expenditure on repairs is expected to increase as the track begins to wear, in which case the figure to be adopted under this head, which is to be based on past experience, will be unsatisfactory, the amount of such estimate should come up for revision at the end of every five years, and an adjustment should be made by increasing or diminishing the allowance as the circumstances require, having regard to the basis of calculation outlined above.

8. A strict account should be kept by the Corporation and the surveyor of the annual allowances, and of the actual expediture on repairs and renewals; and at the end of 10 or 15 years (*i.e.*, the second or third revision) or at such time as the general renewal of the track shall have taken place, the amount to be annually allowed should be reconsidered and increased or diminished for succeeding years as the ascertained facts shall show to be necessary, provided that under no circumstances shall the allowances for previous years be re-opened.

9. All expenditure on extensions and improvements should be excluded from the working expenses for income-tax purposes; and the necessary additional allowance for depreciation on the lines suggested above (*i.e.*, mileage) should be at once allowed on such expenditure, and added to the sum already allowable.

10. The allowance of £4,400 for renewal of permanent way mentioned above is intended to apply to the overhead trolley system. Special arrangements should be made, on the lines of the foregoing, in the case of the conduit, surface-contact, or other system. The number of such cases is very small. As the circumstances vary very considerably in each case, the amount to be allowed for renewals should in the first instance be arrived at by arrangement with the Chief Inspector of Taxes.

CABLES AND OVERHEAD EQUIPMENT.

11. *Cables.*—In addition to repairs, depreciation should be allowed at the rate of 3 per cent. per annum on the written-down value.

12. *Overhead Equipment* (*i.e., Trolley Wires and Connections*).—No depreciation should be allowed; all expenditure on maintenance and renewals should be charged as working expenses, as and when incurred.

CARS AND OTHER ROLLING STOCK.

13. Subject to the ensuing clause expenditure on maintenance and renewals should be treated as working expenses, and allowed in lieu of depreciation.

14. Depreciation, however, should be allowed in lieu of renewals where the circumstances justify such an allowance, provided that a strict account is kept of all renewals, and that if such renewals are charged to revenue account, they shall be shown separately in such account and added back in computing the assessable profits.

15. The allowance in such case should be 7 per cent. per annum on the written-down value.

16. In any case the annual expenditure on repairs is to be allowed as a deduction in computing the assessable profits.

GENERAL PLANT AND MACHINERY.

17. All other plant and machinery, including standards, brackets, and workshop tools, but excluding loose implements, office furniture, and small articles which require frequent renewal, should be bulked together and depreciation allowed thereon at the rate of 5 per cent. per annum on the written-down value, in addition to the cost of repairs.

GAS AND WATER UNDERTAKINGS.

18. No depreciation should be allowed in any circumstances in respect of any portion of these undertakings.

19. All expenditure on repairs and renewals, but excluding extensions and improvements, is to be charged and allowed as working expenses, as and when incurred.

20. Provided that whenever any exceptional expenditure on *bonâ fide* renewals is incurred, and full effect cannot be given to its deduction in that year owing to the profits or gains chargeable with income-tax in that year being less than the amount so expended, the balance of the said expenditure which has not been allowed may be carried forward and allowed in the following year or years, as is provided in the case of unallowed wear and tear by Section 26 (3) of the Finance Act, 1907.

ELECTRIC LIGHTING UNDERTAKINGS.

21. *Cables.*—In addition to repairs, allowance for depreciation may be granted at the rate of 3 per cent. per annum on the written-down value.

22. *Plant and Machinery.*—On all other plant, exclusive of loose tools, meters, and office furniture, depreciation may be allowed at the rate of 5 per cent. per annum on the written-down value, in addition to the cost of repairs.

23. *Conduits.*—No allowance should be made for depreciation; but annual expenditure on repairs and renewals may be allowed as working expenses, as and when incurred.

24. *Meters, Loose Tools, and Office Furniture.*—No allowance should be made for depreciation; but annual expenditure on repairs and renewals may be allowed as working expenses, as and when incurred.

GENERAL.

25. In all cases where depreciation allowances are granted, a strict account should be kept of the annual expenditure on renewals (and repairs in the case of tramway tracks), including replacements due to obsolescence, and of the amounts allowed for depreciation and obsolescence, whether under this arrangement, or under any arrangement made prior hereto, and a readjustment should be made for the future, if necessary, at the end of every five years, as detailed under Tramways (Permanent Way), subject, however, to the special provisions applicable to Tramways (Permanent Way).

26. Where depreciation allowances other than those for the permanent way of tramways are granted, renewals should be carefully distinguished, and, if charged against revenue, they should be notified to the surveyor, in order that they may be added back in arriving at the income-tax liability.

Digitized by Google

27. "Written-down value" means original prime cost, plus subsequent additions, less all allowances actually granted by the Revenue in respect of wear and tear.

28. These proposals are to take effect for the year 1908–9, and for years preceding in cases where claims of depreciation are at the present time awaiting settlement.

29. The computations necessary for any future adjustment should be duly made, agreed and recorded each year, whether the accounts for the particular year under review show any assessable income-tax liability or not.

30. Where, in any cases, allowances for depreciation have been made which are now to be discontinued, and they have not been exhausted by renewals already effected, the amount of such unexhausted allowances should be determined by agreement between the Surveyor and the Corporation or Company, and deducted from the expenditure on future renewals as and when they are effected.

31. All cases of dispute should be referred to the Board through the Chief Inspector of Taxes.

FIRE AT THE DUNDEE ELECTRICITY WORKS

A SOMEWHAT serious fire broke out at the Corporation Electricity Works in Dudhope Crescent Road, Dundee, on Wednesday of last week. The first indication of anything being wrong was the running away of a balancer owing to a heavy short on one side of the three-wire system, transferring the whole voltage to the other side. Immediately afterwards (about 4.45 p.m.) smoke was observed issuing through the floor immediately above the basement, and a hurried examination revealed the fact that the distribution cables had caught fire. The staff fire brigade was immediately called out, but so alarming did the situation get that it was thought advisable to call the City Fire Brigade. Within a few minutes of the outbreak the flames were shooting up until they reached the ceiling, a height of 40 ft., scorching the woodwork and breaking almost every pane of glass. Meanwhile the station had been completely shut down, and within half an hour the fire brigade had got the fire completely subdued.

An examination of the damage showed that the insulation of the cables in the basement had been completely burned away, leaving the bare copper wire, while two engines and dynamos, which are at present not in use and were in the basement, were also very severely damaged by fire and water. Two rotary converters and a large part of the sub-station switchgear have recently been erected, and were stationed close to where the fire originated, but fortunately no serious damage was done to them with the exception of a slight injury caused by the water.

The damage was such that nothing could be done in the way of supplying current again until the burned cables had been repaired. This arduous task was immediately started under the superintendence of Mr. H. Richardson, Borough Electrical Engineer, and by nine o'clock the work was so far accomplished as to permit of a supply of current for lighting being provided. After light had been supplied, efforts were directed towards giving a supply of current to the tramways. This was successfully accomplished a little after eleven o'clock, while at the same time light was supplied to the whole area of supply with the exception of Lochee, which is the furthest district from the station, and the tramcars were enabled to return to the depôts. The re-establishment of the supply entailed the putting in of some 63 cables and leads amounting to 3½ miles of conductors, and the short time in which this was accomplished reflects great credit on Mr. Richardson and his staff.

The amount of the damage, which is fully covered by insurance, is not yet fully known, but is estimated at about £1,400, not including loss of revenue to the tramway department to the extent of some £50. About 100 sq. ft. of the wooden flooring has been destroyed, but, of course, the main damage is to the cables in the basement, which are damaged over a length of about 60 ft. A certain amount of trouble was experienced on account of the sudden rise of the voltage on one side of the three-wire system, and burst lamps and blown fuses are reported. No damage to motors has been recorded.

Mr. Richardson is unable at present to state with certainty the cause of the fire, but various theories have been advanced. It has been suggested that it was caused by the presence of an explosive gas in the cable trench, although no report was heard to account for this.

It is also stated that children were seen playing with paraffin and matches near a manhole outside the station.

ELECTRICAL WORK AT THE PHYSIKALISCH-TECHNISCHE REICHSANSTALT IN 1908

THE Physikalisch-Technische Reichsanstalt at Charlottenburg continues to render valuable service to science and industry, and from the Annual Report of the work during 1908 it would appear that the test and research work have increased. The following particulars refer to the electrical part of the work. The usual routine tests on instruments and materials were carried out, the number being perhaps slightly greater than in the previous year.

As regards tests on electricity meters: in 5 continuous-current and 9 alternating-current meters of modern construction, the angular retardation of the armature by friction was determined as a function of its speed. It was found that while the friction of the bearings plus that of the air depends considerably on the number of revolutions, the friction of the counting mechanism plus that of the bearings are quite independent of the speed. The magnitude of the friction of the counting mechanism differs greatly in individual meters, and this obviously requires more or less careful manufacture. The transmission of the motion from the armature axis to the counting mechanism by a rack seems to be more favourable than worm-transmission.

Particulars of the changes in shellacked manganin coils due to varying humidity were published in 1908. The changes in question are so small in the German climate as only to be of importance for resistances equal to or greater than 100 ohms, and even then only for measurements of the highest precision. For resistance standards of 1,000 and 10,000 ohms, the changes during the summer of 1908 amounted to 5 parts in 100,000 only. By taking the precaution of keeping resistances in a hygrostat of 50 per cent. humidity, the constancy of all resistances up to a 100,000-ohm coil was secured. A comparison of the mercury standards with the manganin coils is in hand.

Various institutions (*e.g.*, the National Physical Laboratory, Teddington, and the National Bureau of Standards, Washington), have issued specifications for the setting up of standard cells, and detailed instructions for the preparation of the mercurous sulphate are given. It is directed that this salt shall not be washed with water, but with dilute sulphuric acid, or with a saturated solution of cadmium sulphate. The Reichsanstalt is of the opinion that the manner of washing the preparation is without influence on the result. It follows from this that the same e.m.f. results, whether the salt be hydrolysed or not.

The number of tests made on dry cells has increased in comparison with the previous year. In the last report the desirability was mentioned of continuing the intermittent discharging down to 0·8 volt. As, however, in the Testing Bureau of the Imperial Telegraphs the cells on an intermittently closed circuit was tested down to 0·7 volt, this limit has been adopted by the Reichsanstalt for similar tests. Numerous desires have, however, been expressed to test the dry cells on a continuously closed circuit down to 0·4 volt. In the test certificate, therefore, the total quantity of electricity yielded is given in two columns, viz., down to 0·7 volt, and from 0·7 to 0·4 volt, in order to render possible a comparison with the intermittently discharged cells. In the case of certain of the types of cell sent for test, a current of from 160 to 170 ampere-hours was obtained, with the cells placed on a continuously closed circuit having a resistance of 10 ohms. These cells weighed about 2 kg. The behaviour of the cells varied with the quality of the manganese dioxide used. In some types up to 120 ampere-hours were obtained with pressures above 0·7 volt.

The experiments on the quadrant electrometer with continuous-current voltage have been brought to a definite conclusion and the results published. The property of formed aluminium electrodes having a relatively large capacity has been utilised for the construction and test of a condenser of very large capacity. Ten aluminium plates, 10 by 16 by 0·1 cm. in two groups of five each formed the two electrodes, the capacity being 118 mfd. at a forming voltage of 100. On charging with alternating current, each of the condensers behaved as if it had only half the capacity of an electrode, as has already been shown by C. J. Zimmermann. The condensers were tested with various alternating-current pressures at 50

Digitized by Google

cycles, and with quick make and break. With the condensers permanently in circuit for a week with an average potential of 80 volts, no change in the condenser itself was noticeable. At pressures below 90 volts the energy losses scarcely increased at all with the duration of their remaining in circuit, but at higher pressures the losses increased considerably. At 250 volts the power factor increased to 0·3. If it is desired to obviate large energy losses and the deleterious heating of the condenser caused thereby, the load must be under 90 volts, and for higher pressures a number of condensers must be used in series.

A mercury vapour rectifier by the Westinghouse Co. was tested for behaviour and life, the latter being determined as 1,040 hours. In regard to the work done in the Magnetic Laboratory, mention may be made of a comparison of the methods of testing magnetic materials, and experiments on initial permeability.

The ordinary photometric tests were made during the year. The carbon filament glow lamps tested gave more favourable results as regards life than in the previous year. It is worthy of note to state that of a series of 24 of these lamps tested on a 234-volt A.C. circuit, 15 were still usable after having burned for 2,000 hours. In another series of 24 metal filament lamps (12 for 110 volts and 12 for 220 volts, half the number of each voltage were tested in a vertical position, the other 12 being at an angle of 45° to the vertical. They were run on alternating current. It was rather surprising that the latter batch showed a longer life than those hanging vertically. A number of tests were carried out on various forms of flicker photometer which could be used on a straight photometer bench, with a view to determining whether the use of the flicker photometer is to be advocated for test purposes. It was found, however, that this form of photometer offered to the skilled operator no advantage over the usual method of measurement as regards rapidity and certainty of adjustment.

ELECTRIC LIGHTING ACTS (AMENDMENT) BILL

Committee Stage Concluded: Municipal Wiring Permitted

STANDING Committee C of the House of Commons, to which the Electric Lighting Acts (Amendment) Bill was referred a few weeks ago, held its first sitting to consider the Bill on Thursday, but owing to the House of Commons having sat until 9 o'clock that morning, the necessary quorum of 20 members could not be obtained, and after waiting an hour the committee adjourned until Tuesday. Curiously enough, the House of Commons again sat all night on Monday, so that it was not until some time after the hour for meeting that 20 members out of the 80 comprising the committee could be mustered on Tuesday morning. Eventually 22 members arrived, but it was with some little difficulty that a quorum could be retained throughout the hour and three-quarters which sufficed for the committee to dispose of the whole Bill. Several members, in fact, who had handed in amendments, did not put in an appearance to move them.

The Bill, which was in charge of Mr. H. J. Tennant, Parliamentary Secretary to the Board of Trade, and has already passed the House of Lords, authorises the Board of Trade to issue provisional orders in many cases where it is at present necessary to proceed by private Bill, and generalises provisions usually inserted in local Acts dealing with electric supply. It also removes certain further difficulties which have been experienced in the working of the Electric Lighting Acts.

Clause 1 authorises the Board of Trade to grant provisional orders for the compulsory acquisition of land for the erection of generating stations, and to this no amendment was proposed in committee.

Clause 2 prohibits, after the passing of the Act, the acquisition of land by agreement for the erection of a generating station, except with the consent of the Board of Trade, without notice to owners and lessees within 300 yards. On the motion of Mr. A. H. Scott, the local authority is also to be notified. Another amendment limited the clause solely to generating stations, and this was accepted.

Clause 3 authorises the Board of Trade to grant provisional orders for the breaking up of streets in an area by a supply authority outside the area for the purposes of bulk supply.

Clause 4 provides for supply in bulk in cases where the Board of Trade does not think the undertaking too large to be dealt with by provisional order. An addition was made to the clause, on the motion of Mr. A. H. Scott, which provides that the consent of the local authority in whose area the supply is to be given shall be obtained for the breaking up of streets, but this must not be unreasonably withheld.

Clause 5 provides for the supply of electrical energy to railways, tramways, and canals, which may be used outside the district in which the supply is given. Amendments were proposed to include docks, and to make the consent of the neighbouring supply authority necessary, but these were rejected.

Clause 6 permits a supply authority to go outside its area to supply consumers in certain circumstances, for instance, when no supply is available. This was slightly amended in committee, in order to enable the Board of Trade to dispense with the consent of the outside local authority should this be unreasonably withheld.

Clause 7 gives power to a local authority to purchase the generating station of a company, when used solely for supplying the district, even though it be situated outside the district, but the clause will not be retrospective. It also allows one authority to transfer its right of purchase to another authority, where the company supplies the two districts. An amendment that this should be done without the consent of the companies in the case of those already existing was resisted by the Board of Trade and rejected by the committee.

Clause 8 authorises the creation of joint boards or committees for the purposes of electric supply.

Clause 9 relates to notices.

Clause 10 substitutes five years for seven as the ordinary period of revision of prices, and an application may be made by not less than 20 consumers.

Clause 11 makes an important alteration in regard to the procedure to be followed, by supply undertakers working under provisional orders granted after the passing of this Bill, in connecting up or changing consumers' meters. The undertaker is bound, under a penalty of 40s., to give a consumer 48 hours' notice before connecting or disconnecting a meter. The rules as to the certification of meters, hitherto practically a dead letter in most supply areas, are also modified, but in this case also the change will only apply in the case of provisional orders granted after the passing of this Bill. Unless otherwise agreed between the consumer and the undertaker, a "certified" meter must be used, as hitherto, but it is now made more clear what a "certified" meter is to mean. The Board of Trade allows certain limits of error for different classes of meters, and "approves" meters of certain construction and pattern, and the manner of fixing and connecting up. Meters are only to be considered to be "certified," however, if they are certified by an electrical inspector to be in conformity with the Board of Trade requirements in the first two respects, and the inspector may further be called in at any time by either the undertaker or the consumer, with the payment of a prescribed fee, to decide whether the method of fixing and connecting up is also in the manner approved by the Board of Trade. Although the modification in the meter clauses will only apply to new provisional orders, yet, as has been stated above, undertakers are already bound under the existing law to hire out to consumers meters each one of which has been individually certified by an electrical inspector, unless otherwise agreed between the undertaker and the consumer. Those supply authorities who do not use certified meters, therefore, will be well advised to have a special clause inserted in their consumers' contracts to meet the case.

Clause 12 prescribes that the accounts of all municipal electric supply undertakings shall be made up to March 31st. Other dates are permissible, however, where the circumstances demand.

Clause 13 in the original Bill gave the Board of Trade power to enforce an auditor's recommendation upon an electric supply company. Mr. Tennant, however, stated that this was strongly opposed by the companies, and he proposed to delete the original clause and substitute the following :—

"The Board of Trade shall from time to time make a return to Parliament giving such particulars as they may think proper with regard to the reports made by any auditors appointed by them to audit the accounts of any undertakers and any action taken on such reports by the Board and by the undertakers."

Clause 14 prevents any transfer of electric lighting powers without consent.

Clause 15 is the well-known Standby Clause.

Clause 16 as it stood authorised local authorities to undertake wiring, &c., but only through a contractor. It will be remembered that the restriction as to contractors did not appear in the original Bill, but was inserted on second reading in the House of Lords. On the motion of Mr. J. Parker, however, the words, "through a contractor but not otherwise," were deleted from the clause. This involved certain consequential amendments which were also made.

Clause 17 provides that a consumer must give the supply authority 24 hours' notice of his intention to quit his premises.

Clause 18 allows a supply authority to refuse to supply in cases of arrears of accounts.

Clause 19 professes to exempt agreements for the supply of electricity from stamp duty, but as a matter of fact it does not, as the Inland Revenue Commissioners rely upon another section of the Stamp Act, 1891, to that mentioned in the clause, in this connection. An amendment absolutely exempting electric supply agreements from stamp duty was ruled to be an amendment of the Stamp Act, and therefore out of order, and the original clause, useless though it is, remains in the Bill.

Clause 20 specifically states that the sections of the Electric Lighting Acts relating to "association" of undertakers do not prohibit "bulk" supply between them.

Clause 21 is for the protection of the Commissioner of Works, and gives him the right to inspect any generating station in relation to smoke nuisance. The new Horseferry Road station of the Westminster Electric Supply Corporation is exempted from the operation of the clause under an amendment accepted by the Board of Trade.

Digitized by Google

Clause 22 is for the protection of county councils, and a number of slight amendments were made in it.

Clause 23 is for the protection of gas and water undertakings.

A new clause was added, on the motion of Mr. Tennant, to the following effect :—

"Money borrowed under the Electric Lighting Acts shall not be reckoned as part of the total debt of a local authority for the purpose of any limitation on borrowing under the enactments relating to borrowing by the local authority."

Another new clause, proposed by Mr. Falconar and accepted by the Board of Trade, was to the effect that all electric apparatus which is the property of the supply authority, should remain the property of the undertaker, and not liable to distress either by landlord or mortgagee.

ILLUMINATIONS AT SOUTHEND

(FROM OUR OWN CORRESPONDENT.)

THERE is a large amount of decorative lighting in the streets of Southend and Westcliff to celebrate the visit of the Fleet to the Thames, and the following interesting information with regard to the special arrangements made by the Southend-on-Sea Corporation Electricity Department has been kindly given me in course of conversation with Mr. A. C. Johnson, Chief Assistant Engineer to the Department. A special rate of 1½d. per unit for decorative lighting has been fixed, and the necessary additional temporary connections on consumers' premises have been made free of charge. Special service connections were charged for. No meters are used for the temporary lighting, the consumption being estimated by the electricity department.

An idea of the amount of additional lighting that has been arranged is given by the fact that the maximum evening load on Monday and Tuesday was between 300 and 400 kw. greater than that of the previous week. The lighting system of the district is 2 × 230 volts three-wire, and, as it happens, the additional load is not equally divided between the two sides of the system. There is a small balancer in the station which normally deals with an out-of-balance current up to 150 amperes. On Monday night, however, the out-of-balance current was 390 amperes, and greater still on Tuesday night. To deal with this, an 80-kw. motor-generator, which is generally run as a connecting link between the 500-volt traction and the 460-volt lighting system, was run off the traction system and underexcited on the generator side, so as to deliver current to the lighting circuit at about 270 volts between the neutral and one of the outers. A temporary change-over switchboard was fitted up, so that either side of the system could be connected to the machine. Besides the ordinary balancer and the above machine, there was also a battery working on the system. Owing to the unusually high pressure (due to the out-of-balance of the system) the battery-booster has been working to boost up the battery voltage to that of the system. The additional load could not have been dealt with so easily had it not been that a new Belliss & Morcom-B.T.H. 500-kw. triple-expansion set was put in last October.

At the same time last year, namely, in October, a new Ledward & Beckett evaporative condenser was put in, and this and careful management have effected considerable economies in the running expenses. In the interval between April 1st and June 30th, 1908, the average running costs per unit generated (*i.e.*, coal, water, oil, and wages) amounted to 1·07d., but in the corresponding period this year the figure works out at 0·71d. per unit generated.

The traffic on the traction system has been very considerable over the week-end. As on Bank Holidays, all the twenty-five cars have been in service, and the load has often reached 400 kw. A special car, decorated to represent H.M.S. *Dreadnought*, is being run in the strets in the public service. In the decoration of this car 600 lamps have been used, and these give a very pretty effect in the evening.

LOCAL NOTES

BACUP: *Electric Tramways.*—It is expected that the new electric tramway system will be opened to the public to-morrow.

BODMIN: *Electric Supply.*—A private firm propose to erect an electricity works for general supply, and offer to light the streets and public buildings at £200 per annum.

BRISTOL: *Metal Filament Lamps.*—In presenting the accounts of the electricity department at the last meeting of the Corporation (ELECTRICAL ENGINEERING, July 15th, p. 654), Alderman G. Pearson gave a few instances of the decreases in private consumers' electric lighting bills in consequence of the adoption of metal filament lamps. These decreases ranged from 30 per cent. to 67 per cent. The latter was in the case of a small house with a small bill, which was reduced from £2 7s. 8d. to £1 1s. 5d.

CARLISLE: *Electricity Accounts.*—The accounts of the Carlisle electricity department for the year ended March 31st show a net profit of £2,222. In common with most of the towns in the north of England, the depression in trade generally made itself felt to a large extent, and the extended use of metal filament lamps caused some considerable reductions in the output to lighting consumers. Considerable alterations have been made in the plant and the working of the station, which have resulted in economies which have reduced the cost of production under every heading. The Corporation are extending the plant, and are now about to erect a complete set of auto-stokers and superheaters for all the boilers, a 300-kw. mixed pressure D.C. turbo set, together with surface condensing plant, and also a water-treating plant. This will give the extra plant capacity required at a low cost per kw., and increase the efficiency of the present plant considerably. The committee have very wisely decided to establish a reserve fund, and have allocated £1,000 of last year's profits to such an account.

DARWEN: *Electric Lighting Accounts.*—The accounts of the electricity undertaking for the year to March 31st show a gross profit of £3,922, and after meeting capital charges there is a net profit of £627.

DUNDEE: *New Electricity Works.*—The absence of condensing water, the arrangements in connection with which have been in the hands of the City Architect, was the cause of some discussion at the last meeting of the Corporation. Mr. Richardson, the City Electrical Engineer, reported that, so far as his department was concerned, the new station had been running since July 1st, according to the conditional promise given the committee. It had been discovered that one of the concrete piles of the condensing water tank had buckled, and it was proposed to drive in twelve timber piles along the face of the tank, and, in the opinion of the City Architect, it would be unsafe to attempt pumping from the tank while the divers were at work. Mr. Richardson concluded by saying that this was an instance of the nonsense or subterfuge which he had had to put up with in connection with this portion of the power-house, and which had made his enforced association with the City Architect so uncongenial and distasteful to him.

FAILSWORTH: *Street Lighting.*—The Council is making inquiries of the Manchester Corporation as to the probable cost of street lighting by electricity.

ILFORD: *Tramway Accounts.*—For the first year since the tramways were opened in 1903 the working during the past twelve months has resulted in a loss. There was an increase of expenditure of £1,020, caused by increased service to meet with motor-'bus competition, while on the other hand there was a decrease on receipts of £526. The loss is £1,431.

LONDON: *Bermondsey: Electricity Accounts.*—The accounts of the electricity undertaking for the year ended March 31st show that 2,781,583 units were sold, the income being £20,472. Both these figures are slightly below the estimates. The total expenditure was £18,443. After paying interest and sinking fund, the net profit amounted to £123, which is to be transferred to the reserve fund.

Chelsea: L.C.C. Tramways Bill.—The Council has decided to withdraw its opposition to the proposed tramway over Battersea Bridge.

Islington: Tramways.—The Works Committee recommend the Council to refuse to contribute towards the widening of New North, St. Paul's, and Canonbury Roads for tramway purposes.

Digitized by Google

Marylebone: Electricity Accounts.—The accounts of the electricity department for the year ending March 31st last shows that instead of the estimated deficit of £6,967, there is a debit balance of £3,930 only, and this notwithstanding £1,163 being spent in opposing Parliamentary Bills. 9,000,861 units were sold during the twelve months, the actual increase in sales being 369,750 units. The amount realised from sales to consumers, however, was £4,939 below the previous year's total, but this was due chiefly to reductions in price, and a good proportion of new business being in respect of the lower class prices of supply. Notwithstanding the increased quantity of current generated and sold, the total expenditure of revenue account was £6,475 below the estimate, and £10,207 less than the previous year. Generation expenses were ·62d. per unit sold, as against 0·73d. and 0·77d. in the two preceding years respectively. Distribution cost 0·16d., as against 0·25d. and 0·22d.; management cost, 0·22d., as against 0·24d. and 0·30d.; while rents, rates, and sundries was 0·19d., as against 0·19d. and 0·16d. in 1907–8 and 1906–7 respectively. The reduction in the generation account was largely due to judicious purchases of coal from time to time, and also to the bonus scheme, by which the men at the works share in the daily economies it has been possible to effect. The capital expenditure (excluding the purchase or goodwill price) works out at £59·5 per kw. installed, a lower figure than in the case of any London undertaking.

NAIRN: *Electric Lighting Order Revoked.*—The Board of Trade have revoked the electric lighting provisional Order granted to the Council in 1902.

NEWPORT (MON.): *Gas v. Electricity.*—At the last meeting of the Corporation, a Councillor mentioned a list of towns in which gas was used for street lighting, and urged that a trial of the two systems should be made in Newport. The Chairman of the Electricity Committee pointed out that in nearly all the towns referred to, the gas undertaking was owned by the Corporation, which was not the case in Newport. He claimed a saving of 7s. 6d. per lamp per annum over gas by the use of electricity.

Large Power Contract.—A sub-committee of the Electricity Committee has been appointed to select an engineer to report in regard to negotiations which have taken place between a large firm and the Borough Electrical Engineer for a supply of electrical energy in bulk. If the customer is secured an extension of the Corporation's plant involving an expenditure of about £70,000 will have to be made.

OPORTO: *Tramway Employees' Strike.*—The strike of the employees of the Electric Tramway Company came to an end on Sunday, terms having been arranged. The strike lasted for about a week.

PENZANCE: *Electric Lighting.*—The Board of Trade have threatened to revoke the Electric Lighting Order granted in 1904.

PORTSLADE: *Electricity Supply.*—The Brighton Corporation are to be allowed to supply Smith, Limited's. Flour Mills with electrical energy, on condition that the Council shall be allowed to take over the contract should it desire to do so in the future. It may be pointed out that the Portslade Council have not a Provisional Order yet.

RAND: *Power Supply.*—It is stated that the directors of the City Deep, Ltd., have offered a handsome bonus to the Victoria Falls and Transvaal Power Co., Ltd., if a supply of electric power to this mine can be given this month, instead of in October, as would be the case under the terms of the contract.

SHEFFIELD: *Effect of Metal Filament Lamps.*—In presenting the accounts of the Corporation Electricity Department at the meeting last week (ELECTRICAL ENGINEERING, July 15th), the Chairman of the Electricity Committee quoted the difference in the cost of lighting at the Town Hall, to show the saving effected by the use of metal filament lamps. For the March quarter of 1908, with carbon filament lamps, the cost was £176, whilst for the corresponding quarter this year it was only £121. For the June quarters the bills were £94 and £49 respectively.

SOUTHAMPTON: *Wiring Consumers' Premises.*—The Electrical Engineer has reminded the Electricity Sub-Committee that the period for which the Council deferred the question of obtaining powers to carry on free or assisted wiring has practically expired, and urges that every effort should be made to obtain the necessary powers in order to fully develop the undertaking.

TAUNTON: *Electricity Accounts.*—The accounts of the electricity department for the year to March 31st, show a gross profit of £4,138. After meeting capital charges, &c., there is a balance of £19 to be carried forward.

WARRINGTON: *Electricity Accounts.*—The accounts of the electricity undertaking for the year to March 31st show a gross revenue of £16,057, and working expenses of £9,318. After meeting capital charges there is a net profit of £942, which is £1,270 less than the surplus for the previous twelve months. The sale of lighting current was decreased by 32,250 units owing to the use of metal filament lamps, whilst the tramway department also consumed less electrical energy than in the previous year to the extent of 51,459 units. The coal cost was reduced by 18·65d., approximately half of which was due to increased efficiency in the new boiler plant, and the remainder to the lower price of coal. The average price received was 1·43d. per unit.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

ASTON MANOR.—Extensions of mains at an estimated cost of £112 are contemplated.

DARLINGTON.—Mains extensions have been decided upon at an estimated expenditure of £1,100.

DUBLIN.—Tenders are invited by July 26th for a year's supply of oils for the Pigeon House Fort electricity works of the Corporation.

KEIGHLEY.—Tenders are invited by August 7th, for two 1,000-kw. turbo-alternators and two water-tube boilers. Particulars from the Borough Electrical Engineer.

PONTYPRIDD.—Tenders are invited by July 27th, for a 500-kw. steam dynamo. Particulars from the Borough Electrical Engineer.

[illegible]HEND.—An expenditure of £14,000 is proposed on new sub-stations.

YARMOUTH.—A loan of £2,000 for further mains and house services is to be raised.

Miscellaneous

AUSTRALIA.—Tenders are invited by September 10th by the Deputy Postmaster-General at Sydney for ten switchboards, each for 100 metallic circuits. Forms, &c., may be obtained at the Commonwealth offices in London, 72 Victoria Street, S.W.

EDMONTON.—The Guardians invite tenders for the installation of a private telephone equipment at the Infirmary, consisting of a 100 lines, switchboard, &c. Particulars from the Architect, Mr. S. Hill, 106 Cannon Street, E.C., and tenders by July 28th.

LONDON: *London County Council.*—The Highways Committee recommend an expenditure of £18,920 for track work, cable ducts, and sub-stations plant in connection with the reconstruction of the Highgate Hill cable tramway for electric traction on the overhead system.

An expenditure of £5,350 is also recommended for the extension of the overhead trolley tramways from Beresford Square westwards along Beresford Street and High Street, Woolwich, to Nile Street.

Mile End.—The Guardians invite tenders for the supply of six Aron type wattmeters of 100-ampere capacity at 105 volts. Particulars from the Master of the Workhouse.

MANCHESTER.—Tenders are invited by the Tramways Committee for a supply of lighting cable. Particulars from the Tramways Manager, and tenders by July 27th.

ROTHERHAM.—An electrically driven air compressor is required by the Corporation. Particulars from the Borough Engineer and tenders by July 27th.

WALSALL:—The recommendation of the Electricity Joint Committee, reported in our last issue, to expend the sum of £30,000 upon extensions at the electricity works, and additional mains, has been adopted unanimously by the Council. A similar proposal last year was referred back, and it was in consequence that a joint committee was appointed to inquire into the matter.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

N.—Enlargement of Queen's Head Street School, Islington (£8,573). Builders, McLaughlin & Harvey, Ltd., 13 Brecknock Road.

S.W.—Alterations to National Schools, Mortlake. S.W. Builders, W. F. Blay, Ltd., 30A Spiltal Street, Dartford.

W.C.—New Theatre, Shaftesbury Avenue (1,840 places), W.C. Architect, B. Crewe, 75 Shaftesbury Avenue, W.C.

Alterations at Shaftesbury Theatre, Shaftesbury Avenue, W.C. T. F. Tugwell.

PROVINCES.

BARNET.—County School (£5,993). Builders, J. Parren & Son, Earith, Huntingdonshire.

BARNSTAPLE.—Tenders are invited by July 28th for the wiring of the Workhouse and Cottage Homes. Particulars from the Clerk, Boutport Street, Barnstaple.

HESTON AND ISLEWORTH.—School, Twickenham Road. H. J. Baker, Secretary, Heston and Isleworth Education Committee.

Digitized by Google

LOWESTOFT.—Extension of administrative block at Sanatorium (£1,786). Builder, A. G. Beckett, Lowestoft.

LUTON.—Public library, junction of George Street and Williamson Street (£8,873). S. F. L. Fox, surveyor, Town Hall, Luton.

MALVERN.—House (£3,306). Architect, T. W. Holds, Gt. Malvern.

NEWPORT.—Business premises, Clarence Place. A. Swash, c/o H. Duckham, Gaer, Pach.

RICHMOND (DUBLIN).—The adjourned Local Government Board inquiry into an application by the Guardians for a loan for electric lighting, was resumed yesterday. Owing to a re-arrangement of the proposed lighting circuits, the cost of the scheme is now put at £4,321 by Mr. H. T. Harris, the Consulting Engineer. The Corporation will supply the electrical energy.

SHEFFIELD.—Tenders are invited for the electric lighting of the Training College Hall for men. Particulars from the architects, Messrs. Gibbs & Flockton, 15 St. James' Row, Sheffield, and tenders to the Secretary, Education Office, Sheffield, by August 10th.

SOUTHAMPTON.—Addition to Royal South Hants and Southampton Hospital, Fanshawe Street. Builders, H. Stevens & Co., 126 Above Bar, Southampton.

Police Station and Coroner's Court, Payne's Road, Freemantle (£1,118). Builder, W. Buck, Jun., Southampton.

STOKE-UPON-TRENT.—Sunday school (S. Barnabas), Frederick Street. Rev. H. V. Stuart.

Skating rink, Wharf Street. Skating Rink Syndicate.

STRETFORD.—School, Seymour Grove, for the Education Committee.

WEST HAM.—The Education Committee are to obtain tenders for installing electric light throughout the Abbey School.

WHITEHAVEN.—Schools and caretaker's residence, Irish Street (£10,303). Architects, Oliver & Dodgshun, Carlisle.

TENDERS RECEIVED AND ACCEPTED

CARLISLE.—The following tenders have been accepted by the Council: Turbo-generator and condensing plant, Willans & Robinson, Ltd., £3,035; automatic stoker gear, Underfeed Stoker Co., Ltd., £1,076; super-heaters, Gordon & Co., £385.

COLWYN BAY.—The tender of Messrs. Chamberlain & Hookham, Ltd., has been accepted for ordinary and prepayment meters.

DUNDEE.—On the recommendation of the City Electrical Engineer, the tender of the Union Cable Co. has been accepted for the supply of cables. In justifying the acceptance of a foreign tender, Mr. Richardson said that the prices varied from 10 to 70 per cent. less than those of the English tenders. In this particular case, there would be a saving of £400 during the next eighteen months if the Union Co.'s tender was accepted. The English manufacturers alleged that the foreign makers were subsidised by their Goverument, while the foreigners declared that the English cable manufacturers were banded into a ring to keep up prices. A cable supplied by a foreign company had been working satisfactorily in Dundee for two years, and he left it to the committee to decide, the question being entirely one of price.

GENERAL POST OFFICE.—The following tenders have been accepted:—For supplying and laying feeder cables in connection with the new power station at Blackfriars, E.C., Western Electric Co.; supplying and installing telephone exchange equipment at Willesden, General Electric Co., Ltd.; hard-drawn copper wire, British Insulated & Helsby Cables, Ltd., and London Electric Wire Co., and Smiths, Ltd., John Wilkes, Sons, & Mappleback, Ltd.; copper wire, annealed, T. Bolton & Sons, Ltd.; bends, split and couplings Jones & Attwood; keyboard perforators, Gell Telegraphic Appliances Syndicate, Ltd.

LONDON: *London County Council.*—The following tenders have been received for the electric lighting of the New Cross fire station:—Tilley Bros., 53 Kingsland Road, Shoreditch, N.E. (*recommended*), £191; W. Leonard & Co., 4 Soho Street, Oxford Street, W., £197; G. E. Taylor & Co., 8 Bush Lane, E.C., £257; John Bryden & Sons, 90 Gloucester Road, Queen's Gate, S.W., £282. The chief engineer's estimate of the cost of the work was £295.

The tender of Messrs. W. Cory & Son, Ltd., for the supply of 130,000 tons of coal for the Greenwich generating station at 11s. per ton and a demurrage of 2d. per ton for each day after two days has been accepted.

Southwark.—The Council has accepted the tender of John Marsland & Sons, at £1,120, for the erection of a battery-room. The following tenders have been received for the erection and maintenance of a battery:—Hart Accumulator Co., Ltd., £394 16s.; Chloride Electrical Storage Co., Ltd., £390; Tudor Accumulator Co., Ltd., £351; D.P. Battery Co., Ltd., £280; Premier Accumulator Co., Ltd., £263; Electrical Power Storage Co., Ltd. (accepted), £247 per annum for fifteen years.

For the supply and fixing of four superheaters the tender of Messrs. Heenan & Froude has been accepted at £420.

For 110 yards of 0·3 by 0·3 by 0·125 paper insulated and lead-covered cable the following tenders were received:—British Insulated & Helsby Cables, Ltd., £56; Johnson & Phillips, Ltd., £56 15s.; Siemens Bros. & Co., Ltd., £56 12s.; Western Electric Co., Ltd. (accepted), £56.

Stoke Newington.—The Council has accepted the tender of the Reason Manufacturing Co., for demand-indicators, and of Messrs. Crompton & Co., at £150 for the provision and erection at Edwards Lane Station of a balancing machine.

Metropolitan Water Board.—The tender of Messrs. Glenfield & Kennedy, Ltd., at £450, for electrical water-level instruments and the installation of same, including the necessary line wiring, has been accepted.

MAIDENHEAD.—The tender of the Diesel Engine Co. has been accepted for a 150 kw. Diesel E.C.C. generating set.

SALFORD.—The Council has accepted the tender at £719 of Cleworth & Robinson, for the erection of a battery house and alterations to the existing buildings at the Frederick Road electricity works.

STRETFORD.—The Council has accepted the tender of E. Green & Sons, Ltd., for the replacement of the first cold end group of the economiser, consisting of 80 tubes and boxes, for £144 10s., and for the replacement of any other sections that may be required at £12 10s. each.

SWINTON.—The tender of Messrs. Callenders Cable & Construction Co., Ltd., for cables, has been accepted at £181.

MISCELLANEOUS CITY NOTES

CALCUTTA ELECTRIC SUPPLY CORPORATION.—An issue of 80,000 five per cent. cumulative preference shares of £5 each at par has been offered during the week.

MANAOS TRAMWAYS & LIGHT CO.—The lists closed on Tuesday for offers for £300,000 five per cent. first debentures in bonds of £100 each at £88 10s. per debenture.

CHELSEA ELECTRICITY SUPPLY CO.—An interim dividend of 4 per cent. per annum has been declared upon the ordinary shares for the June half-year.

CITY OF LONDON ELECTRIC LIGHTING CO.—An interim dividend of 5 per cent., less income tax, has been declared upon the ordinary shares for the past half-year.

METROPOLITAN RAILWAY CO.—A dividend upon the ordinary shares for the past half-year of 1 per cent. per annum has been declared, carrying forward £4,000.

VICKERS, SONS & MAXIM.—An interim dividend of 2½ per cent. (less tax) is announced upon the preferred five per cent. stock and the five per cent. preference shares, and 1s. per share (free of tax) on the ordinary shares.

MONTREAL LIGHT, HEAT & POWER CO.—A dividend of 1¾ per cent. has been declared for the quarter ending July 31st.

ST. JAMES & PALL MALL ELECTRIC LIGHTING CO.—An interim dividend of 10 per cent. upon the ordinary shares has been declared for the half-year to June 30th.

TELEGRAPH CONSTRUCTION & MAINTENANCE CO.—An interim dividend of 12s. per share is announced.

MISCELLANEOUS BUSINESS NOTES

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—The first meeting of creditors of the Uxbridge & District Electric Supply Co. will be held on July 29th, at 11.30 a.m., at 33 Carey-street, Lincoln's Inn, London, and will be followed at 12.30 p.m. by a meeting of contributors.

The petition for the winding up of Messrs. Mountain & Gibson, Ltd., which was adjourned on July 8th, will come before the Manchester Assize Court on July 26th. The Court will be asked to continue the voluntary winding up already decided upon.

A petition by Messrs. Pritchetts & Gold, Ltd., for the compulsory winding up of the London Electrobus Co., will be heard before Mr. Justice Neville, in the Chancery Division on July 27th.

The petition of Messrs. Dick, Kerr & Co. for the winding up of the British Aluminium Co. has been allowed to stand over until next term. The company state that they have an improving business, and that a scheme will be arranged for carrying on the business at a profit.

CHANGE OF ADDRESS.—Messrs. James E. Sayers & Caldwell inform us that their address in future will be at 190, and not 157 West George Street, Glasgow.

OUTING.—The Bryant Trading Syndicate, Ltd., held the annual outing of their "Metalite" lamp works staff on Saturday last, when about two hundred of the girls spent a thoroughly enjoyable day at Brighton. Sports were held during the morning, and some novel and appropriate competitions were introduced, such as the Metalite lamp and spoon race, filament counting race, "potato" race with Metalite lamps instead of potatoes.

LONDON OFFICE.—Messrs. A. & T. Burt, Ltd. (New Zealand), have opened an office in London at Eldon Street House, London, to execute the buying for New Zealand houses. The office is under the charge of Mr. Jas. A. Burt.

FIRE.—A slight outbreak of fire occurred at the works of the Morley Electrical Engineering Co., Bradford Road, Stanningley, Leeds, on Thursday.

ANNUAL HOLIDAYS.—The works and offices of the Electric & Ordnance Accessories Co., Ltd., will be closed on Friday, July 30th, at 6 p.m., and during the whole of the first week in August, re-opening on Monday, August 9th.

PARLIAMENTARY INTELLIGENCE

CENTRAL LONDON RAILWAY.—This Bill was before the Unopposed Committee of the House of Lords on Tuesday, and was sent forward for the third reading. The Bill authorises an extension of the Central London Railway from the present terminus at the Bank to Liverpool Street.

L.C.C. TRAMWAYS BILL.—This Bill was under consideration by a committee of the House of Lords last week, and was reported for third reading. The two proposals which were seriously opposed in the House of Lords related to the tramway down Farringdon Road, and the reconstruction of the Highgate Hill Tramways for electric traction. With regard to the first, the House of Commons Committee allowed the proposed line to have its terminus at the junction of Farringdon Road and Charterhouse Street, which it was argued would practically kill the trade carried on by the costermongers in Farringdon Road. The House of Lords, however, have ordered that the terminus shall be next to Farringdon Street station. With regard to the Highgate Hill tramway, the opposition in this case came from the owner of Fairseat House, which it was proposed to acquire for the purposes of widening. In this case, also, the House of Lords has reversed the decision of the House of Commons, having decided that the County Council shall only acquire so much of the property as is necessary for the street widening, and not the whole of it.

PROGRESS OF ELECTRICAL BILLS.—The following Bills were read a third time and passed in the House of Lords on Monday :—Torquay and Paignton Tramways; Folkestone, Sandgate and Hythe Tramways; Oxford and District Tramways.

The N.E. London Railway Bill was read a third time and passed in the House of Lords on Thursday.

APPOINTMENTS AND PERSONAL NOTES

A proposal to increase the salary of Mr. J. H. Bolam, Borough Electrical Engineer at Weymouth, has been referred back.

The Electricity Committee of the Burslem Council recommended at the last meeting of the Council that the salary of Mr. Ashton Bremner, the electrical engineer, should be increased from £350 to £400 per annum. The recommendation, however, was ruled out of order.

The salary of Mr. Calvert, electrical engineer, of Finchley, is to be increased from £475 to £500 per annum.

Epsom District Council has appointed Mr. A. C. Gilling as resident electrical engineer at a salary of £200 a year, to be increased by annual increments of £10 each to £250 per annum. Mr. Gilling has been second assistant, and subsequently first assistant to the undertaking.

COMPANIES' MEETINGS AND REPORTS

CROMPTON & CO.—The directors' report for the year to March 31st states that the depression in trade and the resulting keen competition has rendered the obtaining of remunerative orders a matter of very great difficulty, and a certain amount of work has had to be undertaken at a very small margin over cost. The net profit amounted to £10,051, as compared to £51,320 for the previous year, and after providing for debenture interest and other charges there remains, with the sum brought forward from last year, an available balance of £7,828. It is proposed to set aside £1,500 for doubtful debts and contingencies, and to carry the balance forward. The directors have in view some important orders which it is hoped will be secured at satisfactory prices; they also have pleasure in reporting that during the financial year a patent has been obtained for a new auto-converter, invented at the company's works. Orders for these machines are now being executed, and it is anticipated that the invention will prove of considerable importance to the company's business. With a view to obtaining fresh capital until such time as the company can profitably reduce its holdings in other concerns, an offer of short term notes was made to the shareholders in February last. The directors are now offering elsewhere the balance unapplied for. The meeting is on Monday.

ELECTRIC CONSTRUCTION CO.—The report and accounts given in our issue for July 8th were adopted at the annual meeting on Wednesday. Mr. W. S. B. McLaren, chairman of the company, who presided, said that the keen competition of the past few years had compelled the directors to give the closest attention to economical production. The result was that labour-saving plant had been installed, which had placed the company in a position to produce electrical machinery second to none. The past year's results would have enabled a 2½ per cent. dividend to be paid on the ordinary shares, but for the necessity of having to pay two years' dividends on the preference shares. The past year's trading, however, had been the best since 1904, and, in the absence of any further slump in trade, the current year would show results equally favourable. The Electrical Power Storage Co., in which the Electric Construction Co. was largely interested, found itself, for the first time in 17 years, unable to declare a dividend, but there were indications of a revival of trade in this industry. A better return, however, had been received from their holding in the Madras Electric Tramways Co. In the opinion of the Board, the company's position generally had been greatly improved during recent years, and justified them in looking forward to the future with every confidence.

VICTORIA FALLS & TRANSVAAL POWER CO.—Mr. H. Birchenough, C.M.G., presided at the annual general meeting on Friday, in the absence of the chairman, Lord Winchester, who is now on his way back from South Africa. The report and accounts given in our last issue were adopted, and the chairman's speech did not add a great deal to the statements made therein. He emphasised the fact that the company was still in the constructional period, and referred to the arrangements with the Rand Mines Power Co., as the result of which new capital was issued to the extent of £900,000 five per cent. debentures, which were guaranteed by German banks. The position as between the Victoria Falls Co. and the Rand Co. is that the latter will be a separate organisation, but the whole of the shares will be held by the former. At present the greatest difficulty the company had to contend with, said the chairman, was to connect up consumers fast enough. In answer to questions as to power transmission from the Falls, Sir Charles Metcalfe said this would have to be deferred on account of the great opposition of the railway companies, who depended a great deal for their income upon the carriage of coal, and also by other people interested in the coal mines. It would give him the greatest gratification to carry the scheme through, however.

EDMUNDSON'S ELECTRICITY CORPORATION.—At the annual meeting on Thursday, the report and accounts given in our last issue were adopted. Mr. P. D. Tuckett, who presided said that the prevailing conditions of the past year had undoubtedly been peculiarly adverse, not only for them, but for almost all similar businesses; and though he saw no reason to suppose that they would not continue to make steady progress, he thought it would be unwise to anticipate that that progress was likely to be otherwise than slow. Costs were now in most cases reduced within measurable distance of the limit of possible reduction, whilst the increasing use of the more efficient lamps was not at the moment conducive to a rapidly expanding revenue.

GENERAL ELECTRIC CO.—Mr. G. Byng presided at the annual meeting on Monday, when the report and accounts given in our last issue were adopted. He stated that whilst the pressure of competition at home was forcing them to seek orders more and more abroad, unfortunately Customs duties were acting against the company, not only on account of their stiffness, but also on account of their uncertainty, and it would be of enormous assistance if the British Government would enter into commercial treaties with Continental nations instead of relying upon the so-called "most favoured nation" clause. He was pleased to record that their telephone equipments were being adopted by the British and Colonial Governments, and were considered an advance upon those made by the most prominent manufacturers in America and on the Continent. The sale of Osram lamps had been very large, the factory at Hammersmith being completed and turning out these lamps in every respect equal in quality to those produced on the Continent. He thought it was a deplorable fact that whilst Great Britain was importing £200,000,000 worth of manufactures, all our large factories were being worked below their productive capacity, a state of affairs due, he said, to our fiscal system.

Institution of Mining Electrical Engineers.—Meetings of the Yorkshire and Notts branches of the newly formed Institution of Mining Electrical Engineers will be held on Saturday next, July 24th, at the Victoria Station Hotel, Sheffield, and the Welbeck Hotel, Nottingham, respectively, both at 5 p.m. The business on the agenda at each meeting will be the appointment of local officers, &c., and all those locally interested in the formation and progress of the Institution are invited to attend.

Institution of Electrical Engineers.—A special general meeting of members, associate members, and associates of the Institution will be held at the offices of the Institution, 92 Victoria Street, London, S.W., on Thursday next, at five o'clock in the afternoon, for the purpose of considering, and, if approved, of passing the following resolutions, namely :—(1) "That the action of the Council in borrowing the sum of £26,000 from the Economic Life Assurance Society on the security of the leasehold property of the Institution on the Thames Embankment on the terms of the indenture of mortgage dated June 1st, 1909, a copy of which is now produced to the meeting be and is hereby authorised and confirmed." (2) "That an expenditure of a sum not exceeding £20,000 on structural alterations, furniture, and fittings in connection with the Institution building be sanctioned and approved, and that the Council be authorised to make such financial arrangements (including the borrowing of money on the security of the Institution building and of the Institution property in Tothill Street) as the Council may consider necessary for the above purpose."

THE PHYSICAL SOCIETY

New Methods of Electrical, Thermal, and Magnetic Measurement

AT a meeting of the Physical Society on June 25th, Mr. A. Campbell read a Paper "On the Measurement of Wave Length for High-frequency Electrical Oscillations." The experiments had for their object the calibration of wavemeters for the measurement of the high frequencies (200,000 up to 1,000,000 cycles per sec.) used in wave-telegraphy. Two wavemeters were tested, both being of the type consisting of a series of self-inductance coils used singly in series with a variable air-condenser and a thermo-ammeter. The capacity of the variable condenser was altered until the circuit showed resonance with the working circuit. The coils of one wavemeter were wound with solid wire, those of the other with stranded wire (7/36s), each strand being separately insulated. The absolute value of the frequency was determined by photographing spark-trains in the primary circuit by means of a rotating mirror running at a constant and accurately measured speed. The value of the frequency deduced from the measured values of the capacity and self-inductance with the wave meter with stranded wire were in close agreement with the actual n deduced from the spark-photographs. With the wavemeter wound with solid wire the agreement was naturally not nearly so close, but was much improved when the values of the self-inductances of the solid wire coils were corrected to the high-frequency values by the formulæ of Heaviside and L. Cohen. The results show that the inductances of the stranded wire coils are practically unaltered for frequencies from 0 up to 1,000,000 cycles per sec.

At the same meeting, Dr. C. V. Drysdale exhibited a new Fery thermo-electric calorimeter. This form of calorimeter can be used continuously, and permits the value of the gas produced in a gas-works or producer-plant to be watched from time to time. The principle of the instrument is that of burning the gas to be tested at a constant rate in a special burner consuming from 5 to 10 litres per hour. This burner heats a recuperative thermopile, of which the cold junction is traversed by the air employed for the combustion, while the hot junction is heated by the products of combustion. The thermopile contains 15 junctions, which enables a P.D. of 0·2 volt to be obtained. The energy produced is sufficient to obtain a trace with a recording instrument similar to that obtained with the Richard recording thermometers and barometers.

A Paper by Mr. F. W. Jordan on "An Instrument for Measuring the Strength of an Intense Horizontal Magnetic Field" was also read. The method consists in measuring directly the transverse force on a conductor traversed by a current in a direction at right angles to the field. Two copper strips of uniform width, each cut to form three sides of a rectangle, are fastened together and connected by short tinsel leads to terminals, so that the current can be sent in the same direction through each of the insulated conductors. The framework is suspended in the field to be measured from a helical spring of phosphor-bronze. The tension in the spring can be adjusted to bring the framework into a sighted position. To make a measurement the horizontal conductors are arranged at right angles to the field and a known copper weight is suspended from the centre. A current is passed through the wires and its strength adjusted until the framework is again in its sighted position. The strength of the field is then easily calculated. The results obtained with the apparatus, using fields from 1,000 to 13,000 gausses, agreed with those got by the ballistic method to 1 part in 400.

CATALOGUES AND PAMPHLETS, &c., RECEIVED

[*Readers applying to any of the under-mentioned firms for copies of the catalogues or pamphlets referred to are requested to mention "Electrical Engineering."*]

BATTERIES FOR CENTRAL STATIONS.—Those central station engineers who are contemplating following the example of Manchester and installing a battery to deal with peak loads, will do well to ask the D.P. Battery Co., Ltd. (Bakewell, Derbyshire), to send them a copy of a pamphlet just issued dealing with this question. The possible economies are worked out and explained with the assistance of diagrams and figures of costs.

ELECTRICAL PLANT AND APPARATUS.—Recent lists issued by the A.E.G. Electrical Co. of South Africa, Ltd. (agents for the A.E.G. Foreign Department), include those dealing with slow-speed three-phase motors, large three-phase induction motors, small continuous-current motors and generators; three-phase, two-phase, and single-phase induction motors, iron switch cases, electric annealing and tempering plants, lift-controlling gear, and the "express" electric water heater for heating water as it circulates through a system of tubes.

GLASS SHADES.—A new list from the Sun Electrical Co., Ltd. (118 and 120 Charing Cross Road, W.C.), illustrates a large variety of new designs, as well as known stock patterns of glass shades, including special shades for metal filament lamps both of high and low voltage.

RONTGEN-RAY APPARATUS.—A new supplement to the general catalogue of electro-medical apparatus issued by Messrs. Siemens Brothers & Co., Ltd. (Caxton House, Westminster), deals with apparatus designed for the purpose of producing Röntgen rays without inverse radiation. Alternating current is stepped up by means of a special transformer, and then converted into unidirectional current by means of a rectifier, rotated by a synchronous motor worked off the mains. Where continuous current only is available, this is converted into alternating current by means of a rotary converter, which also rotates the rectifier. The rectifier commutes the alternating current when its value is zero. Another supplementary pamphlet describes devices for protecting the practitioner and the patient from the harmful effects of the rays, and also for applying the rays themselves.

STEAM TURBINES.—A leaflet from the British Thomson-Houston Co. gives a list of vertical and horizontal Curtis steam turbines in service, and in course of construction.

FLEXIBLE STEEL-ARMOURED CONDUCTORS.—A list from the British Electrical & Manufacturing Co. (1 St. Nicholas Buildings, Newcastle-on-Tyne), gives particulars of "Greenfield" flexible steel-armoured single, twin, or triple flexible conductors for house wiring, &c. The armouring is composed of convex and concave metal strips wound spirally upon each other over the insulated conductors. A gasket is placed between the inner and outer metal strips, thus further rendering the conductor moisture proof. Flexible steel conduit is also made of similar construction, and a complete series of junction boxes and other fittings are listed, as well as special tools for installation of this class of material.

COST OF ELECTRICITY FOR HOUSE LIGHTING

THE July issue of the *West Ham Bulletin* gives the following particulars of the electric lighting bills for the year to March 31st, 1908, and its consumers in Windsor Road. In all cases the consumers have found a reduction in their lighting bills compared with gas. It may be mentioned that in the case of No. 1,261, four table lamps, one standard lamp, and a small desk fan were also in use, and in the case of No. 437, an electric flat-iron was also used.

Reference No.	Number of Lamps. Carbon. 8	16	32 c.p.	Tantalum. 25	32 c.p.	Osram. 32	50 c.p.	Total cost. £	s.	d.

New Engineering Laboratories at Manchester.—An extensive series of new engineering laboratories, forming extensions to the engineering department of the Victoria University of Manchester, were opened by Sir Alexander Kennedy on Thursday last. The buildings include the new Whitworth Laboratories, devoted to thermodynamics, hydraulics, and strength of materials, with fine equipments, and the Osborne Reynolds research laboratory, together with workshops and new drawing offices.

Electricity in Mines.—In his report on the Southern mining district for 1908, the inspector, Mr. J. S. Martin, in dealing with the use of electricity in mines, remarks that rapid strides are being made in the adoption of electricity in the mines throughout the district in Cornwall, Gloucestershire (Bristol and the Forest of Dean), Kent, Monmouthshire, and Somersetshire. It is used for pumping, underground haulage, and the working of about a dozen coal-cutters. According to the *Iron and Coal Trades Review*, in which the report is abstracted, he does not recommend the working of electric coal-cutting machinery at the working face in the fiery mines of Monmouthshire, but favours the use of air compressors underground as far in-bye in the intake airway as it may be safe to work electrically, to supply compressed air to the coal-cutters at the face. Electricity had been a disappointment to some people, more especially in Cornwall, but he considered that the explanation was that the parties obtained their generating plant from the makers without having had the scheme gone into by an efficient and experienced electrical engineer on their own behalf, in order to see whether it was suitable for the proposed work, with the result that they had not got the necessary power, or the work satisfactorily carried out.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published July 15th, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

13,185/08. **Automatic Transformer Switch.** LEO SUNDERLAND and G. C. PULLINGER. This is a switch for automatically disconnecting transformers when no lamps are in use, and reconnecting when the first lamp is switched on. The pilot circuit contains a battery, and the principal feature of the switch is the combination of a spring or gravity controlled arm carrying contacts which open and close the primary and secondary supply switches, and also a contact which closes an auxiliary circuit to energise an electromagnet which directly operates the switch arm only during the closing of the switch, the switch being held on by a separate electromagnet in the secondary circuit. Two claims, three figures.

13,327/08. **Electromagnetic Switch.** R. F. VENNER, R. C. GRIESBACH, and D. K. MORRIS. In this automatic switch, which is adapted for opening and closing by an auxiliary clock switch or otherwise, the main switch arm is provided with a supplemental spring or gravity controlled arm, which makes contact with it, to allow current to pass through the coils of the operating magnet or solenoid for closing the switch. This supplemental switch arm is maintained in contact with the main switch arm, and the current is allowed to pass through the operating coil for just the period necessary to close the switch. Four claims, five figures.

13,504/08. **Short-circuited Rotors.** LANCASHIRE DYNAMO & MOTOR COMPANY and R. S. MCLEOD. In this improved method of attachment of the end rings of squirrel-cage induction motors, several rings of thin sheet material are used at each end, and a number of lugs are formed in the periphery of each ring, and these are twisted through a right angle and adapted to fit into saw cuts in the bars. The lugs also space the rings apart and form radial ventilating ducts of use in cooling the end connections. Three claims, eight figures.

14,773/08. **Switch for Power Circuits.** G. COOPER and F. C. SHARP. An electromagnetic device is fitted to this switch, so arranged that the switch cannot be retained in the closed position unless a current of a predetermined minimum value has passed at the moment of switching on. The object of the appliance, which can also be adapted to switches closed by pushing in a wall plug, is to prevent lighting being carried out from power circuit. Six claims, four figures.

15,388/08. **Separators for Accumulators.** VAN RADEN & CO., LTD., and M. METZ. These separators for accumulator plates consist of rigid tubes of insulating material split longitudinally so as to be a sliding fit on the edges of the plates. The tubes are of greater diameter than the thickness of the plates, and are arranged so as to leave them freely exposed to the action of the electrolyte. The separators at the same time serve to support the plates and hold them rigid. One claim, five figures.

17,161/08. **Leakage Indicator for Mines.** ASHINGTON COAL COMPANY and T. MCKIE. In this arrangement, which is adapted to three-phase systems, a separate leakage return circuit to the neutral point of the main generator is provided to each main circuit, connected so that the leakage current flows through a coil which actuates a drop weight for knocking off the main switch or similar releasing device. The leakage current also actuates a tell-tale, or indicator, on each leakage circuit, which closes a relay circuit controlling a lamp indicator in the generating station. A recording ammeter is placed in the main leakage return circuit, and also a choking coil and fuse. Five claims, one figure.

21,956/08. **Continuous-current Dynamos.** A. H. MIDGLEY and C. A. VANDERVELL. With the object of reducing weight of the field system, these machines are provided with a second annular ring armature mounted upon a suitable frame carried by the inner armature shaft, and a single-field system occupying the space between the two armatures. Two claims, one figure.

23,903/08. **Electrical Driving of Planing Machines.** VICKERS, SONS & MAXIM and A. D. WILLIAMSON. This relates to the class of electrically driven planing machine in which a variable speed reversing motor is started, stopped, and reversed with the table. Instead of using separate switches worked mechanically from the table, a combined reversing and starting switch is employed, which is controlled electrically by a motor switch that receives its movement from the reciprocating table. Six claims, four figures.

27,343/08. **Alternating-current Meter.** SIEMENS-SCHUCKERTWERKE-GES. This alternating-current motor is of the induction type, having a laminated iron core for the potential winding, which is nearly closed, and is provided with a magnetic shunt path and a U-shaped laminated iron core for the main winding. The characteristic feature is that the distance between the limbs of the latter core is equal to, or only slightly greater than, the thickness of the potential core. Three claims, three figures.

Opposition to Grant of Patents

6,716/08. **Boiler Flues.** A. A. DAY and W. J. H. WOOD. The grant of this patent, which is for an improved method of constructing brick arches in Lancashire and similar boilers by building them up of separate sections, has been refused in consequence of opposition.

9,463/07. **Electrolytic Meters.** B. NORTH. A grant has been allowed on this application in spite of opposition. The patent is for a special form of outer casing to the vessel containing the electrolyte, designed so as to give ample cooling surface.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad. Summaries of some of the more important of these patents will appear in our next issue.

Arc Lamps: KÖRTING, 4,122/09; BLECKLY and BROWN, 9,516/09.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: BEAVER and CLAREMONT [Cables] 20,447/08; STRATTON and CLAREMONT [Connectors] 26,796/08.

Dynamos, Motors, and Transformers: A. G. BROWN, BOVERI & CIE [Automatic regulation] 19,992/08.

Electric Ignition: BELL 19,883/08.

Electrometallurgy and Electrochemistry: MASON [Prevention of rusting of electroplated articles] 13,715/08; BRITISH THOMSON-HOUSTON Co. (*General Electric Co.*) [Electrolytes] 15,792/08; HUTTON & HUTTON [Electroplating] 18,246/08.

Incandescent Lamps: BRITISH THOMSON-HOUSTON Co. (*General Electric Co.*) [Filaments] 23,726/08; SOC. FRANÇAISE D'INCANDESCENCE PAR LE GAS (*Système Auer*) 24,211/08.

Switchgear, Fuses, and Fittings: RITCHIE [Regulating device] 13,957/08; BRITISH THOMSON-HOUSTON Co. (*General Electric Co.*) [Lighting arrester] 22,135/08.

Telephony and Telegraphy: RITCHIE [Exchange system] 14,401/08; EISENSTEIN [Wireless telegraphy] 28,378/08.

Traction: TOMLINSON [Train diagrams] 11,752/08; BARRACLOUGH [Circuit-breaker] 14,463/08; ABRAHAM and GLENN [Signalling] 20,619/08; BRITISH THOMSON-HOUSTON Co. (*General Electric Co.*) [Signalling] 21,857/08.

Miscellaneous: CORNARO [Resistances for heaters, &c.] 13,734/08; COISEUR [Electric heating appliances] 22,551/08.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Arc Lamps: DUSCHNITZ, 11,579/09.

Distributing System: ARCIONI [Excess voltage preventer] 14,965/09.

Dynamos, &c.: SIEMENS-SCHUCKERTWERKE-GES., 9,048/09.

Electrometallurgy and Electrochemistry: SCHOTT AND CARL ZEISS STIFTUNG [Liquid anode] 14,288/09; SOC. ELECTROMÉTALLURGIQUE FRANÇAISE [Manufacture of nickel] 14,946/09.

Traction: COWDERY [Rail joints] 11,587/09; SOC. IN ACCOMANDITA PER L'UTILIZZAZIONE DELLE INVENZIONE ING. BEER [Signalling] 13,621/09; MERRITT and COBURN [Rail joints] 13,954/09; PATTERSON [Signalling] 14,925/09.

Miscellaneous: DE SAINTE-CLAIRE [Electrically controlled clutches] 13,234/09.

Expiring and Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

Arc Lamps: H. C. LEVIS, 7,660/04.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: E. A. CAROLAN (*General Electric Co.*) [Insulating fabric] 7,134/03.

Electrometallurgy and Electrochemistry: J. SWINBURNE and E. A. ASHCROFT [Electro-deposition] 6,857/01.

Electric Ignition: E. W. LEWIS [Ignition switches] 7,415/03.

Switchgear, Fuses, and Fittings: W. F. JONES [Switches] 6,819/99; W. R. LAKE [Circuit breakers] 6,635/01; E. A. CAROLAN (*General Electric Co.*) [Switches] 7,452/03.

Miscellaneous: OTIS ELEVATOR Co. [Electric lifts] 7,447/02; G. E. JAIFFE [Roentgen-ray apparatus] 7,489/04.

Restoration of Lapsed Patent Refused

Wireless Telephony.—An order was made on July 15th, dismissing the application by André Blondel, for the restoration of patent No. 15,527/02, relating to wireless telephony with Hertzian waves.

"Electrical Engineering," although the Cheapest Electrical Paper (Price 1d. weekly), contains the Most Useful and Practical Articles, the Best Illustrations, and the Latest News. It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.

SUMMARY

The following books are reviewed in this issue:—"The Internal Combustion Engine," by H. E. Wimperis; "The Life Story of Sir Charles Tilston Bright," by Charles Bright; "Essays Biographical and Chemical," by Sir William Ramsay; and "A Handbook of Electrical Testing," by H. R. Kempe. (Page 681.)

The most recent metal filament lamp to be placed on the market is the new 25-c.p. tantalum lamp for voltages from 200 to 240. (Page 682.)

The question of lowering insurance premiums on ships fitted with wireless telegraph apparatus is to be discussed by the International Conference of Underwriters. (Page 682.)

An electrically-heated "conditioning" oven for drying and estimating the moisture in samples of textile goods has been designed by Messrs. Ellis and Allsopp, of the Bradford Electricity Supply Department. (Page 683.)

A new starter for small printing machine motors is described on page 684.

Under Electrometallurgy and Electrochemistry will be found an account of the electrometallurgical exhibit at the Imperial International Exhibition of Messrs. Cowper Coles & Co., and some other exhibits of an electrochemical nature. (Page 684.)

An action for infringement of patent is being brought by the "Z" Electric Lamp Manufacturing Co., Ltd., against Messrs. Marples, Leach & Co. In the Chancery Division last week an application was made by the "Z" Lamp Co. for further information in amplification of the defendants' pleadings, but it was unsuccessful. (Page 685.)

A correspondent has sent us a letter from a firm of gas-engine makers, making somewhat unjust comparisons of the costs of electric and gas power. (Page 666.)

Mr. E. Garcke writes that the amendments made in the Electric Lighting Acts (Amendment) Bill have removed some of his objections expressed in a former letter. (Page 686.)

A few notes by Mr. E. W. Moss are given of the recent visit of the students of the Institution of Electrical Engineers to Germany. (Page 687.)

Digitized by Google

IN the course of a speech made at Hull on Thursday last, the Postmaster-General expressed the opinion that it would be desirable for the Government to take over all the land wireless stations at once, instead of waiting until the end of the three years yet to run under the original licences. Mr. Marconi has stated that the offer made by the Post Office to the Marconi Company was quite inadequate, and has not been accepted. (Page 688.)

THE annual report of Mr. F. Sumner, the Engineer to the City of London Corporation, deals, among other things, with street lighting and overhead wires. There are now 398 "open" arcs in the City of London, costing £26 per lamp per annum, and, in addition, 34 Oliver flame arcs and 18 Reason enclosed arcs, all of which are used in connection with the experimental lighting. The number of private owners of overhead wires is now 137, and the number of companies 23, there being now a total of 733,828 spans. (Page 688.)

AT the annual general meeting of the National Telephone Co. the President stated that the company were willing to undertake constructional work, which would be productive after 1911, provided the whole cost of this was borne by the Postmaster-General. With regard to an earlier purchase of the company's business than 1911, the company would expect to be fully compensated in respect of the profits of the years so surrendered. (Page 688.)

IN connection with the voluntary liquidation of Mountain & Gibson, Ltd., the receiver has indicated his inability to carry out completely certain contracts with the L.C.C.—The question of the price to be paid for energy by the Brighton Tramways Committee to the Electricity Committee is to be fought out in the Council, owing to a disagreement between the two Committees.—Fulham Council propose to fit 144 tramway poles with metal filament lamps.—The Morecambe Corporation electrical undertaking is to be specially reported upon.—The Preston Corporation are recommended not to purchase the undertaking of the National Electric Supply Co.—There is a net profit of £2,297 on the Portsmouth tramway undertaking for last year.—A special inquiry is to be conducted at Exeter into the charges which should be made for power supply.—The Altrincham telephone exchange has been equipped on the central battery system. (Page 689.)

A LOAN of £1,000 for gas-driven generating plant has been sanctioned to the Bray Council. A loan for excess expenditure has been refused. Three water-tube boilers are required by the Bury Corporation; mains are to be extended at Woolwich, and the installation of considerable sub-station plant is recommended at Walthamstow. A Local Government Board inquiry has been held at Derby concerning a loan of £7,300. Three five-wire balancers are required at Manchester. (Page 690.)

AT the meeting of the City & South London Railway Co., it was stated that the directors had a scheme of reduced fares under consideration, in consequence of tramway and omnibus competition. Mr. J. Trotter, at the annual meeting of Messrs. Crompton & Co., deplored the fact that the Victoria Falls Power Co. had placed the orders for its electrical machinery in Germany. (Page 691.)

A PETITION by Messrs. Pritchetts & Gold, Ltd., for the compulsory winding-up of the London Electrobus Co., Ltd., has been adjourned over the Long Vacation. (Page 691.)

A BRITISH Consular report deals at length with the electrical industry in Berlin during the year 1908. During the early part of the year the manufacturing portion of the industry was well supplied with orders, but trade depression had an effect towards the close, an effect which was accentuated by the Reichstag proposals to tax electricity. Two "Electro Trustee Banks" were established during the year. (Page 693.)

THE tax on illuminating apparatus in Germany will come into force on October 1st next. Carbon filament lamps, consuming between 25 and 60 watts, will be taxed to the amount of 2·4d. per lamp, and lamps taking between 60 and 100 watts, 3·6d. per lamp. The tax on metal filament lamps and Nernst glowers is 2·4d. each for 15 to 25 watt lamps; 4·8d. each for 25 to 60 watt lamps; and 7·2d. each for 60 to 100 watt lamps. Plain arc lamp carbons will be taxed to the amount of 3·27d. per lb.; impregnated carbons, 5·45d. per lb. (Page 693.)

AMONG the specifications published by the Patent Office on Thursday was one by C. J. Beaver and E. A. Claremont for cables with copper and aluminium strands, the latter being placed next to the rubber insulation, as the action between aluminium on rubber is less than that of copper. Heating elements for heating and cooking apparatus, comprising metallised carbon filaments run at a dull red heat in exhausted crystal tubes, are patented by E. Coiseur. The British Thomson-Houston Co. and H. H. Needham have protected a cadmium-bismuth amalgam used in manufacturing tungsten filaments. A specification by Körting describes a method of reducing the chattering of A.-C. arc lamps by putting damping rings on the armatures or plungers of the magnets; and another by H. P. Bleckly and W. Brown relates to the working of the "Abbey" arc lamp. Opposition has been entered to the grant of patents to Siemens & Halske A.-G. for means of making ductile metal filaments by coating the tungsten particles with a ductile metal, and to the Centralstelle für Wissenschaftlich-Technische Untersuchungen Ges. for the production of long arcs. A patent by A. C. Brown and G. R. Neilson for an electric fire alarm expires during the current week after its full life. (Page 694.)

Electric Traction in France.—The P.L.M. (Paris-Lyon-Méditerrannée) Railway Company intends, in conjunction with the Elektrizitätsgesellschaft Alioth of Basle, to convert the main-line section between Cannes and Ventimiglia to electric traction. A short section from Grasse to Mouans-Sartoux will be equipped at once for experimental purposes; this section is especially suitable on account of the heavy gradients and sharp curves, and the fact that there is not much traffic on this part of the line. According to *Elektrische Kraftbetriebe und Bahnen*, the overhead equipment (for 12,500-volt single-phase) will be carried out on a patent multiple-catenary system of the Alioth Co. Wooden poles are to be used on the experimental section, but eventually steel girder supports will be adopted. The first locomotive will have four driving axles and a bogie-truck at either end. It will be about 65 ft. long and will weigh about 140 tons. A drawbar-pull of some 16,000 lbs. at 38 miles per hour, and 10,600 lbs. at 62 miles per hour. The locomotive will contain an Auvert and Ferrand permutator, which will convert the alternating current to continuous current at any pressure between 0 and 600 volts. Each driving axle will be geared to a 450-h.p. continuous-current motor.

Telegraph Traffic and Movements of Cable Ships.—The diversion of the two cables of the Commercial Cable Company from Canso, Nova Scotia, to St. John's, Newfoundland, now being undertaken, will put them out of use for some time.—The line between Teheran and Hanekin was down on the 26th inst. between Hamadan and Kirmanshah.—The Chinese and Japanese Administrations reopened the Dairen-Chefoo cable on the 20th inst., while on the 21st the line between Bagdad and Bassorah was broken.—The reduced rate of 9d. per word conceded by the Pacific Cable Board on Press matter between Great Britain and Australia comes into force on August 1st next.—The Commonwealth Government states that the cables of the Eastern Extension, Australasia and China Telegraph Company, between the Continent and Tasmania will be lifted soon by the owners, thus leaving only the Government system to perform the telegraphic work.—The cable steamer *Minia* left Halifax, N.S., for a repair on the 2nd of last month, and returned on the 8th. She left for England four days later, and was passed in mid-Atlantic by the cable steamer *Mackay Bennett*, engaged in the diversion of the cables of the Commercial Cable Company.—The French Cable Company's repairing steamer, the *Contre-Amiral Caubet*, which was engaged for some time off the Flemish Cap repairing cables, returned to Halifax, and left on the 25th ult. for a repair on the New York section.

REVIEWS OF BOOKS

The Internal-Combustion Engine. By H. E. Wimperis. 82 pp. 8½ in. by 5½ in. 114 illustrations. (London: Archibald Constable & Co.) 6s.

THIS book consists of two parts: a theoretical and a practical. In the former the author has done some good work, notably an original investigation of the effect on the thermo-dynamic efficiency of the internal-combustion engine of the now accepted increase in specific heat of the products of combustion with temperature. The practical part, however, is hardly so satisfactory, being in considerable measure extracts from other works or from the published proceedings of various societies; on the other hand, it is useful to have these scattered opinions and information collected together, and, on the whole, a correct picture of the internal-combustion engine is given to anyone who does not want to go very deeply into the subject.

At the beginning of the book there is a useful table of constants followed by a table of the chief symbols used, a feature which cannot be too highly recommended in a book of this kind. We note, however, that θ is used for the temperature as read by the thermometer, which is unusual, and by many writers this symbol is reserved for absolute temperature. We also note that "British thermal unit" is contracted into B.T.U., and, as the author is an associate member of the Institution of Civil Engineers, he ought to know that that Institution has decided to use the contraction B.Th.U.

The first chapter treats of thermo-dynamic cycles, and the author proves that, whether the cycle be of the constant volume, the constant pressure or the constant temperature type, the thermal efficiency is the same for the same ratio of compression, supposing the specific heat to be constant. In Chapter IV. there is an excellent *résumé* of the present state of knowledge in respect to the increase of specific heat of gases with temperature, and, as already indicated, the author obtains, after a lengthy mathematical investigation, a comparatively simple expression for the constant-volume cycle on the supposition that the specific heat of the products of combustion increases according to a linear law. A numerical example is worked out in which it is shown that the thermo-dynamic efficiency of a perfect gas engine, having a compression ratio of 7, is 0·44 instead of 0·54, according to the "air standard." It is to be noted that the Carnot cycle for the same range of temperature is over 80 per cent., and it is not many years ago that this high efficiency was deemed theoretically possible. In this same chapter the flow of heat through cylinder walls is discussed, and it is interesting to note that the numerical results arrived at are in close agreement with recent experiments. In Chapter V. gas engines of various types are described in a somewhat cursory manner. A mathematical analysis of the motion of the indicator piston is given, and an expression is obtained co-relating the frequency of the instrument with the time of the explosion. The testing of gas engines, heat balances, flywheel effect, and the balancing of an engine are dismissed in a few words; nevertheless, a clear view of the matter is given. The gas producer is dealt with in Chapter VI., but the theory is discussed in a superficial manner, and a really correct view of the reactions and temperatures occurring in a gas producer is not given.

The third and last section of the book, consisting of two chapters, is devoted to oil and petrol engines. The Campbell and the Diesel engine are described as representatives of the slow-speed oil engine, and the Albion and the Lanchester engines as representatives of the petrol engine. Several pages are devoted to carburettors, and the mathematical theory of jet carburettors is given. The rating of petrol engines is also discussed at some length. Each chapter throughout the book is followed by a number of problems for solution taken from various examination papers. The book is well illustrated by a large number of clearly-drawn illustrations.

The Life-Story of Sir Charles Tilston Bright. Revised and Abridged Edition. By Charles Bright, F.R.S.E. 467 pp. 8½ in. by 5½ in. (London: Archibald Constable & Co.) 12s. 6d.

IN view of last year having been the fiftieth anniversary of the completion of the first cable establishing telegraphic communication between Great Britain and America, Mr. Charles Bright and Messrs. Constable had the excellent idea of bringing out an abridged edition of the monumental biography of Sir Charles Bright published in 1898. The abridged edition, which appeared last December, should be in the library of every telegraph engineer who has not the good fortune to possess the larger work. Without in any way wishing to detract from the original parts of the book, we must confess that the most interesting and fascinating sections of the volume are the copious extracts from the articles written by Mr. Nicholas Wood, *The Times'* correspondent who accompanied the expedition which laid the first Atlantic cable. This finely-written account of the untiring energy and perseverance of Sir Charles Bright, and the enthusiasm which he inspired in all around him in the face of a sequence of calamities, speaks far more eloquently than anything that could be written after his results had been achieved and their full value had been realised.

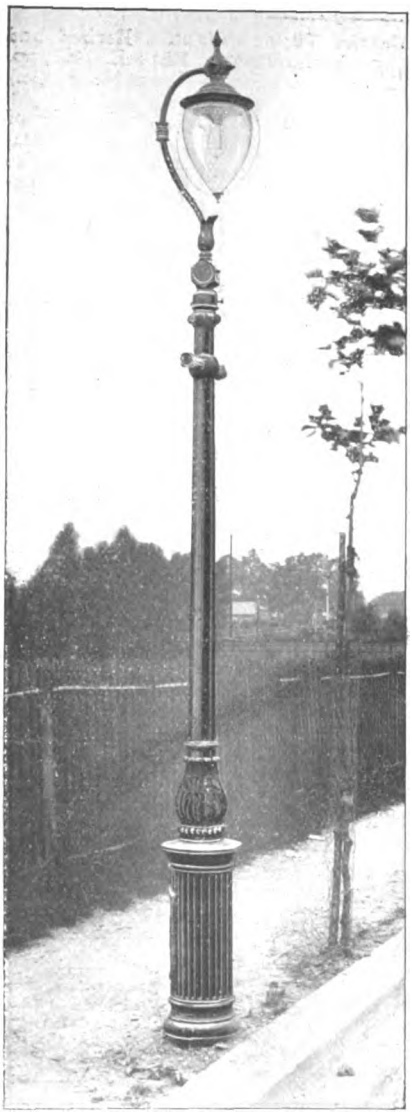
Essays Biographical and Chemical. By Sir William Ramsay, K.C.B. 247 pp. 8¾ in. by 5½ in. (London: Archibald Constable & Co.) 7s. 6d.

THIS volume commences with historical essays, connected with the early days of chemistry. It is first shown that in the early days of the world's history the study of science was not known. But as time passed certain arts, such as dyeing and metallurgy, useful for practical purposes of life and founded on chemical principles, began to be cultivated. The author traces in an interesting manner the way in which one discovery led on almost imperceptibly to another. There were always those who found that the practice of things which were unknown to others and in the earlier years appeared mystic, gave them an authority not possessed by the ordinary run of men. The scientific spirit, however, was absent; "people were content to take as true what they were told." But whether it was in order to mystify or because the seekers tried to transmute baser substances into gold, steps forward were gradually made until men began to want knowledge for the sake of knowledge.

The next section deals with the great London chemists, the first of the section being Boyle and Cavendish. The short biography of the two men, each a pioneer, is very interesting. Boyle has been termed the father of modern chemistry, but Cavendish, by weighing the earth and showing the constitution of water, is even more entitled to this claim. We then come to Davy and Graham, the former a marvellous experimenter and greedy of fame, the second a careful and industrious worker of a most modest and retiring disposition. The work of Joseph Black is next reviewed, then that of Lord Kelvin and Berthelot. These biographical studies occupy about one-half of the book; the second half is devoted to chemical essays.

The first of these is entitled "How Discoveries are Made." Ramsay thinks that it is often supposed discoverers are born, not made; but he considers that many people are capable of making discoveries. It will do the pessimist and the sneerer at scientific discovery good to read this chapter. Other subjects treated of in the book are "The Becquerel Rays," "What is an Element?" "The Periodic System," "Radium and its Products," "What is Electricity?" and finally "The Functions of a University." This book should be found of interest to those engaged in scientific occupations, and also to those who have no actual acquaintance with chemistry.

A Handbook of Electrical Testing. By H. R. Kempe. Seventh Edition. 706 pp. 8½ in. by 5½ in. 285 illustrations. (London: E. & F. N. Spon, Ltd.) 18s. net.



WHEN the first edition of Mr. Kempe's handbook was written, electrical testing meant the testing of cables, batteries, and galvanometers; and the author, while retaining the title in his seventh edition, has not extended the scope of his work, which remains a text-book and a book of reference for the cable and telegraph electrician. The present edition shows signs of considerable revision, especially by the inclusion of descriptions of more recent patterns of instruments.

CATALOGUES AND PAMPHLETS, &c., RECEIVED

[Readers applying to any of the under-mentioned firms for copies of the catalogues or pamphlets referred to are requested to mention "Electrical Engineering."]

STREET LIGHTING FITTINGS FOR METAL FILAMENT LAMPS.—Mr. Haydn T. Harrison (11, Victoria Street, Westminster), who has for long made a special study of street illumination, has sent us a copy of a booklet which contains illustrations of various patterns of street lighting posts and other fittings for high candle-power tungsten lamps, of which he has supplied a considerable number during the last twelve months to several important towns. These consist in some cases of fittings for the conversion of gas lamp posts for taking metal filament lamps, but complete posts are also listed, and the designs are simple, effective, and artistic. The example illustrated herewith is for single tungsten lamps, and is in use at Croydon. Fittings are also made for two or more lamps. The booklet also illustrates brackets both for the wall and for attaching to tramway poles, and outfits, with special reflectors, for converting existing gas lanterns, together with various accessories, including switch-fuses, time-switches, &c. Some tables and useful data relating to street lighting and electricity are also given.

HARRISON TUNGSTEN LAMP FITTING AT CROYDON.

DYNAMOS, MOTORS, &c.—The Phœnix Dynamo Manufacturing Co., Ltd., have sent us a copy of the new "Phœnix" Bulletin, which contains an interesting description of the company's Thornbury Works, Bradford, with some notes on the methods in use there, and gives a series of excellent illustrations of different types of machines which are manufactured there, including continuous-current and three-phase generators, motors and motor generators, together with some typical examples of the application of Phœnix motors to various classes of industrial machinery.

MAGNETIC SEPARATORS.—A description of the "Rapid" patent electromagnetic separator is given in a leaflet issued by Messrs. Cookson & Co. (Albion House, 59-61, New Oxford Street, W.C.). The newest type of machine is suitable for treating various kinds of dry materials containing iron in small quantities, and consists of a shoot, or tray, oscillating sideways about 250 times per minute by means of a reciprocating motion, in similar manner to a sieving machine. This shoot is built up of a series of very powerful electromagnets, extending across the full width of same, upon which the material is fed, passing over the electromagnets, where the iron is retained. By means of the reciprocating motion the material is shaken and rolled down the shoot, the iron being seized by the electromagnets and retained. To remove the iron it is only necessary to occasionally stop the machine, switch off the current, and clear the tray. This is only a moment's work. In another pattern the material is automatically fed in a constant stream on to the revolving brass drum, inside which, radiating from the centre, are fixed electromagnets. The magnetic field extends round one-half of the drum. On coming in contact the iron is seized by the magnets, and by means of the ridges on the revolving drums, is carried round to the back of the machine and out of the magnetic field, falling immediately by gravity.

PUMPS.—A new catalogue from Messrs. Merryweather & Sons, Ltd. (63 Long Acre, and Greenwich Road), describes this firm's well-known three-cylinder "Hatfield" pump, which is adapted for direct driving by electric motors or through gearing-chains, &c., and is suitable for fire protection, water-supply, boiler feeding, and a variety of other purposes. The three pump-barrels are arranged symmetrically round the motor shaft, and form part of a single gun-metal casting, in which are also formed the valve chambers and passages. Each pump piston is of large diameter, with short stroke. It is thus possible to run the pumps at speeds up to about 700 r.p.m. The valves used are of india-rubber of the special form adopted for fire-engines. In order to facilitate the starting of the motor a by-pass valve is fitted between the suction and delivery water passages.

A NEW HIGH VOLTAGE TANTALUM LAMP

MESSRS. DRAKE & GORHAM inform us that another new size of high voltage tantalum lamp is now being placed on the market which should be of considerable use in private houses where a high candle power is not required, as well as for hotels, warehouses, and other purposes. The new lamp is for continuous current circuits of 200 to 240 volts, and gives approximately 25 c.p. with a consumption of 42·5 watts, which corresponds to an efficiency of about 1·7 watts per candle. The lamps are made both with the ordinary bell-shaped bulbs, $5\frac{5}{8}$ in. long, and $2\frac{3}{8}$ in. diameter, and with spherical bulbs $5\frac{1}{2}$ in. diameter. This size of lamp, which is listed at 3s. 6d. in the bell-shaped bulb, and 3s. 9d. with spherical bulb, forms a smaller unit of light than the majority of 200 volt metal filament lamps, and it will be seen that its consumption is about three-quarters of that of the ordinary 16 c.p. carbon lamp, although the candle-power is more than 50 per cent. higher. We have also received a leaflet giving prices of the lamp from the manufacturers, Messrs. Siemens Brothers Dynamo Works, Ltd.

Rails for Electric Railways and Tramways.—At the annual convention of the Permanent Way Institution at Sheffield, in a Paper read on Saturday by Prof. McWilliam, of Sheffield University, reference was made to the increased wear on rails with the smaller wheels and low centres of gravity used with electric traction. He showed that by considerably increasing the proportion of manganese, steel was made tougher and able to withstand more wear; and how silicon had been increased with similar results. Nickel steel did not seem to have been a very great success, so far as rails were concerned, considering its cost. Mr. Willox (Chief Engineer to the Metropolitan Railway) said that his experience of the addition of silicon to rails, after a three years' trial, was that it increased the life of a rail by about 110 per cent. On steam railways, with the use of large wheels and springs, the life of a rail was 20 or 25 years, or more, but the moment they got a low centre of gravity, small wheels, the dead weights of motors and axles, and the extraordinary acceleration and deceleration, the life was reduced at once to about 25 months.

Wireless Telegraphy.—The question as to whether the insurance premiums on ships should be lowered when they are fitted with wireless telegraph apparatus will be discussed by the International Conference of Underwriters at Baden-Baden in September.

Correspondence in connection with the existing wireless stations at Trinidad is published in the Trinidad papers, wherein the Director of Public Works shows that if the North Post station is to be a permanent one, expenditure to the extent of £850 will have to be met. One hundred pounds was recently spent on repairs to buildings which will obviate expenditure for five years, when another £125 will put them again in good condition for a similar period. The same amounts apply also to Fort George installation. With regard to the Port of Spain station, an expenditure of £273 is required to tide the station over for five years, when an expenditure of £975 will have to be met. There is some suggestion of amalgamating the various services with a view of economy.

On June 26th the *Argosy* of British Guiana stated with reference to the wireless telegraphy installation of the West India & Panama Telegraph Company between Demerara and Trinidad that during a few days signals had been sent from the former station, but it was not known if they were received at Trinidad, neither were signals received from Trinidad. It is stated that bad weather has delayed the completion of the latter station, but it is expected communication may be effected at any moment, though some work may still have to be done in the way of tuning and adjusting. Mr. Blenheim, the Lodge-Muirhead expert, will again have to visit the station for this purpose. It is also confidently expected that the system will be in working order by the end of this month.

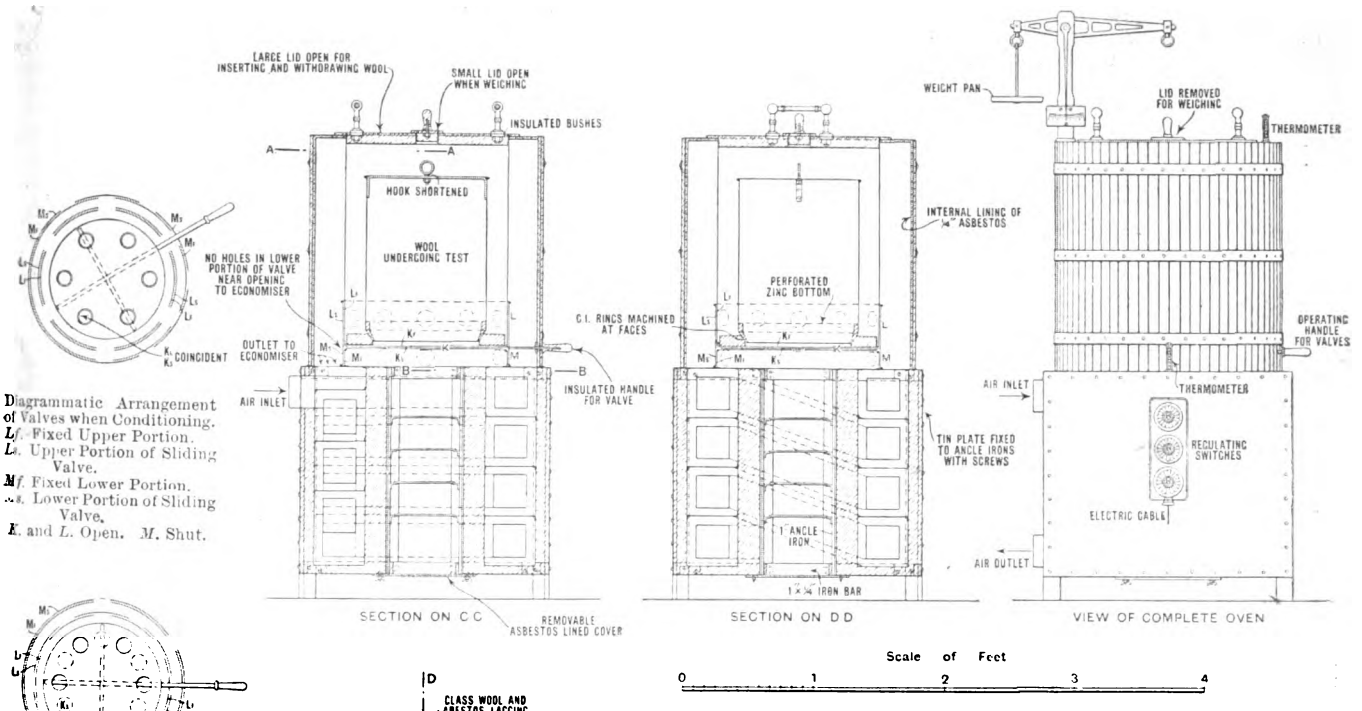
AN ELECTRICALLY HEATED CONDITIONING OVEN

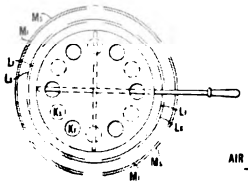
AN improved form of electric "conditioning oven," for use in the textile trade, has been designed by Mr. H. S. Ellis (Assistant Electrical Engineer to the Corporation of Bradford) and Mr. C. E. Allsopp (also of the Bradford electricity department), which is claimed to have several advantages over gas- or steam-heated ovens.

The object of the apparatus is to ascertain the percentage of moisture in any fabric which might be considered hygroscopic, as the presence of moisture not only affects the weight, but also the strength, so that it is unfair that tests of strength should be carried out unless the cloth has first been conditioned, as there are many cloths which have a lower breaking point when wet than dry.



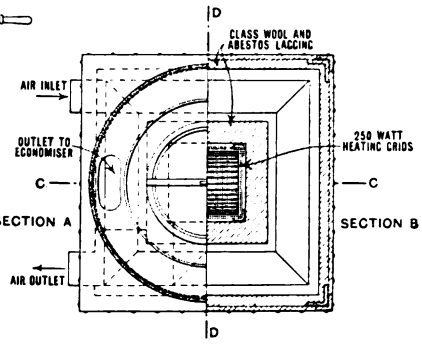
The conditioning oven ensures that the fibre or cloth is free from moisture, or, at any rate, that the percentage of moisture remaining is such as to be a negligible quantity when considering weight or strength.

The object of all conditioning ovens is the same, but their construction differs slightly owing to the heating medium, which up to the present has been confined to gas or steam. The steam oven is used only where a supply of steam is available for power or heating purposes, but, where steam is not available, gas is used. The efficiency of the gas-heated oven is naturally low, as the air passing through the wool must not be in contact with the flame or fumes. It is usually passed over a series of large copper plates on its way to the conditioning tank; this means, then, that by far the greater percentage of heat units passes away to the atmosphere. In most modern gas-heated ovens the hot air is driven through the wool by means of a fan or blower at a pressure such as will ensure that all moisture is taken away with it. If electric heating was applied in the same way the expense would prohibit its use, but owing to the fact that the air comes in direct contact with the heating element in the new design, the efficiency is very considerably increased.



In the cross-section in the figure, it will be seen that the rectangular-shaped box on the centre line contains a number of woven wire resistance mats arranged horizontally one over another. Surrounding this, and insulated from it by slag wool, is a chamber (also insulated on its outer edge), which is really a spiral surrounding the heater. In this spiral, which is square, is a 3 in. by 3 in. tube, which is also a spiral. These tubes form the economiser of the apparatus. Air is blown through the smaller tube by a fan, entering at the top into the bottom of the heater, then up through the wire mats into the space at the top. From this point, by means of a series of ports, the air may be directed either through the wool, which is contained in the conditioning tin, or bye-passed into the annular space surrounding the oven, and thence down into the larger tube of the economiser. This latter method is adopted when the weighing operation takes place, as it would obviously be impossible to weigh the material with a pressure of air under the tin; furthermore, it is not advisable to switch the current off, as even while weighing takes place it is necessary to maintain the air temperature in the oven as normal as possible, otherwise the fabric would absorb moisture from the atmosphere, and so give a wrong result.

The material rests in the tin on gauze or perforated zinc of small mesh, and the usual quantity used for conditioning is ½ lb. This sample is taken from the inside of a bale indiscriminately, and the percentage of moisture in the sample represents the percentage of moisture in that particular bale. Directly above the tin there is a sensitive scale, and it is customary to keep the scale balanced throughout the test by adding weights on the wool side to make up for the loss of weight due to evaporation.



The whole apparatus is designed with a view to securing the highest possible efficiency, and is very thoroughly lagged with asbestos inside and wooden strips outside, and the good heat insulation is shown by noting the temperature of the air at the outlet. The temperature of the oven is maintained at 220° F. throughout the test, and yet the outlet temperature is but a few degrees above that of the inlet. The total radiating surface is 21 sq. ft. A motor consuming about 60 watts is quite large

enough for driving the necessary amount of air through the oven; the heaters consume only one unit per hour, so that the cost for current is but small, and is, in fact, less than that of gas in the most modern type of gas-heated ovens.

As most modern textile mills are fitted up with electrical plant, there should be no difficulty in adopting this type of oven generally, but even if no supply is available, it is a simple matter to run a small dynamo off the line shafting, to which also the fan could be coupled, since in such a case the dynamo would merely replace the motor. The extra cost, therefore, of such an arrangement would be small. One great advantage that this oven has over the gas-heated oven is that it is ready for use in five minutes, whereas it takes from 30 to 45 minutes to thoroughly warm up the other, owing to the fact that a large mass of copper or other metal has to be heated up before the air blast can be applied. It has also the advantage of compactness, and it may be removed from place to place, and used without trouble, so long as there is a supply of current and a plug and flexible available. The temperature regulation is practically perfect, and may be controlled either by regulating the amount of air, or by switching the current on or off, and the apparatus may be used on alternating or direct current at any medium pressure.

NEW MOTOR STARTING SWITCH FOR PRINTING MACHINES

PARTICULARS of a new type of motor starting switch for use with printing machines have been sent to us by the Adams Manufacturing Company, Ltd., of Bedford, and of 106 New Bond Street, London. The principal difficulty with this class of switchgear has been the continued starting and stopping required for "inching," or moving the press forward short distances at a time when "making ready." This is apt to cause most injurious arcing on the contacts of the starting switch. To prevent damage from this cause various devices have been employed. One of the most successful is to use self-acting motor starting rheostats, in which the motor circuit is always made and broken by means of a solenoid controlled switch, which has carbon contacts for circuit breaking, as well as magnetic blowout. For small flat-bed presses, however, the

"IGRANIC" MOTOR STARTER FOR SMALL PRINTING-PRESS MOTORS.

initial cost of self-acting motor starters is often considered prohibitive.

With the object of rendering ordinary hand operated starters suitable, such devices have been employed as carbon auxiliary contacts, magnetic blowouts, and interlocked solenoid switches, &c. These devices have the disadvantage that they only protect the first step, whereas the handle, when "inching," is liable to be pulled over to the third or fourth contact, or perhaps further, and when moved back it draws a destructive arc across the starter steps. As will be seen by the illustration, the new "Igranic" Switch employs an interlocked magnetic circuit maker and breaker, but the essential merit of the arrangement consists in the fact that no matter how far the operator pulls the handle over in a forward direction, the slightest backward movement instantly opens the circuit breaker. Consequently, no arcing can occur on the starter steps because they are dead. The circuit breaker has carbon contacts and magnetic blowout, and will open circuit an infinite number of times without receiving injury.

With this starter, therefore, "inching" may be practised to an almost unlimited extent, and we are informed that a recent prolonged trial in a large printing works under ordinary working conditions left the contacts as good as new. In addition, the interlocking of the circuit breaker with the starter makes it impossible to close the motor circuit except with all the starting resistance in circuit, so that the motor receives proper protection, and the starting switch may be said to be practically "fool-proof."

ELECTROMETALLURGY AND ELECTRO-CHEMISTRY

AT the Imperial International Exhibition, in the Machinery Hall, Messrs. Cowper-Coles Co., Ltd., have an interesting exhibit on a very tastefully arranged stand. Electrolytic steel is shown, and a bowl spun up from iron which has been electrolytically deposited directly from the ores. This part of the exhibit also includes samples showing the difficulties which had to be overcome before it was possible to produce dense and coherent deposits. Some of the first produced iron shows a very noduly effect and different thicknesses at the two ends of the cathode.

There is also an interesting display of electrolytic zincing and also of "sheradising." With sheradising a finer effect is produced, and it can also be more readily employed for inlay work. In reference to the electrolytic galvanising, it is interesting to note how the anodes become fitted and unevenly corroded. There are also some extremely good examples of parabolic mirrors which are electrolytically produced for searchlight purposes. These, of course, are much better than glass reflectors, because a bullet striking them makes a clear-cut hole instead of smashing the whole mirror as is the case with glass. A parabolic electro-deposited mirror is shown. There is also an interesting glass reflector upon which concentric gold and silver bands have been deposited. Iron articles coated with electrolytically deposited copper makes a very pretty exhibit. Also plating with silver cadmium alloys, that is, employing a bath containing both silver and cadmium. The exhibit is certainly well worth visiting.

In the Applied Chemistry Section, just outside the Court of Honour, on the left-hand side, the Castner Kellner Co. show an interesting exhibit of caustic alkali, bleaching powder, and other substances obtained by the electrolysis of common salt. The specimen of sodium is especially noteworthy, being sealed up in a glass bulb. It was then melted, and one sees the very beautiful, silvery appearance of pure sodium and the crystalline effect produced when it solidified. The Weston Chemical Co. show chlorinated products obtained by reaction with electrolytic chlorine and acetylene. We believe that it is due to the new Patent Act that these substances are being manufactured in this country.

During the year 1908 the output of calcium carbide for the whole world was about 200,000 tons. This was manufactured by 70 individual firms, employing altogether about 300,000 h.p. The United States, with its great water power, manufactured 38,000 tons; Italy, 32,000 tons; France, 27,000 tons; Norway, 25,000 tons; Austria-Hungary and Switzerland, 20,000 tons; and Sweden, 12,000 tons; the other nations only comparatively small quantities. The largest firms are in Hafslund and Odde in Norway, and manufacture about 20,000 tons. Germany uses very large quantities of carbide, 33,800 tons, and only manufactures 9,000 tons; consequently there is a large import trade. Russia apparently does not use much, because there are no manufactories, and the import duty is 38 francs per 100 kilog.

An Instrument for Weighing the Loads on Ships.—A demonstration of a new device called the "Porhydrometer" was given on Monday morning at the Temple Pier, London. The instrument is for weighing the dead weight placed on board or removed from any ship, barge, or other floating vessel to which it is fitted, and is based upon the principle that a floating body displaces a quantity of liquid exactly equal to its own weight. In the centre of the vessel a vertical tube is fitted extending from well below the light draft water line to well above the load line, and connected by a pipe with the outside shell of the vessel, so that when the valve or cock is opened the water in which the vessel is floating has free access to the vertical tube, and rises in it to exactly the same level as outside the vessel. Inside the tube is fixed a vertical float, which, having exactly proportionate horizontal areas at the various immersions to the areas of the planes of flotation at the same drafts or immersions of the vessel, has an exactly similar displacement, and reduces the enormous weights dealt with to a measurable quantity. The float being immersed in the same liquid to the same extent as the vessel itself, by its consequent exactly proportionate displacement, loses an amount of weight exactly equal to its displacement. This loss of weight disturbs the balance of levers, and is exactly registered or counter-balanced by moving the weights along the steelyard, giving a correct reading of the weights placed on board the vessel or of the weights removed. Neither transverse inclination nor change of trim will affect the accuracy, as the tube is fixed in the centre of the vessel. The porhydrometer can be fitted to any vessel. No calibration is required, but the float must be shaped specially for each vessel. We are informed that the Italian Government has approved the invention after testing it; and, further, it has decreed that the Customs shall accept as correct the weight of cargoes measured by the instrument. At the demonstration the instrument was shown working on a 200-ton barge, and it should find considerable application in connection with the loading and unloading of coal, as the usual weighing in small quantities would be rendered unnecessary. Further particulars can be obtained of Mr. E. Beresford, of 66 Carlisle Mansions, Carlisle Place, London, S.W.

A METAL FILAMENT LAMP PATENT CASE

AN action by the "Z" Electric Lamp Manufacturing Co., Ltd., against Messrs. Marples, Leach & Co., for infringement of their patent No. 21,654 of 1906, was mentioned before Mr. Justice Warrington in the Chancery Division of the High Court on Friday. The patent, which is dated April 2nd, 1907, was granted to Dr. Hollefreund & Co., of 30 Mullerstrasse, Berlin, and relates to "Improvements in the Manufacture of Filaments for Incandescence Electric Lamps." The complete specification is as follows:—

In the manufacture of incandescence electric lamp filaments from metallic compounds it is desirable to obtain the finished filaments as free from carbon as possible, because if even a small amount of carbon be contained in filaments, it interferes very prejudicially with the strength and serviceableness thereof. It has been proposed to employ nitrogen for removing the carbon, but it is difficult to work, on a commercial scale, the processes hitherto proposed for employing nitrogen for the purpose of obtaining the filaments free from carbon, and they rarely allow of the carbon being completely removed without the means employed for this purpose attacking the metal from which the filament is formed.

The present invention provides means, which can be carried out on a manufacturing scale, by which even the last traces of carbon in the filament are removed in such a way that the metal of the filament does not suffer thereby. This invention consists in effecting the decarbonisation of the filaments by means of gases produced *in vacuo* by heating phosphorus compounds containing hydrogen and nitrogen and also optionally containing oxygen or sulphur, such, for example, as phospham, phosphoramide and phosphoraminic acids, phosphoric imidoamide, and phosphorus sulphotriamide, with the addition of phosphorus if necessary. Of these substances, phospham is especially suitable for the purposes of this invention because not only is the nitrogen contained therein released *in vacuo* from its combination even at a comparatively low temperature and when set free forms with the carbon, cyanogen, or other similar, or oxidised, cyanogen compounds, but likewise the phosphorus, which is at the same time set free, is capable of fixing the oxygen still present, or of exerting its reducing action upon metallic oxide should it be in the filament. Some red phosphorus may also be added, especially in cases where oxide may be present in the filament in appreciable quantities.

The following are examples of the way in which this invention can be performed presuming phospham to be employed, but the invention is not limited to these examples. To the metallic powder, from which the paste for squirting the filaments is prepared, a little phospham is added and the mixture is ground thoroughly and a paste prepared analogously to the usual manner of preparing pastes for making filaments. In making this paste the amount of phospham added depends upon the nature of the binding agent employed; the more carbon it contains, the greater being the amount of phospham added. The amount of carbon contained in the finished paste usually amounts to about 4 per cent. if tar be employed as the binding agent. The filaments can be formed in any suitable manner, for example, by squirting in the usual way. The action of the phospham takes place directly in the filaments when the said filaments are raised to incandescence *in vacuo*, they becoming absolutely freed from carbon, their strength not being in any way injuriously affected. In another way of carrying out this invention, the phospham is heated outside the filaments and the gases therefrom are allowed to act upon the said filaments externally. This method is preferably carried out by first producing as complete a vacuum as possible in a furnace in which the filaments are placed together with phospham and in which they are to be raised to incandescence. The furnace is then heated to about 130° C. in order to remove the water and the decomposition products produced up to this point. The cocks connecting the pump to the furnace are then closed, and the furnace is slowly heated up to from 800° to 1,000° C. The phospham is thus decomposed, and the gases produced are under a pressure of a column of mercury of a few millimetres, which depends upon the amount of the phospham employed, which amount depends upon the binding agent which has been used for the preparation of the paste from which the filaments were made. If the paste contained a large quantity of carbon, then a correspondingly large amount of phospham is employed, and the heating action is correspondingly prolonged. The filaments treated in this manner are also completely free from carbon and solid impurities.

Instead of proceeding as aforesaid the treatment may be effected in the well-known receptacles in which the raw filaments are incandesced, or in the glass bulb of the incandescence electric lamp. The filaments are first dusted over with phospham or otherwise analogously coated, for example, by painting them with fine phospham powder treated with a suspending medium and then the filaments are incandesced, and the gases are given off from the phospham. Or the phospham may be brought in conjunction with a neutral auxiliary body, into the immediate neighbourhood of the filaments and be there vapourised, either directly by special heating, or indirectly by the heat from the filaments. Where the auxiliary body consists of metal, the arrangement may be so contrived that it forms a part of the circuit to the filaments. The cross-section of the auxiliary body is then so chosen that it only glows dully when the filaments are at the brightest white heat, so that the phospham acts with full effect.

If a filament already inserted in the lamp is to be decarbonised according to the present invention, the operation is preferably carried out in the following way:—Fine phospham powder is suspended, preferably in alcohol, and applied to the filaments before they are fused in the ends of the conductors, or the phospham compound may be applied to the leads, supports, holders, or the like. After the lamp has been put on the pump and a vacuum created therein the connection between the lamp and the pump is closed and the filament is incandesced by an electric current. By this means the phospham, or its equivalent, is vapourised so that the action hereinbefore described takes place. In this case also the phospham, or the equivalent, can be heated outside the lamp in a chamber which can be put into communication with the lamp by an arrangement such that the vacuum existing in the lamp is not damaged. In place of using solid phosphorus compounds, the gas mixtures corresponding to the decomposition products resulting from the heating *in vacuo* of the said phosphorus compounds can be employed.

The claims are as follows:—

1. In the manufacture of incandescence electric lamp filaments free from carbon, the employment of phospham, or equivalent phosphorus—hydrogen—nitrogen compound, or an oxygen, or sulphur, compound thereof; either in the production of the raw filaments, or by causing its decomposition products obtained by heating *in vacuo*, to act on the raw filaments.

2. In the manufacture of incandescence electric lamp filaments in accordance with the preceding claiming clause first completely exhausting the vessel in which the filaments are to be decarbonised in the presence of phospham, or its equivalent, and then heating up to about 130° C., then closing the connection with the air pump and slowly heating up to from 800° to 1,000° C.

3. The treatment of incandescence electric lamp filaments for the removal of carbon therefrom in the manners hereinbefore described under the several examples.

As stated above, the action in question was mentioned before Mr. Justice Warrington on Friday, an application being made by Mr. Colefax on behalf of the "Z" Lamp Co. for further particulars in amplification of the defendants' pleadings in reply to the plaintiffs' allegations. Mr. Colefax claimed that the particulars of objections to the action were too general in character, it not being stated to what claims any of the objections related. The pleadings did not talk of prior user, but of want of subject-matter, without detailing in what respect there was lack of subject-matter. It was stated that the claims in the patent could not be substantiated and were unworkable. He wished to know in what respect this was so in order that he might know the case he had to meet. The objections really related to the result, and not to the theory of the patent, and therefore he had a right to have further details. It was disputed that "phospham," as claimed, decomposed at a comparatively low temperature. At what temperature was it suggested that phospham did decompose? He was entitled to know this, as presumably the defendants had carried out experiments, and his clients wished to carry out counter-experiments to disprove this. If he could not disprove it, then it would be open for him to drop the action, but he must know what case he had to meet. It was also stated that the directions given in the patent were insufficient to enable a skilled workman to act upon them. In what way were they insufficient?

Mr. TIRRELL, K.C., for Messrs. Marples, Leach & Co., said that he had personally drawn up the pleadings, and anything more complete he could not imagine. It was claimed that the subject of the patent was not a proper one for letters patent. This applied to all the claims. None of the reactions described in the patent took place at all. It was a figment, and the point of insufficiency of specification also arose in this connection. No information was given as to the reactions, nor sufficient direction given for a skilled workman to carry out the work. Neither was information given as to the decomposition products. Until quite recently phospham was an unknown chemical quantity. He regarded the application as oppressive, and relied upon a previous judgment of the Appeal Court that, where all the information in possession of the defendants was given in the pleadings, nothing further could be asked for. He applied his objections to the whole of the patent.

Mr. JUSTICE WARRINGTON said he did not think it necessary that further information should be given in the defendants' pleadings, and dismissed the summons. He would, however, grant leave to appeal in view of the point being one of some legal importance.

SELLING GAS ENGINES

WE have received from a correspondent a letter written by a firm of gas engine-makers to an intending customer, who was hesitating in his choice between a gas engine and an electric motor run from the corporation mains. We have been requested to publish the letter, and give it below:—

DEAR SIR,—*Re* our conversation with you this afternoon, we have pleasure in giving you figures showing the comparison between your using gas engine or electric motor to drive your printing machinery.

The number of hours you run per day being 8½ for 5½ days per week, for 50 weeks per year, will equal 2,612½ hours. A gas engine of 8 b.h.p. running these number of hours at full load will consume 120 cubic ft. of gas per hour, which equals 313,500 cubic ft. of gas, and, taking gas at —— at 1s. 8d. per thousand cubic ft., your yearly account will equal £26 2s.

With regard to the electric motor, we may say an electric unit is equivalent to 1½ b.h.p.; but, as you know, the current is run through the meter before entering the coils of the motor, and the loss of current in very large motors is estimated by a prominent local electrical engineering firm at about 20 per cent., that is to say, should your meter register, say, 10 units, you would only be developing 8 units of power, 2 units being absorbed in the coils. It is therefore not unlikely that, for every unit registered at your meter, you would only develop 1 b.h.p.; but taking 1 unit to equal 1⅓ b.h.p., we are giving the motor the benefit, so that an 8 b.h.p. motor will consume 6 units of electricity per hour, and taking electricity at 2d. per unit for the same number of hours run as the gas engine, it works out at 1s. per hour, or £130 12s. 6d. per year.

You will notice there is a tremendous difference when looking at the figures in the most favourable light, the saving being £104 10s. 6d. per year.

The average life of a dynamo or motor is five years (that is to say, the armature, which is the main part of these machines); the tremendous speed at which they go is accountable for the short life.

We shall be glad to go into the matter again with you when our representative calls upon you next Monday, and we trust you will now be able to favour us with your valued order, which we can assure you would have our best attention.

Yours faithfully,

It is only fair to point out that, if gas is taken at the low rate of 1s. 8d. per thousand, electric power supply should not be taken for comparison at so high a figure as 2d. per unit, as the charge would not be likely to exceed 1d. for power for a consumer with an 8½-hour load factor. This would bring the £130 for the annual cost of the electric power to £65, which, when compared with £26 for the gas engine, only leaves £39 difference out of which to pay the cost of additional oil and repairs, both of which will be far heavier in the case of the gas engine, the wages of the attendant who would be required, and last, but not least, the heavier depreciation and the interest on the larger initial capital outlay. The statement that the average life of a motor is five years is, of course, absurd. There are sometimes circumstances in which the cost of working with gas engines may even be cheaper than with electric motors, and it is to be regretted that the enthusiasm of local agents for gas engines should tempt them to employ such methods as are exemplified by the above letter.

Municipal Tramways Association.—The annual conference of the Municipal Tramways Association, of which Mr. A. L. C. Fell, the Chief Officer of Tramways to the London County Council, is president for the current year, will be held in London on September 22nd, 23rd, and 24th next. The Finance Committee report that it has been customary in the large provincial towns where the association has held its annual conference in past years for the Corporation to recognise, officially, the conference, and to offer every facility to the members for free travel on the tramways, &c., and the Highways Committee have accordingly authorised their chairman (Mr. A. Shirley Benn), their vice-chairman (Mr. A. Pownall), and Mr. W. J. Squires to make any arrangements which they may consider desirable in connection with the conference. The Highways Committee have suggested that their chairman and vice-chairman, Mr. W. J. Squires, Mr. W. Whitaker Thompson, and Mr. Henry Ward should be appointed representatives of the Council at the conference, and the Finance Committee concur in and recommend the suggestion to the Council.

THE ECONOMY OF GAS ENGINES

A NEW show-card which is being issued by the Key Engineering Co. contains an ingenious calculator in the form of a circular slide rule, by which the percentage gross profit on the extra capital outlay for a gas plant as against a steam plant can be calculated, knowing the extra capital cost per b.h.p., the cost of fuel available, and the hours per day the plant will be run on full load or equivalent. The calculation is based on the fact that the fuel consumption will be at least 1 lb. per b.h.p. less with a gas installation than with steam, and assumes that the cost of repairs, labour, stores, &c., is the same in both cases. The converse operation of ascertaining the additional capital expenditure justifiable for certain interest and depreciation charges, may also be performed. The appliance should certainly have the effect of directing attention to the possibilities of economy obtainable by gas plant to many who have not gone into the question.

CORRESPONDENCE

ELECTRIC LIGHTING ACTS (AMENDMENT) BILL.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—Referring to my letter, which you were good enough to insert in your last issue, I am now glad to be able to report that as a result of the efforts which have been made, substantial amendments have been obtained in the Bill now passing through Parliament.

Clause 6 has been altered so as to make it quite reciprocal between Local Authorities and Companies.

Clause 13—relating to audit of accounts—has been struck out, and the following Clause has been substituted:—

"The Board of Trade shall from time to time make a return to Parliament, giving such particulars as they may think proper with regard to the reports made by any auditors appointed by them to audit the accounts of any undertakers and any action taken on such reports by the Board and by the undertakers."

Clause 2 has also been amended with regard to sub-stations.

The Bill passed the Standing Committee on Tuesday last week, and until we see a revised print we cannot be sure that all points have been satisfactorily met, but it is believed that there will be no further necessity to oppose the passing of the Bill.

The Bill is not entirely satisfactory, because many important matters referred to by the Select Committee of 1898 have not been dealt with, but the Bill contains some good points, and the particularly dangerous clauses have, it is hoped, been satisfactorily amended.

Yours faithfully,

E. GARCKE.

Electrical Federation Offices,
Kingsway, London, W.C.
21*st July*, 1909.

Delay on the Liverpool and Southport Line.—Owing to the temporary failure of the supply, considerable delay was occasioned on the Liverpool and Southport (electric) line of the Lancashire and Yorkshire Railway on Thursday morning last. The cause of the failure is said to have been the breakdown of a cable. Steam locomotives were attached to the trains and a slightly reduced service was maintained in this manner during the afternoon and evening.

Street Lighting in the City of London.—With reference to the question of public lighting in the City, referred to at length in our last two issues, a representative of the *City Press* has interviewed representatives of both the City of London Electric Lighting Co., and the Charing Cross, West End, and City Electricity Supply Co. on the matter. Mr. J. Cecil Bull, joint managing director of the City Co., said that his company offered two years ago to do the whole of the public lighting in the City at a reduction of 30 per cent., a saving of over £4,000, and at the same time to settle the question of the agreements made with the old Brush Co. Two better offers have, he said, subsequently been made by his company. Mr. Seale, secretary and manager of the Charing Cross Co., and Mr. Thorpe, of their engineering department, pointed out to the representative of our contemporary that the price of £16 10s. per lamp per annum for the Keith inverted gas burners, as used in Fleet Street, could not be compared with the £17 10s. for the experimental arcs in Cannon Street, for the reason that 11 of the latter would give the same amount of light as 16 of the former. It was also pointed out that the sub-committee of the City of London Corporation, which recently reported in favour of gas, seemed to have been convinced by what was taking place in Berlin, but it was an interesting point that the Berlin gas works, which were owned by the municipality, charged street lighting at 1s. 4½d. per 1,000 cubic feet, and the private consumer 3s. 10d.

STUDENTS' VISIT TO GERMANY

By E. W. Moss

THE ninth tour of the present series of the Students' Section of the Institution of Electrical Engineers was this year arranged for Germany, and a party of thirty-eight left London on Friday, July 9th, for Berlin. The visits commenced on Monday, July 12th, when the party went over the works of the Allgemeine Elektricitäts Gesellschaft. The apparatus factory was first seen, where fuses, instruments of all kinds, small switches, and arc lamps, &c., are made. These works are comparatively new, and are most up to date. All machines are driven by separate motors, and amongst them was noticed an interesting machine for automatically making small springs, and a mechanical screwdriver for putting screws into small pieces of apparatus. This machine automatically picks up the screws from a pile and passes them to the position where the apparatus requiring the screws is held. They are then seized and screwed up. A great deal of enamelled wire is being used by the firm for relay windings and for arc lamp solenoid winding.

The machine shop was next visited, and various sized machines were seen in course of erection, up to 7,500 kw.; the firm also have on order four 12,000-kw. machines for 40,000 volts for the Victoria Falls Power Co.

After visiting these shops and the drawing offices, the party partook of light refreshments, after which Mr. Nadaud, Chairman of the Students' Section, in a short speech, thanked the various members of the A.E.G. staff who had so kindly shown the party over the works, and particularly Mr. Mackay, head of the Literary Department, who had made such excellent arrangements for the visit.

The party then drove to Oberschönewiede, and visited the automobile works of the company. After this they were entertained to lunch, Dr. Heilbrun, of the Literary Department, being in the chair. Before leaving, the party visited the rubber and cable works, and the copper-wire drawing mills of the company, where many interesting operations were witnessed; and also the adjoining power station of the Berlin Electricity Co.

The Tuesday morning was spent in visiting the turbine works of the A.E.G., where a large number of A.E.G.-Curtis machines were seen in course of construction. The central station supplying the works was also seen, this containing two 2,000 kw. turbo-alternator sets at 2,000 volts, and one small turbine-driven exciter.

In the afternoon a visit was paid to the mechanical and electrical departments of the famous Königliche Technische Hochschule at Charlottenburg. First was seen the boiler house and then the mechanical laboratory, where various types of engines were noted for testing. Most interesting was an experimental reversible turbine, with straight blades, which, however, from the point of view of steam consumption, has hardly been a success; and also a pump with various arrangements fitted for giving bad results, so that a student may see the effect of faults of a known character on the efficiency and working of the machine. This same process is followed in other departments, viz., a student is shown not only the performance of a good machine, or a good design, but is also shown the effects of a bad design, and has to examine the effects of faults in various machines. The electrical research laboratory under Professor Reichel was next seen, this being fitted with various machines, among which were noticed a model surface-contact system, a high-tension transmission scheme, a model electric lift, and a testing set for testing insulators under various conditions up to 400,000 volts. In the next laboratory (for elements of machinery, under the direction of Professor Kammerer) an apparatus for research into the constants and properties of belts for driving machinery was demonstrated to the party, this being a new machine designed specially for this research. The mechanical laboratory was seen, and then Professor Meyer showed the party through the material testing department. The electrical laboratory contains a number of small machines for testing, and sixteen benches for students; this, however, is not considered suitable, and a new laboratory is to be built at a cost of two million marks. Professor Heyn showed the party through the technology department, containing apparatus for experimenting on recalescence points of iron and steel, various small machines, *e.g.*, a turret lathe, planing machine, milling machine, lathe, &c. There is no large workshop, as is usual in English colleges, as all students have to spend one year in works before entering the college.

Thursday morning, July 14th, was spent visiting the works of Messrs. Siemens Schuckert at Nonnendamm. In the large machine shop a number of turbine machines were seen, and also several large slow-speed generators. This shop contains a large bed with movable machines for performing various operations on large parts brought to the bed. The small accessories department contained several interesting machines, and there was noticed under construction a number of spirally wound choking coils for lighting arresters on long transmission lines, also various lifting gears, and motors for motor-cars, with radial commutators. The cable works were next seen, and the various machines inspected, after which the party were entertained to lunch by the company. After lunch Mr. R. C. Plowman, Chairman-elect of the Students' Section, thanked the company on behalf of the party for allowing the visit, and also the gentlemen who had so kindly shown the party through the works.

The party then proceeded to the works of Messrs. Dr. Cassirer & Co. These works are quite up to date in every department, and it is claimed that for their size, the staff numbering about four hundred, they have a larger output than any other German cable works. They are arranged so that the material always travels in one direction through them, *i.e.*, the raw material enters at one side of the works, and the finished article leaves at the other. Specially cool underground cellars are used for storing raw rubber and finished wires. An interesting machine noticed was one for stranded cables, in which, in order to save space, the bobbins of wire were not mounted in the usual way, *i.e.*, to travel round in a circle one after the other on a large framework whilst the cable is allowed to travel forward, but in which the bobbins were arranged on a rack whilst the cable, in travelling forward, was twisted. Various processes in cable manufacture were seen, the manufacture of insulating tapes, and the test room, where a piece of cable was seen tested to its breaking down point.

An interesting visit was paid on Thursday morning to the Reichsanstalt, where the laboratories for testing standard cells, for standardising thermometers, gauges, various electrical meters, and for high-temperature measurements were seen. Researches are being carried out on cathode rays, and on uniform magnetic fields. In the small sub-station a mercury arc rectifier was seen supplying 10 amps. at 250 volts, and also a 160-pole alternator for giving a frequency of 3,000 alternations. Apparatus is also installed for testing insulators up to 200,000 volts under an artificial rain and various other conditions.
